CITY OF LONDON ELECTRIC LIGHTING COMPANY, LIMITED.

Directors: Sir David L. Salomons, Bart., chairman; the Earl of Suffolk and Berkshire; Joseph Bevan Braithwaite, jun.; Edward Lucas; Colonel B. H. Martindale, C.B.; Frederick W. Reynolds. Frank Bailey, engineer to the Company. J. Cecil Bull, manager and secretary.

Report of the directors to be presented to the shareholders at the ordinary general meeting of the Company to be held at Winchester House, Old Broad street, E.C., on Wednesday, February 27, 1895, at 2.30 p.m.

Capital.—The expenditure on capital account during the year ended December 31, 1894, amounted to £280,532. 9s. Details of this further outlay are given in the capital account. During the year 5 per cent. debenture stock to the extent of £300 000 has been issued at premiums amounting to £71,000. The first issue of £100,000 is already quoted in the Stock Exchange official list, and application has been made for a quotation for the second issue of £200,000. The directors have been advised that owing to the debenture stock having been made redeemable at £125 per centum after December 31, 1910, the sanction of the shareholders is necessary to the issue of the further stock required to complete the £400,000 mentioned in the original prospectus, and a resolution for this purpose will be submitted to the shareholders.

Revenue.

	£	s.	d.	£	s.	d.
The total revenue for the year was				£69,380	3	3
From which must be deducted the following items charged against revenue:						
Expenses of generation and distribution	£27,983	17	3			
Rents, rates, taxes, and general charges	6,531	3	6			
				34,515	0	9
Leaving a net revenue of				34,865	2	6
To which must be added the balance brought forward from 1893				3,041	14	9
Making a total available revenue of				37,906	17	3
Of this sum the following amounts have been distributed:						
(*a*) Interest on debenture stock to December 31 last	3,154	3	4			
(*b*) Interim dividend on £400,000 6 per cent. preference shares for half-year to June 30 last	12,000	0	0			
				15,154	3	4
Leaving for further distribution				£22,752	13	11

The directors now recommend the following dividends for the past half-year—viz., 6s. per share on the preference shares, being at the rate of 6 per cent. per annum, and 5s. per share on the ordinary shares, being at the rate of 5 per cent. per annum. This will absorb £22,000, leaving a balance of £752. 13s. 11d. to be carried forward. Out of the premiums already received on the issues of debenture stock, the directors have decided to write off the whole of the expenses in connection with the issues of ordinary and preference shares, debenture stock, and other preliminary matters, amounting in all to £19,064. 18s. 4d., and to transfer the sum of £1.595. 11s. to the reserve fund, leaving a balance of £44,923. 18s., which it is proposed for the present to carry forward. The necessary provision for depreciation in accordance with the City of London Electric Lighting Act, 1893, has been made. Notwithstanding repeated applications the local authority has not yet given consent as required by the Telegraph Act, 1892, to the use of certain tubes for telephonic purposes. Negotiations are still proceeding. The generation and distribution expenses for the year, including repairs and renewals, were 46 per cent. of the earnings, as compared with 54·2 for 1893. Revenue is now being earned at the estimated rate of over £105,000 per annum gross. The rapid progress made in the Company's business will be readily seen by the following table:

	End of Dec., 1892.	End of Dec., 1893.	End of Dec., 1894.
Estimated gross revenue from private lighting	£16 193	£45,738	£88,000
Estimated gross revenue from public lighting	11,259	12,933	13,600
Number of 8-c p. lamps connected	20,241	65,341	135,460
Number of customers	242	1,080	2,740

Lands and Buildings.—The main buildings now finished will accommodate plant of sufficient capacity for at least 300,000 8-c.p. lamps connected. Possession of Rose's Wharf and premises adjoining the Bankside station has just been obtained; this site will be utilised in due course for the business of the Company. The whole of the 22 transformer stations are now in operation; they will accommodate equipment for the service of at least 400,000 8-c.p. lamps connected.

Generating Plant.—The plant already in position is of a capacity of 150,000 8-c.p. lamps, and the further machinery in course of construction by the contractors will be erected during the current year. The arc lighting plant has worked satisfactorily throughout the year. The total number of units sold during the year was 2,602,217.

Street Work.—This work is now practically complete. Further expenditure for cables will be limited to primary mains, feeders, and service conductors, which will be provided as from time to time required.

Private Lighting.—Nearly 3,000 private consumers, representing a total of 142,500 8-c.p. lamps, are being supplied with current. Applications continue to come in satisfactorily, the total received to date being equal to the supply of current for 151,000 8 c.p. lamps.

Public Lighting.—The Company is still awaiting the order of the Commissioners of Sewers to proceed with the lighting of the lesser streets, for which the necessary plant was in position a year ago.

Staff.—The directors have appointed Mr. Frank Bailey to be engineer to the Company in the place of Mr David Cook, resigned; Mr. J. Cecil Bull, the secretary, to be also commercial manager.

Directors and Auditors.—In accordance with the articles of association, two of the directors, Mr. Edward Lucas and Colonel B. H. Martindale, C B., retire, and, being eligible, they offer themselves for re-election. Messrs. W. H. Pannell and Co. retire, and, being eligible, offer themselves for re-election.

Dr. CAPITAL ACCOUNT, DEC. 31, 1894.

CITY OF BATH ELECTRIC LIGHTING AND ENGINEERING COMPANY, LIMITED.

The fourth annual general meeting of this Company was held at Bath, Mr. T. O. Callender occupying the chair.

The **Chairman**, in moving the adoption of the report and accounts, which were published in our issue of 8th inst., said the directors could come before the shareholders with a certain amount of confidence and satisfaction, and he was sure next year they would have better results to lay before them. They were always sorry not to be able to recommend a dividend: there was sufficient to pay a small one, but after careful consideration they thought it would be the true policy to carry forward the balance. Referring to the improvement of the plant, the Chairman said they had fitted up some of their furnaces for liquid fuel, which already had been of the greatest advantage in the difficult season through which they had passed. It was their intention to extend that system a little later on, and they also saw their way to improving the plant and appliances inside and outside the station. They thought it would be money well spent. It was a matter for congratulation that the citizens were adopting the light more freely than in the past. He referred

Digitized by Google

in terms of warm praise to the efforts of their engineer and his staff, especially during the flood, and said the directors wished to bear public testimony to their appreciation of Mr. Metzger's services. As the question of the provisional order was quite *sub judice*, it would be better to say nothing about it. They had every reason to be satisfied with what had been done, and they were quite content to leave it in the hands of Mr. Titley and Mr. Morse (the London agent) and the Board of Trade.

Mr. Van Tromp seconded the motion, which was carried.

Mr. T. O. Callender and Mr. C. J. Wharton, the retiring directors, were re-elected.

ISLE OF MAN TRAMWAYS AND ELECTRIC POWER COMPANY, LIMITED.

Directors: Alexander Bruce, J.P. (chairman), Ballaquayle Villa, Douglas; Frederick George Callow, Ballacurrie, Onchan, Douglas; John Allen Mylrea, J.P., M.H.K., Derby-terrace, Douglas; Dr. Edward Hopkinson (Messrs. Mather and Platt, Limited), Manchester; Alfred Jones Lusty, 150, Leadenhall-street, London; William Parke J. Pittar, The Cliffe, Douglas; Richard Farrell, LL.D., Victoria-road, Douglas. J. Aldworth, manager. W. E. Young, secretary.

Report of the directors presented to the shareholders at the ordinary general meeting of the Company held on Wednesday last.

The available profit from May 1 to December 31, 1894, including a sum of £526. 12s., being premiums on shares sold, amounts to £11,034. 0s. 10d. Out of this profit an interim dividend of 6 per cent. per annum on the preference shares, and 7½ per cent. per annum on the ordinary shares, amounting to £4,213. 15s. 3d., was paid for the half-year ending October 31; also a sum of £1,666. 13s. 4d., being interest on debentures up to December 31 last, and £43. 9s. 10d. interest on mortgages (balance), making a total of £5,923. 18s. 5d. The directors recommend that a further dividend at the rate of 6 per cent. per annum on the preference shares and 7½ per cent. per annum on the ordinary shares, for the remaining portion of the financial year ending December 31, amounting to £1,437. 10s., be now declared and payable on the 28th inst.; that £2,000 be carried to a reserve and renewal fund; and that the balance of £1,672. 12s. 5d. be carried to profit and loss new account for the present year. Owing to unavoidable delays, the passenger traffic between Groudle and Laxey was not commenced until July 28 last, and this part of the line being the most important section, the profits are much less than what may be anticipated in future years. Last season, owing to the limited number of motor cars, the management was unable to cope with the passenger traffic. The Board, therefore, has ordered four new open motor cars of an improved type and larger carrying capacity from Messrs. G. F. Milnes and Co., Birkenhead, and the electrical equipment from Messrs. Mather and Platt, Limited, Salford. The passenger traffic on the electric line during the winter months has exceeded the expectations of the directors, who have also to report that they are confident that the revenue to be derived from goods and merchandise traffic will be substantial. Arrangements are being made to meet the wants of the districts through which the tramway passes, together with the surrounding neighbourhoods. Negotiations are pending for the erection of a convenient station and all necessary accommodation at the Laxey terminus, and arrangements are now in progress for an approach road to the terminus. This road will lead into the heart of Laxey, and will meet the fullest demands for vehicular and pedestrian traffic. Convenient waiting-rooms at important points along the line will also be shortly erected. An arrangement has been made between this Company and the Derby Castle Company for the erection of a large waiting-room and other accommodation at the Douglas terminus. After providing for the dividends on preference and ordinary shares, and interest on debentures up to December 31, and carrying £2,000 to reserve and renewal fund, an available sum of £4,080 11s 10d (over and above the balance being carried forward, of £1,672 12s. 5d.) remains in hand to meet any necessary outlay on rolling-stock, etc. The retiring directors this year are Messrs. Alexander Bruce and F. G. Callow, both of whom are eligible and offer themselves for re election. The auditors, Messrs. Aldred, Turner, and Co., also retire and offer themselves for re-election.

Electrical Engineer's Report.

I have made an inspection of the plant at the generating stations at Douglas and Laxey, and also of the line and rolling-stock. I have much pleasure in reporting that I have found the whole in good condition, and maintained in a manner which reflects much credit upon the general manager and his engineering staff. I also, in particular, examined the accumulator station at Groudle. The battery is in excellent condition, and has been of great service, not only as a reserve and regulator of the load upon the engines, but also for working the winter traffic through a large portion of each day. thus reducing the time during which the generating plant at Douglas need be worked, and consequently effecting a great economy in working expenses. Edward Hopkinson.

	£183,044	19	1

The first annual meeting was held on Wednesday at Douglas.

Mr. A. Bruce, chairman, in proposing the adoption of the report, congratulated the shareholders on the magnificent position of the Company, and pointed out that with the interim dividend already paid and that proposed the shareholders were paid the handsome dividend of 12 per cent. on the preference and 15 on the ordinary shares. They proposed to carry forward £2,000 to reserve, and £1,672 to profit and loss. He alluded to the prospective public improvements, which would increase the number of visitors and add to the revenue of the Company.

The report was adopted, and Messrs. A. Bruce and F. G. Callow were re-elected directors.

Mr. J. Aldworth, the manager, said that during the eight months the system had been working, a million and a quarter persons had been carried without injury to life or limb, showing the efficiency with which the line was worked.

CAMBRIDGE ELECTRIC SUPPLY COMPANY, LIMITED.

Directors: D. Munsey, Esq. (chairman), the Hon. C. A. Parsons (managing director), Sir B C. Browne, Wm. C. Hall, Esq., P. W. Latham, Esq., M.D., John B Simpson, Esq., G. Whitmore, Esq John H. Barker (general manager and secretary).

Report of the directors to be presented to the shareholders at the third annual general meeting to be held at the offices of the Company at Cambridge on Wednesday, February 27, at 12 o'clock.

During the last 12 months lamps equivalent to 3 644 of 8 c.p. have been connected to the Company's mains, making a total at the present time equal to 11,644 lamps of 8 c p. The electric light has during the year been extended throughout Caius College and Sidney College. There is every prospect of a large increase in lamps during the present year. During the past year 3,688 yards of main conduit pipe has been laid in Newnham and other districts, making at the present time a total of 12,146 yards. Since October, 1894, the supply of current has been continuous day and night. In order to maintain the supply most economically, as well as to meet the increasing demand for current, your directors have decided to add a small day-load generating plant and an additional boiler. The Company has made a profit on the year's working of £933. 1s. 1d., which, added to £268. 10s. 11d. brought forward from last year, leaves a balance of £1,201. 12s. Your directors therefore advise the payment of a dividend of 2½ per cent, absorbing £575. 18s., which, with £350. 17s. 7d. debenture interest, leaves £274. 16s. 5d. for depreciation, writing off, etc. Your directors anticipate that the further increase of lamps during the present year and the addition of the day-load plant will enable them to recommend an increased dividend for the current year. Sir B. C. Browne and Mr. D. Munsey retire by rotation, but are eligible, and offer themselves for re-election. The auditor, Mr. Arthur Rutter, also offers himself for re-election.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Plymouth.—The Corporation invite tenders by the 28th inst. for the supply of, among others, oils and paints and indiarubber goods.

Seaham (Durham).—Tenders are invited by the 28th inst for lighting the streets and roads of the parish with gas or electricity, for the Seaham Parish Council. Tenders, sealed and endorsed "Parish Lighting," to be sent to the chairman, Rev. D. W. James, of whom any further information may be obtained.

Islington.—Tenders are invited for the supply of alternate-current meters and converters by the Vestry of St. Mary, Islington. Specifications and full particulars may be obtained on application to the electrical engineer, 50, Eden-grove, Holloway, N. Applicants will be required to deposit the sum of £1. 1s., which will be returned on receipt of a *bond fide* tender.

Warrington.—The Sanitary Works Committee of the Corporation desire tenders by the 25th inst. for the supply of a water-tube boiler (of the Babcock and Wilcox type), proposed to be erected at Longford depôt. Specification and drawings may be seen and information obtained on application to Mr. James Deas, manager, Longford depôt, Warrington. Tenders to be sent to Mr. J. Deas, and are to be addressed to the chairman of the Sanitary Works Committee.

RESULTS OF TENDERS.

Southport.—The tender of Mr. J. Partington, of Chadderton, Oldham, has been accepted by the Town Council, at £1 420, for the erection of a chimney stack at the electric light station.

Bristol.—The following is the full list of tenders for installing the electric light at the Guildhall. Mr. F. Proctor is the electrical engineer :

F. W. Ball and Co. (accepted)	£438	18	0
Waring and Co.	440	0	0
Fowler, Lancaster, and Co.	444	0	0
Manchester Ediswan Company	444	2	6
Willway	463	0	0
Palmer	474	0	0
Baker, Newport	489	0	0
Curtis, Hanning, and Co.	500	0	0
Strode and Co.	517	0	0
Crompton and Co.	569	0	0
F. M. Newton	585	0	0
Cox-Walker	626	19	0
Pettit and Hards	645	15	6
Fergus and Co.	693	0	0
King, Mendham, and Co.	778	13	1
Newport Electrical Company	812	0	0
Roger Dawson	1,120	0	0

Edmonton.—A committee of the District Council have recommended the acceptance of the tender of the Consolidated Telephone Construction and Maintenance Company for fire alarms. Before doing this, however, enquiries are to be made of the Local Government Board and of the company with regard to variations of the estimates.

London.—The Metropolitan Asylums Board have accepted the tender of Messrs. F. C. and P. M. Benest, of 30, Cromwell-grove, West Kensington-park, W., to supply and fix overhead electrical fire-alarm wires and posts between the Darenth Schools, the farm buildings, and the Gore Farm Hospital, for the sum of £72; and to maintain in thorough working order, etc., for a period of three years, the whole of the electric bell system throughout the asylum, schools, and pavilions at Darenth for £75 per annum.

BUSINESS NOTES.

Aberdeen.—It is intended to light the infirmary by electricity.

Northwich.—A local electric lighting company, it is reported, is to be formed.

Crewe.—It is probable that the Mechanics' Institute will be lighted by electricity.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3 388.

Dundee.—A further sum of £10,000 is to be borrowed by the Town Council for electric lighting purposes.

St. Pancras.—The Electricity Committee of the Vestry have decided not to abolish meter rentals for the present.

Woking.—The Sanitary and Lighting Committee of the Council have recommended an addition to the number of electric lamps.

Brentwood.—A petition has been presented to the Lighting Inspectors suggesting the lighting of the parish roads by electricity.

Manchester.—The City Council on Wednesday decided to refer to a special committee the question of municipalising the tramways.

Keswick.—The Urban District Council have consented to the application by the local electric lighting company for a provisional order.

Devonshire.—The Lunacy Commissioners of the Devonshire County Council intend to spend £5,000 on the electric lighting of the county asylum.

Stockton-on-Tees.—The Electric Lighting Committee of the Town Council have deferred for six months the consideration of the electric lighting scheme.

Brush Electrical Engineering Company.—The debenture stock transfer books of the Brush Electrical Engineering Company, Limited, are closed from the present to March 2.

West India and Panama Telegraph Company.—For the two weeks ended February 15 the receipts show an increase of £201 as compared with the corresponding period of 1894.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 17th inst. amounted to £843, as compared with £671 in the corresponding week of last year.

Battersea, S.W.—The Vestry last week authorised the Electrical Committee to expend £200 in getting the opinion of experts as to the advisability of using electric light in the parish.

Finchley.—The District Council have instructed Messrs. Sax and Co. to do what is necessary in order to remove defects in the batteries used in connection with the fire brigade telephone service.

Change of Address.—The Magnetite Sewage and Water Purification Company have removed from 19, Bridgewater-chambers, 6, Brown-street, Manchester, to 33, Barton-arcade, Deansgate, Manchester.

Birmingham.—The Technical School Committee of the Town Council have decided to adhere to their recommendation, to which we referred two or three weeks ago, to introduce the electric light in the new technical school.

Southend.—A motion by Councillor Bowmaker for a special committee to consider and report upon the electric lighting of the borough has been carried by the Town Council. The mover said the present gas lighting was a disgrace to the town.

Scarborough.—The Town Council have had before them the subject of the new Gas Bill, in connection with which it was mentioned that there had been during the past year a slight decrease in the quantity of gas used in some streets owing to the electric light.

Electrograph Syndicate, Limited.—This Company has been registered, with a capital of £2,000, for the acquisition of certain English patents relating to a process for marking indelibly paper, fabrics, and other receptive materials, and to turn to account the same.

Dewsbury.—The Town Council have decided to charge a rental equal to 10 per cent on the prime cost for the hire of meters, and to allow discounts on all accounts for the supply of electricity at the same percentage and on the same conditions as in the case of the supply of gas.

Southampton.—Mr. Lamport intimated to the Town Council last week that he did not intend to proceed with a proposition of which he had given notice, that the electric light should be used in the Council-chamber and offices, on condition that the matter was referred to committee.

Alliance Meter Company, Limited.—This Company has been registered, with a capital of £5 000 in £1 shares, to carry into effect an agreement between John Clarke and W. Coward, and to conduct business as ironfounders, mechanical engineers, electrical engineers, gas producers and suppliers, etc.

Digitized by Google

Pilbarra Goldfields, Limited.—This Company has been registered to carry on mining business, and, among things, to construct and maintain rail and tram roads, canals, telegraphs, telephones, gas, electric, irrigation, and other works.

Vaughan and Brown, Limited.—This Company has been registered, with a capital of £40,000, to acquire the business of electrical, gas, hot-water, sanitary, and ventilating engineers and art-metal workers, as hitherto carried on at 15, 16, and 17, Kirby-street, Farringdon-road, E.C., under the style of Vaughan and Brown.

Norwegian Agency.—The Unbreakable Pulley and Mill Gearing Company, Limited, of Hyde-road Engineering Works, West Gorton, Manchester, inform us that they have appointed the Amerikanske Maskincompagni Tordenskjolds Plads, Christiania, as their sole agents for the sale of "Gorton" gas-engines for Norway.

City and South London Railway.—The receipts of the Company for the week ended February 17 were £998, against £938 for the corresponding week of 1894, or an increase of £60. The total receipts for the current period of the present half-year are £7,039, against £6,665 in the corresponding period of 1894, an increase of £374.

Hertford.—The Town Council at their last meeting received a report from the Lighting Committee which stated that they had received a tender from the Brush Electrical Engineering Company, Limited, for a complete electric light undertaking, but that this tender has not yet been considered by the committee. The report was agreed to.

Maidstone.—Alderman Long mentioned to the Urban District Council, at a meeting last week, that there was no report from the Electric Lighting Committee. They had a meeting the previous day, but it was not agreed whether the order should be disposed of or not. The committee hoped to make a recommendation to the next meeting of the Council.

Kensington.—The clerk to the Vestry has read a letter from the Board of Trade transmitting copy of a draft provisional order granting to the Notting Hill Electric Lighting Company an extension of their present area of supply under the Notting Hill Electric Lighting Order, 1889, and asking that any observations the Vestry may desire to make thereon may be forwarded at the earliest possible moment.

Post-Office Lighting.—Messrs. W. Curtis and Sons, of 98 and 99, Abbey-street, Dublin, inform us that they have secured the contract for the electric lighting of the Accountant's Department, General Post Office, Dublin. The total number of lamps provided for will be 110, and the work is to be carried out from the designs and under the directions of Mr. J. Howard Pentland, senior surveyor to H.M. Board of Works in Ireland.

Engineer Required.—The services are desired of an engineer, who must be a member of the Institute of Mechanical Engineers and Institute of Civil Engineers, and have had considerable experience in hydraulic, electric lighting, and other machinery, and also in the building of steam tugs, iron barges, etc. Applications are to be sent, by letter in the first instance, stating salary and full particulars, to Wm. Cory and Son, 52, Mark-lane, London.

St. James's, S.W.—The Vestry have resolved on the motion of Mr. Angold, "That it be referred to the Lighting Committee to consider and report (*a*) as to the desirability of lighting the main thoroughfares of the parish, such as Regent-street, Piccadilly, St. James's-street, and Pall-mall, with electric light; (*b*) the best system of electric lighting for such thoroughfares; (*c*) the estimated cost as compared with gas; and (*d*) generally upon the whole question."

Morecambe.—The Sanitary Committee of the District Council have reported that they have received a letter from Mr. J. Imbrie complaining of nuisance at the works of the Morecambe Electric Light and Power Company, Limited, in Edward-street and Union-street. It was resolved, on the motion of Messrs. Lee and Carter, that the matter be referred to the medical officer of health for his report, and that after receiving the same a meeting of the committee be called for directions.

Worcester.—A deputation from the City Council has waited upon the Board of Guardians to invite their adoption of the electric light in the new workhouse buildings. Mr. W. Morris moved that the Building Committee be instructed to enquire into and report to a special meeting on the question. This was agreed to by 23 votes to 5. The directors of the Worcester Theatre Royal have decided to have the auditorium illuminated by the electric light. The lamps will number upwards of 70.

Ship Ventilation.—A new system of improved ship ventilation has recently been introduced by Messrs. Baird, Thompson, and Co., Limited, ventilating engineers, of London and Glasgow. The method has been subjected to severe tests, and has proved very successful. One of the principal Atlantic steamship lines, after trying it on one of their vessels, have already adopted it for the whole of their fleet. It is claimed for the Baird-Thompson system that it is most efficient, economical, and reliable.

Bowness.—The chairman of the Urban District Council recently informed the Council that the manager of the electric light company had been seen, and he had informed them that they were about to put in a new cable. The defect in the light hitherto had been owing to the fact that the existing cable was too weak. The charge to the Council would now be 25 per cent. less than that made to ordinary customers, which was now 10d. per unit. The committee proposed that a meter should be put on the circuit.

New Swindon.—Mr. Batt, at a recent meeting of the Urban District Council, moved the adoption of the Electric Lighting Committee's report, which stated that the committee had fully considered the electrical engineer's report, and also the report of the former Electric Lighting Committee appointed by the late Board, and they considered that the application for a provisional order should be proceeded with. Mr. Protheroe proposed, and Mr. Pryce seconded, the adoption of the report, which was adopted.

Copper.—Copper stocks continue to accumulate, the increase in the first half of this month being 866 tons, and the visible supply is greater than at any time in the past two years. The arrivals from America were considerably smaller than in the corresponding half of January; indeed, it is not because of growing imports, but of diminishing consumption that stocks are increasing. In the first half of January 5,742 tons were delivered, against only 4,206 tons to the 16th of this month; so that the recent spurt in consumption seems to have exhausted itself.

Brighton.—The chairman of the Brighton Grand Hotel Company, Limited, mentioned, at a meeting of the company on Wednesday, that since August last the supply of the electric light in the building had been obtained from the Brighton Corporation, and that so far a total saving of £505 had been effected under this head. Every effort would be made, he stated, to dispose of the private installation plant on favourable terms, and there was reason to believe that the loss in this respect would not be so heavy as was at one time expected.

Blackpool.—In the minutes of the Electric Lighting Committee of the Town Council presented to the latter recently it was recommended that Mr. R. Hammond, consulting engineer, be desired to confer with Major Cardew, the electrical adviser of the Board of Trade, as to a proposed variation of the system by means of which electrical energy is to be supplied by the Corporation. A committee was appointed to confer with and direct the borough surveyor upon the subject of the laying of the electric centre channel of the tramways in Lytham-road.

Yarmouth.—The Corporation have received orders for 2,468 lamps, of which 1,181 have been wired and connected and at work, whilst the others are being rapidly connected up. The plant laid down provides for 4,500 lamps of 8 c.p. Leads have been ordered to be laid down Jetty-road at a cost of £20 to supply customers. Messrs. Crompton's tender to supply carbons at £8. 17s. per 1,000 pairs for one year has been accepted. Permission has been given to Messrs. Palmer Bros. to fix seven electric lamps with shades in front of their establishment.

Portsmouth.—The Portsmouth Electric Lighting Committee have just issued their balance-sheet showing the result of the first half-year's working. It shows an actual working profit of £1,514. 9s. 3d., which, had the undertaking been a private concern, would have provided a 6 per cent. dividend for the shareholders. Being a Corporation concern, however, the money borrowed on capital has to be repaid in a certain number of years, together with the interest, and the amount due for the six months was £1,640. 19s. Thus there was an apparent loss to the public of £126. 9s. 9d.

Douglas (Isle of Man).—The Town Commissioners decided on Wednesday upon the construction of a system of tramways to Upper Douglas, and to grant the use of such tramways to a company that may be formed to work the same for a period of 21 years, the use for the first four years to be free of cost to the company, who in the next 16 years are to pay the Commissioners interest and sinking fund upon the capital expenditure, provided that a satisfactory guarantee is given by the company for the proper working of the lines for the period named, and the repayment of the principal and interest.

Warminster.—The Urban District Council have met, and the chairman, Mr. W. F. Morgan, moved that the Council should apply to the Board of Trade for a license authorising them to produce electric light for public lighting, but on the clerk explaining that a license would cost £100, the Chairman asked for permission to withdraw the proposal till the Board was in a position to undertake the production of the electric light, when it was hoped the money required for carrying it out would be provided out of the current rate, and thereby remove the necessity of obtaining a Board of Trade license.

Radcliffe.—The District Council have held a meeting, at which Mr. Cunliffe, before the Streets Committee's minutes were confirmed, asked if the electric lighting work of the late Local Board had been taken cognisance of. They were under certain obligations in regard to the work, and he understood the Electric Lighting Committee had been merged into the Main Roads and Lighting Committee. The Clerk said there was no special committee for dealing with the electric light question, and he brought it before the Main Roads Committee, as they had to deal with the question of lighting the streets. The minutes were confirmed.

Leeds Tramways.—The Corporation in their Bill before Parliament seek to revise the powers granted to them by the Leeds Corporation Tramways Order, 1888. They ask for power to make a new tramway from the junction of Kirkgate and Call-lane, through York-street, and terminating in Marsh-lane by a junction with the existing line; also one along Burmantofts-street and Beckett-street. The Bill further seeks power to construct stations for generating electrical power for the purpose of working the existing and intended tramways on the sites of the destructors at Wortley and Meanwood-road, and at the sanitary depôt in the Calls.

Hampstead.—The Vestry have received from private consumers £42. 9s. 1d. for electric current and meter rent to December 31. The Lighting Committee have recommended that Messrs. Siemens Bros. and Co. should be asked to keep in stock a mile of each kind of cable for use in future extensions in this parish. The committee are in communication with the Willesden

Digitized by Google

District Council on the subject of lighting the High-road, Kilburn, with electric light. The engineer is to prepare a specification for the installation of electric light to the town clock, and Messrs. Verity and Sons, F. Taylor, and W. Thompson have been invited to tender for the same.

Fire Brigade Telephones.—The Fire Brigade Committee of the London County Council on Tuesday reported that they had ascertained that the annual charge for telephonic communication between the street station to be located in Baggallay-street, Mile End, and the nearest fire-engine station will be about £12. 10s. On the establishment of the street station the fire-alarm in Burdett road, for which an annual rent of £7. 15s. is paid, will be dispensed with, and the increased annual cost will therefore be less than £5. They consequently recommended that the street station in Baggallay-street be placed in telephonic communication with the Mile End station.

Arlecdon.—A meeting has been held of the Arlecdon and Frizington Urban District Council, at which Mr. Richards moved that the Board secure the services of a thoroughly practical engineer to come and examine the district and the various watercourses which may be available, and ascertain whether sufficient motive power could be produced by these to light the district with electricity; and that he report on the cost of a scheme for lighting the district by electricity, whether with water power or steam power. The motion was agreed to, and it was agreed that Mr. Kirkbride, Father Hurley, and Mr. Richard should be a committee to consult with Mr. Brodie, the engineer for the Corporation of Whitehaven.

Planet Electrical Engineering Company.—Mr. Hamilton moved before Mr. Justice Stirling on Friday for the appointment of Mr. Claud Scott, secretary of the above Company, as receiver and manager. The plaintiffs were holders of £2,500 debentures of the Company, issued on the usual term that principal becomes due and payable upon default of payment of interest. The debentures were issued in 1893, the interest was payable half-yearly, and no interest had yet been paid. Mr. Sheldon appeared for the Company, and consented to the application. His Lordship thereupon appointed Mr. Scott, but directed that he should not act as manager longer than six weeks without leave of the judge in chambers.

Appointments Vacant.—The Aberdeen Town Council invite applications for the position of electrical engineer. The remuneration offered is £200 per annum, and applications are to reach the Town Clerk not later than Monday next. The person appointed will be required to take charge of the electric lighting department under the superintendent of the Corporation gasworks, act as executive engineer at the station, and devote his whole time to the duties of the appointment.—The Corporation of Cardiff require an electrical engineer to take charge of the central station at a remuneration of £200 per annum. Mr. W. Harpur, the borough engineer, Town Hall, Cardiff, will give any further information on the subject. Applications are to be sent in not later than March 7.

Foyers (Scotland).—The Procurator-Fiscal for the county of Inverness has been asked to furnish a report on the proposed works to be erected at Foyers by the British Aluminium Company. The company have entered into contracts with the proprietors in the district for the acquirement of extensive lands and water rights, and Mr. Charles Innes, solicitor, Inverness, who is representing the company in the North, has been in the Foyers district carrying out the necessary negotiations. Captain Charles Ross, of Balnagowan, who is proprietor of an estate on the banks of the Clyde, has, it is stated, been offered £3,000 per annum for his water rights in the neighbourhood of the famous falls, so that the water might be used for a similar purpose—viz., the production of electricity.

Telephone Cable on Hammersmith Bridge.—A committee of the London County Council have reported that they have had under consideration an application from the National Telephone Company for permission to run a telephone cable between two poles on the east side of Hammersmith Bridge, and they recommended that the application be granted, subject to the payment by the company of a rent of £10 per annum, to the cable being laid and the work being executed to the satisfaction of the chief engineer of the Council, to the company making good at its own sole cost any damage that may be done to the bridge or its approaches in carrying out the work, and to remove the cable on receiving a month's notice from the Council, and that the foregoing conditions be embodied in an agreement to be prepared by the solicitor of the Council.

Whitehaven.—The Town Council have adopted the minutes of the Water and Lighting Committee, which stated that Mr. Brodie had reported that the cost of putting in the electric light at the harbour clock would be £10 and the cost of maintenance and lighting £20 per annum. It was resolved that the surveyor should submit the estimate to the Harbour Commissioners. A letter has been read from Messrs. Siemens Bros. and Co. asking the Corporation to do electric lighting repairs necessary under their contract, and charge them with the cost. The engineer has read to the committee correspondence which has passed between Dr. Hopkinson and himself in reference to additional engines contracted to be supplied by Messrs. Willans and Robinson. The Markets and Buildings Committee have postponed a report on the cost of fitting the Town Hall with the electric light.

Newcastle Contracts.—Messrs. Rowland, Barnett, and Co., Limited, of 8, Mosley-street, Newcastle-on-Tyne, who carried out a small installation at the Silksworth branch of the Ryhope and Silksworth Co-operative Society about two years ago, have been instructed to supply and erect a complete installation at the headquarters, Ryhope. The plant will consist of a 28-kilowatt compound dynamo, about 270 incandescent lamps, and two series arc lamps. This firm are also equipping an electric light plant for the new Catholic church, Felling, consisting of a 12-b.h.p. Tangye gas-engine, one 6½-kilowatt dynamo, a battery of 55 secondary cells, and about 50 lights of from 8 c.p. to 100 c.p. In addition to the above they have on order from the New Olympia, Limited, Newcastle, one 16-kilowatt compound dynamo, switchboards, etc., and 170 16-c p. and three 200-c.p. incandescent lights, and two series arc lamps.

Edinburgh.—At a meeting this week of the Town Council, Mr. Douglas asked what provision was being made to ventilate the electric light mains with the view to prevent gas accumulating. Mr. Mackenzie said that the road boxes were quite necessary, and that there was a large leakage of gas going on continually It had been alleged that electrolysis took place in the conduits, and that the gas thus formed was what caused the explosion, and not coal gas. It had not been proved that one single explosion had taken place in this country through this cause, and only in a few cases had the gas mixture been fired by electric mains sparking. The electric light department were quite alive to the danger, and were taking the best steps they could think of to guard against it. There was to be a conference between representatives from the Gas Commission and representatives of the Electric Light Committee to try and arrive at some common understanding.

Dublin.—A most important notice was read at the last meeting of the Dalkey Commissioners from Mr. Clifford Robinson, C.E., managing director of the Southern District Tramway Company, informing them that the electric railway between Dalkey and Dublin would be commenced at once. It had been decided to begin making the line on February 1, but owing to the severe frost it was found impossible to break up the roads. It is hoped that by March 1 the weather will have so far improved as to permit of operations being commenced. The Dalkey Commissioners do not intend interfering with the proposed arrangement of having the electric wires overhead, which is considered more convenient than carrying them underground. The directors of the Dublin United Tramways Company, after a careful inspection of the leading systems on the Continent, have called in Mr. Robert Hammond, of London, to report to them as to the best means of applying electric traction to their undertaking in Dublin.

Huddersfield.—Attention was drawn by Mr. Oxley at a meeting of the Town Council on Wednesday to a statement in the minutes of the Electric Lighting Committee that there was a deficiency on the revenue account for the year ended December 31 last of £2,065 4s. 9d, and that the Finance Committee should be asked to provide for the deficiency. As the representative of an outdistrict which had had to pay 3s 3d per 1,000ft. for its gas, whereas the central parts of the borough paid 2s 9d, he strongly objected to that district being called upon to help to pay for the deficit on electric lighting when they received no benefit from the electric light. He moved that the subject be referred to the committee. Mr. Broadbent seconded this. Mr. Calvert, chairman of the committee, said the interest and sinking fund on the works amounted to nearly £3,400. If they had been a private company instead of a corporation they would have made a profit of £1,400. As they had to repay their money in 15 years, they had to pay an abnormal amount to the sinking fund. In 15 years' time, with the present output, they would be able to make a profit of £3,000 a year. The motion was withdrawn, and the recommendation of the committee was adopted.

Telephone Tubes in the City.—On Tuesday a meeting of the City Commission of Sewers was held, when Mr. Johnson asked whether any progress had been made with regard to negotiations between the Court and the companies on the question of the use of the telephone tubes, in return for which concession the ratepayers were promised a revenue of £1,000 or £2,000 a year. Mr. Berridge said the matter would be discussed at the next meeting of the committee Mr. Barham warned the Commission that it must be very careful lest it lost the opportunity of securing to telephone users a cheaper rate than they were at present forced to pay. Mr. Johnson declared that the Commission was engaged in a most visionary pursuit in supposing that it was going to secure a reduction in the cost of the use of telephones. What the Commission had to do was to look after the interests of the ratepayers and take something in exchange from the companies which would benefit the payers of taxes The members of the Commission were appointed to watch the interests of the ratepayers, and not to study those of telephone users. The Chairman reminded the meeting that there was really nothing whatever before it on the subject which had been discussed. The matter then dropped.

Ealing.—It was reported to the District Council last week that through certain circumstances, including the illness of Mr. Harris, the engineers (Messrs Bramwell and Harris) had been unable to furnish the Council with a detailed statement of the expenditure in connection with the electric light installation, but that they hoped to be able to place that statement before the Council at the next meeting. The clerk stated that he had written to the Local Government Board requesting them to reconsider their decision not to sanction the issue of stock by the Ealing Local Board, and also asking the Board above to allow the issue of stock by that Council, but had received no reply to his communication. Mr. Baker Haye urged that the Council must, for financial reasons, promptly take some definite steps to raise, either by the issue of stock or otherwise, the sum (£25,000) authorised to be borrowed for electric lighting purposes, and any further sum which it might be found would be needed as a consequence of the extended electrical installations. The clerk was directed to again write to the

Digitized by Google

Local Government Board, impressing upon them the necessity for an immediate reply to the question whether they would be prepared to reconsider the decision at which they arrived with respect to the application of the Board, and would be prepared to entertain an application by that Council for an issue of stock.

Telegraph Construction and Maintenance Company.—The report of the directors for the past year states that the accounts show a net profit of £91,921, after charging the interest on the debentures. To this sum must be added £51,228 brought forward from last year, making a total of £143,149. From this amount is deducted the interim dividend of 5 per cent., paid July 24 1894, amounting to £22,410, leaving £120,739 to be dealt with. Of this sum the directors propose to distribute a dividend of £1. 16s. per share, being at the rate of 15 per cent., and making, with the amount already paid, a total dividend for the year of £2. 8s. per share, or 20 per cent., free of income tax, leaving £53,509 to be carried forward to the next account. The operations carried out during the year comprise the laying of a cable for the Eastern Extension Telegraph Company between Singapore, Labuan, and Hong Kong, and the manufacture of a cable for the Anglo-American Telegraph Company and its laying between Valentia and Newfoundland. Several lengths of cables have also been manufactured for different telegraph administrations and companies. Repairs of cables have been carried out in the North Sea and English Channel for the German Government. The transfer books are closed until the 26th inst, preparatory to the payment of dividend to all shareholders on the register on the 18th inst.

Underground Telephone Conductors.—The Highways Committee of the London County Council reported to that body last week as follows: "The Council on 19th June last gave permission to the National Telephone Company to construct a lateral passage from the Shaftesbury-avenue subway, at Macclesfield-street, for the purpose of conducting pipes from the subway to the new exchange station in Gerard-street, such permission being, however, subject to the following conditions: that the work shall be carried out in accordance with the plan submitted with the letter, dated 15th March, 1894, from the company's metropolitan manager, and under the supervision and to the satisfaction of the Council's chief engineer; that any damage that may be done in or about the subway during the execution of the work shall be made good by the company to the engineer's satisfaction; that the company do pay to the Council a rent of £50 a year for the accommodation, and do also provide, free of charge, additional direct connections between the exchange station and such two of the Council's offices as may hereafter be determined; and that the company do enter into an agreement to be prepared by the Council's solicitor, embodying the above conditions. This agreement has been prepared, and we recommend that the seal of the Council be affixed to the agreement above referred to with the National Telephone Company."

Southport.—The Works and Plan Sub Committee have reported to the Town Council that they had received a letter from Prof. Kennedy, in which he stated that the committee would be wise to extend the buildings on the general lines shown on the plan prepared by the borough surveyor. Councillor Hesford, in moving the adoption of the minutes, said that, on the advice of their engineer, an extended test had had to be abandoned Referring to the acceptance of a certain tender for the erection of a new chimney at Crowlands, he remarked that they had had the ground bored, so that for the distance of upwards of 20ft. they knew exactly what the substratum of the soil was. One hundred pitch-pine piles of 25ft. long and 12in. in diameter would be used Concrete would be added, and from this would be a superstructure of 192ft. Really, however, the chimney would be 130ft. They had received 13 tenders for the work, and the one accepted they asked the Council to pass that night. For the carrying out of the extensions to the boiler and engine house they had 18 tenders, which, after having been opened by the committee, were considered by a sub-committee, and they had made a careful selection. Councillor Todd seconded. After some discussion, the minutes were adopted, with the exception of that referring to the tender for boiler and engine house extensions, which was referred to the General Purposes Committee.

Lambeth, S.E.—A special meeting of the Vestry was held on Thursday of last week to consider the electric lighting question. Mr. John Williams submitted a motion requesting the Vestry to surrender the electric lighting order. The present position of the question was this: that they would have to "clear out" of the lighting order and let others come in, if they cared to do so, or go on with the scheme themselves. He was sure the Vestry did not want to take up the attitude of the "dog in the manger," and it was their duty if they could not see their way to adopt the electric light to stand aside and allow others to do so. Mr. Quick, who seconded, contended that the ratepayers had nothing to gain by allowing their Vestry to go in for any trading concern. The Vestry next received a deputation from the Lambeth Ratepayers' Association against the proposed scheme. A letter was received from Mr. S. Morse, on behalf of the County of London and Brush Provincial Electric Lighting Company, offering to take over the provisional order. The clerk (Mr. H. J. Smith) said Mr. Morse had called upon him, and had told him that his company intended to commence at once, and were perfectly ready to take over the Lambeth order, and to repay the Vestry the amount they expended in obtaining it. Mr. Akerman moved, as an amendment, that the Vestry proceed to the next business. This having been seconded, was put to the meeting and carried.

Coventry.—The Electric Light Committee of the Town Council have presented the following report: "According to the contract for the equipment of the electric lighting works, the supply mains are laid only on the east side of the street in Burges, Cross-cheaping, and Broadgate. This involves the trouble and expense of crossing the tramway line whenever it is necessary to connect a consumer on the west side. Your committee recommend that to avoid this a second supply main be laid on the west side of these streets, at the estimated cost of £203 5s. 9d. Your committee also recommend that a wall be built along the canal wharf at the works to enable coal to be stored there, at a cost not exceeding £30." The committee recommended in their minutes that the Liberal Club, distant 52 yards from the nearest main, be supplied with the electric light on the same terms as consumers within the 50 yards limit. Alderman Hill moved the adoption of the report, and said the recommendation about the new main was a question of economy. It would cost less to take the cable up the street than to be frequently running under the tram line. There was an estimate for carrying the cable to the bottom of Hertford-street in the same position, and possibly action might be taken on that, but at present the committee did not recommend it. Mr. West seconded the adoption of the report, saying it was the opinion of the engineer that if there were many installations of the light on the west side of Broadgate it would be cheaper to put a main in than to go on the alternate plan. The report was put to the meeting and adopted.

Windsor.—The Town Council had before them last week a motion by Mr. Dyson to the effect that steps should be taken to ascertain what amount of water power could be obtained from the Thames for the production of the electric light and electricity as a motive power. With papers before him he proceeded to argue the question that motive power could be obtained from the river for the supply of electricity, when Mr. Lovegrove pointed out that the Council had no power over the Thames, and Mr. Dewe asked what was the use of going into the question, having already taken the opinion of Mr. Shoolbred, their consulting engineer. Mr. Dyson replied that he presumed the Thames Conservancy were approachable, and if it was capable of being done surely the Council would not reject it merely because one gentleman had said it could not be done, because it had been done in other places. Mr. Bampfylde suggested that these matters could very well be brought before the committee, who could thrash out the question and bring something before the Council. Mr. Dyson replied that it was no use going before the Electric Lighting Committee because they had made up their minds, but he had certain facts he could lay before the Council. Mr. Soundy said if they were laid before the Electric Light Committee he would guarantee that they would be carefully considered. Mr. Dyson said he would accept the suggestion, and accordingly, on the motion of Mr. Soundy, seconded by Mr. Caley, the question of obtaining water power for the production of electricity was referred to the Electric Light Committee to consider and report.

Cardiff.—A meeting of the Court of Governors of the University College of South Wales and Monmouthshire has been held at the College, Cardiff, the Right Hon. Lord Aberdare being in the chair. Principal Jones informed the court that in the new engineering department great progress had been made, and two-thirds of the work were now completed. A testing-house and large workshop had been erected, but the boiler-house remained to be done. They were unable to proceed with this until the chemical laboratory was removed from the site over which the house was to extend. Greatly increased accommodation in the chemical laboratory would be required in the immediate future. The boiler was in place, a Willans steam-engine of from 35 h.p. to 40 h.p. had been erected, and this would drive the dynamo for the purpose of lighting the shops, and also the motor for the testing-house. The testing machine was the property of the Technical Instruction Committee, and had been purchased at a cost of £2,000. On Tuesday a meeting of the Lighting and Electrical Committee of the Cardiff Corporation was held, when the town clerk read a letter from Principal Viriamu Jones stating that the Technical Instruction Committee had appointed a deputation to wait on the Lighting Committee to lay before them the following points: (1) the feasibility of the utilisation of the new electrical works for the training of electrical engineers; (2) the advisability of the establishment of an electrical laboratory for the standardising of all electrical measuring instruments that may be in the town; and (3) the question of the improvement of the lighting outside the Stacey-road Hall. Alderman Jacobs asked how it was proposed to send the students. Principal Jones replied that it might be that from time to time the teacher would go to the officers and ask to be allowed to take in a class to see a certain thing; but what they chiefly desired was that the Corporation should make arrangements by which they could take in well-qualified students as apprentices for, say, three months at a time The borough engineer was instructed to report regarding the lighting at Stacey-road Hall, and it was decided to postpone consideration of the other matters until Councillor T. H. Riches was able to be present.

PROVISIONAL PATENTS, 1895.

FEBRUARY 11.

2965. **An improved process for the electro-deposition of aluminium and aluminium alloys.** Alfred Francis Bilderbeck Gomess, 9, Warwick-court, Gray's-inn, London.

2969. **Portable electric alarm attachable to either lever or pendulum clock or timepiece.** William Gardiner Grossett, 49, Dongola-road, Plaistow, London.

Digitized by Google

2971. **Improvements in electrically-heated curling-irons.** Alfred William Armstrong, 85, Broadhurst-gardens, West Hampstead, London.

2998. **Improvements in and apparatus for the manufacture of copper, zinc, and other metal sheets, strips, or wires electrically.** The Cowper-Coles Galvanising Syndicate, Limited, and Sherard Osborn Cowper-Coles, 47, Lincoln's-inn-fields, London.

2999. **Improvements in and means to be employed for the obtainment of zinc from its ores, and the electro-deposition of zinc upon iron or other metals or alloys.** The Cowper-Coles Galvanising Syndicate, Limited, and Sherard Osborn Cowper-Coles, 47, Lincoln's-inn-fields, London.

3000. **Improvements in secondary batteries.** Camille Alphonse Faure, 47, Lincoln's-inn-fields, London.

3002. **Improvements in electric arc lamps for photographic purposes.** George Devey, 46, Lincoln's-inn-fields, London.

3003. **Improvements relating to the regulation of electric motors.** William Phillips Thompson, 31, High Holborn, London. (Emile Lauhoffer, Arthur Burghardt, and Jacques Burghardt, Germany.)

3006. **Improvements in electric arc lamps.** William Ernest Burnand, Norfolk House, Norfolk-street, London.

FEBRUARY 12.

3055. **Improvements in or connected with electric steering apparatus.** Frank King, 47, Lincoln's-inn-fields, London.

3062. **Improvements in electric locomotives.** Eben Moody Boynton, 52, Chancery-lane, London. (Complete specification.)

3066. **Improvements in means for preventing the liquid of primary and secondary batteries being spilt and for rendering it motionless, more especially during transport.** Edouard Henriquez, 70, Palace-chambers, Westminster.

3067. **Improvements in electrical storage batteries.** Edouard Henriquez, 70, Palace-chambers, Westminster.

3076. **Improved combined telephone and telegraph systems.** Henry Harris Lake, 45, Southampton buildings, Chancery-lane, London. (Christopher A. Shea and Freeborn Fairfield Raymond, United States.)

3081. **An improved ventilating-box cover for electric lighting culverts, or ways, sewers, cellars, or other places needing ventilation.** Albert Essinger and William Parrott, 26, Thavies-inn, Holborn, London.

3085. **Improvements in and relating to electric gas-lighting devices.** Jean Jahnsson, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

3086. **Improvements in automatic telegraph machines.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (World Flash Company, United States.) (Complete specification.)

3087. **An improved telephone system.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Christopher A. Shea and Freeborn Fairfield Raymond, United States.)

3095. **Improvements in and relating to electrical exchange systems.** George William Hey and Arthur Edward Parsons, 11, Southampton-buildings, Chancery-lane, London.

FEBRUARY 13.

3125. **Improvements in brackets for gas, oil, or electric light.** Charles Meason and Thomas Ford, St. Ives, Crompton-road, Handsworth, Birmingham.

3134. **Improvements in apparatus for indicating or recording telephonic connections.** Friedrich Wilhelm Heinrich Hempel and Alfred Maerker, 62, St. Vincent-street, Glasgow. (Complete specification.)

3172. **A method of ventilating the pipes, manholes, chambers, etc., containing the wires conveying electricity through streets and public ways.** Arthur Coke, 339, Oxford-street, London.

3178. **Improvements in and connected with testing and junction boxes, manholes, and culverts for electric light mains and other purposes and in the covers therefor.** William Macpherson, 11, Furnival-street, Holborn, London.

3179. **Improvements relating to electric light fittings.** Joseph Monteith, 6, Bream's-buildings, Chancery-lane, London.

3183. **Process for the production of concentrated sulphuric acid by means of electrolysis.** Leonhard Wacker, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

FEBRUARY 14.

3226. **An apparatus for steering steamships and other vessels automatically by the aid of electricity and the mariner's compass.** Frederick Edward Adams, 104, Park-road, Bolton.

3228. **Improvements in the ventilation and combined electrical and chemical purification of the atmosphere in open and closed spaces.** John Frick, 53, Chancery-lane, London.

3233. **A combination electric lamp and battery.** Thomas Edward Walter, 10, Basinghall-street, London.

3250. **Improvements in globes for electric glow lamps.** Victor de Spruner-Mertz and Joseph Koch, 28, Southampton-buildings, Chancery-lane, London.

FEBRUARY 15.

3331. **Improvements in or relating to electric arc lamps.** Frederic William Dickinson, 323, High Holborn, London.

3336. **Improvements in or connected with apparatus for electrically lighting miners' safety lamps.** William Ackroyd, William Best, and John Peel, 33, Chancery-lane, London.

3358. **Improvements in electric railway systems.** Malone Wheless, 47, Lincoln's-inn-fields, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, 3rd December, 1894, being date of application in United States.) (Complete specification.)

FEBRUARY 16.

3386. **Improvements in electrical indicators applicable for various purposes.** Edwyn Grahame, 10, Basinghall-street, London.

SPECIFICATIONS PUBLISHED.

1893.

24274. **Electrolytic decomposition of metallic salts.** Kellner. (Reprints, with alterations.)

1894.

1491. **Arc lamps.** Barton. (Jandus.)

2274. **Supplying electricity to tramcars, vehicles, etc.** Pringle.

3079. **Electric bell indicator.** Sanders.

5647. **Secondary coils for transformers.** Schneller and Wisse.

5913. **Alternating-current generators.** Raworth.

6089. **Protecting electrical conductors.** Kingdon.

6912. **Electrical accumulators.** Hagen and Beyer.

9456. **Junction or fuse box for electric wires.** Russell.

13995. **Electric railways.** Thompson. (McLaughlin.) (Second edition.)

21127. **Arc lamps.** Day. (Schoeffel.)

25080. **Separating metals by electric action.** Oliver.

NOTES.

New Book.—Mr. John Murray will shortly publish the second volume of Dr. Werner von Siemens's papers and addresses on scientific subjects.

Portable Lamps.—Portable electric lamps, it is reported, have been provided for the use of the bellringers at St. Edmund's Church, Salisbury.

Society of Arts.—On Tuesday next, at 8 p.m., a paper on "Colonies and Treaties," by Sir Charles M. Kennedy, K.C.M.G., C.B., will be read.

Definition of Reactance.—Mr. G. Giorgi has sent us a pamphlet on this subject, being an abstract of a contribution which appeared recently in *L'Elettricista*.

Electric Railway Bills.—The City and South London and the Great Northern Railway Bills were read a second time in the House of Commons on Monday.

Nice Electric Tramway.—A trial trip has been made on the electric tramway which has been constructed from Nice to Cimiez, and to which we have already referred.

Railway Rates.—The Board of Trade has extended for three months from the 22nd ult. the period within which complaints may be made regarding railway rates.

Electric Motors for Tree-felling.—According to the *Chronique Industrielle*, augers driven by small electric motors are being used in the forests of Galicia in connection with the felling of trees.

Electric Tramways in Europe.—Our contemporary *L'Industrie Electrique* has in course of preparation the third issue of its statistics of electric tramways and railways in operation on January 1, 1895.

Burmo-China Telegraph.—It is reported by the *Indian Engineer* that Mr. Jensen was to have completed his work at Momein in connection with the Burmo-China telegraph by the end of January.

Exhibition at Geneva.—There is to be held in Geneva next year an industrial exhibition in which a large section will be devoted to the applications of electricity. The exhibition will not be of an international nature.

Specialities for Watchmakers and Jewellers.—Messrs. Koch and Co., of Charterhouse-buildings, E.C., have forwarded us a copy of a catalogue illustrating the "Triumph" lathe and other specialities for watchmakers, jewellers, and opticians.

Economy.—Notwithstanding the fact that the inhabitants of Cardiff have been somewhat tardy in adopting the electric light, it is satisfactory to find that already some of those who have had their premises wired have found that electric light is cheaper than gas.

Students of the Institution.—A students' meeting of the Institution of Electrical Engineers will be held in the library of the Institution, 28, Victoria-street, on Friday next, the 8th inst., at 8 p.m. A paper on "Incandescent Lamp Manufacture," by Mr. Leonard Johnson, will be read.

Forthcoming Lecture.—A lecture on "Recent Developments in Electrical Science" will be delivered on Monday next, the 4th inst., by Mr. Fred H. Taylor, A.I.E.E., at the St. Andrew's Parish Room, Fairholt-road, Stoke Newington, N. The lecture will commence at 8 p.m.

Society of Engineers.—The next ordinary meeting of this society will be held at the Westminster Palace Hotel on Monday next, when a paper will be read on "Parliament Procedure as affecting Light Railways and Tramways," by Messrs. W. Worby Beaumont and Stephen Sellon.

Indian Telegraphs.—Very satisfactory progress is reported in the annual budget of the Indian Telegraph Department. It now shows signs of being more satisfactory than was anticipated. A new telegraph cable is to be laid between India and Ceylon in March, the old one which was put down in 1865 being abandoned.

Award.—The Bernhard Prize Commission of the French Chambre Syndicale des Industries Electriques have awarded the prize to M. Genet, who is employed by the Société Industrielle des Téléphones, whose works are situated in Rue du Théâtre, Paris. The *Bulletin International de l'Electricité*, from which this item is abstracted, does not mention the object of the award.

Personal.—Dr. Warburg, of the Freiburg (Baden) University, has been appointed professor in experimental physics at the Berlin University, in place of the late Dr. Kundt.—Mr. M. G. Ross having resigned his position as managing engineer to the Hastings and St. Leonards-on-Sea Electric Light Company, Mr. Leonard Andrews (who has had the charge of running the station for the past 16 months) has been appointed to take over his duties.

Douglas-Laxey Extension Line.—The late snowstorm has hindered the construction of the new railway from Laxey to Snaefell Mountain. Now, however, a numerous gang of men is engaged on the work, and the directors are endeavouring, if possible, to have the railway open for the summer visiting traffic. The line is to be worked on the overhead electric system, the same as on the present Douglas and Laxey electric tramway, in conjunction with which it will be run.

Indian Telegraph Department.—It is said that the mountain line of telegraph between Gilgit and Srinugger is undergoing a severe ordeal this winter, which has proved to be a keen one in Cashmere, being marked by tremendous snowstorms, which have at times lasted six days on end. The wire, the *Indian Engineer* states, has broken in several places, but the two repairing parties stationed between the Burzil and Traghal Passes sally out and do the necessary repairs whenever an opportunity offers.

Protection Against Lightning.—The Admiralty direct that in order that men working under a ship in dry dock may be secure against danger by lightning, a thorough metallic connection by wire rope, or otherwise, is to be effected between several points of the ship's iron, such as ring bolts, etc., and iron pipes leading to the water outside the dry dock, there being no danger to anyone or anything inside the ship. Similar precautions are to be taken in respect to the frames of ships on the stocks in the course of building.

Telephone Exchanges.—Mr. A. Morley, replying to Sir C. Cameron in the House of Commons on Friday, said that he had consulted the solicitor to the Post Office, and that he was advised by him that even if a corporation obtained the Postmaster-General's license to transmit telegrams by telephone, it could not erect and maintain telephonic apparatus and manage what was generally understood by exchange business at the expense or risk of the corporate funds or rates, without the express sanction of Parliament.

Portable Electric Light Plant.—A description is given in *L'Electricien* of February 23 of the portable plant now being introduced by the Maison Bréguet. The plant, briefly, comprises a vertical boiler, a Laval steam-turbine, and a Manchester type of dynamo, the combination being intended for the use of the army for search-light purposes. The boiler is constructed on the Trépardoux system, the use of which is claimed to allow of the rapid raising of

Digitized by Google

pressure and of dry steam. The turbine and dynamo are coupled direct, and run at a high rate of speed.

Water Power in Scotland.—The attention of Sir George Trevelyan has been drawn to a project for utilising the famous Falls of Foyers, near Loch Ness, by using the water power to drive machinery for the generation of electrical energy. The project, as stated in our "Business Notes" last week, is entertained by a company which is about to start works for the extraction of aluminium. Sir George Trevelyan has instructed the local procurator-fiscal to enquire into the matter. It is proposed to bring the material from Ireland for the production of aluminium.

Telegraphy in Western Australia.—It is reported from Perth, under date of January 25, that an influential deputation has waited on the Minister of Public Works to complain of the great inconvenience and loss suffered by residents on account of the recent numerous delays and interruptions in the working of the telegraph lines in the colony, which, the deputation stated, had recently been in a terribly disorganised condition. This may be imagined when it is stated that the Press cables from England of January 19 appeared only in the newspapers of the 25th, and great indignation has been expressed in consequence. The Government is enquiring into the matter.

Systematic Teaching of Languages.—Those who are desirous of acquiring a perfect knowledge of both reading and conversing in foreign languages cannot do better than consult the pamphlet issued by the Central School Association, of Howard House, Arundel-street, Strand, W.C. Too little attention has been paid in the past to the most important point of conversational ability in other languages, and it is specially to drive home this weighty fact that the Central School was formed some two or three years ago. The great success of the school is due to the adoption of the "series" system of teaching, in conjunction with the use of mental visualisation and symbolic grammar. The history of the success of the school is given in the pamphlet, together with practical proofs of the satisfactory results obtained by those who have availed themselves of the benefits derived from attending the school.

New Swindon Junior Engineering Society.—A party of the members of this society travelled to Bristol on Saturday last for the purpose of paying visits to the Merchant Venturers' Technical College and the city electric lighting works. Arriving at the college at 3.30 p.m., they were conducted over the workshops and laboratories of this institution, which is under the control of Prof. J. Wertheimer, B.Sc., B.A. In the evening the party divided, one section proceeding to the electric lighting works at 6 p.m, the other making the visit at 11 p.m. This installation was found to be of exceptional interest, including as it does machinery of the most modern type. It was opened about two years ago, and has been supplying light to the city without a hitch since that time under the supervision of Mr. H. Faraday Proctor, to whom the society is indebted for permission to view it. The assistant engineer, Mr. R. W. L. Phillips, was most kind in his explanation of the switchboard and its instruments.

Laying of New Mains.—The Chelsea Electricity Supply Company desire to lay mains along the Chelsea-embankment and across the gardens there to the corner of Manor-street, and to construct draw-in and service boxes. It is proposed to lay the mains on the river side of the embankment, and consequently afterwards across the carriageway for the supply of the houses. The Highways Committee of the London County Council, however, think that some better arrangement should be made, and they therefore recommended on Tuesday that the Council should disapprove the works referred to. The Charing Cross and Strand Electricity Supply Corporation intend to lay mains on both sides of New-street, Covent Garden, and to construct two street boxes. The House-to-House Electric Light Supply Company want to lay mains in Evelyn-gardens and in Pembroke-gardens. Both high and low pressure mains are to be used. We wonder whether the present Highways Committee will be the Highways Committee next week, after the L.C.C. election. Let us wait until "the ball is over."

Metric System of Weights and Measures.—The Select Committee of the House of Commons appointed to enquire into the existing systems of weights and measures in this country, and whether any, and if so what, alterations are necessary, had a meeting on Tuesday under the presidency of Sir H. Roscoe. Evidence was given by Mr. H. J. Chaney, superintendent of the Standards Department of the Board of Trade, who described the system under which the verification of legal standards is carried on at the Board of Trade by experts appointed for the purpose, and also gave an account of the different systems of weights and measures now in use in the United Kingdom. He stated that the Imperial and the metric systems were the only ones with which the Department had to do in England, but there were other local customary weights and measures in use. Practically the only two countries of any importance in Europe in which the metric system was not adopted were Great Britain and Russia. In Germany, Austria, France, Italy, Spain, and Portugal the metric system was the only system in use.

Explosion at Euston.—An explosion in connection with the St. Pancras Vestry's electric installation took place at 7.50 p.m. on Saturday evening in Gee-street, Seymour-street, Euston-road, a few hundred yards from Endsleigh-gardens, where a similar explosion took place last December. As in the previous instance, the explosion was preceded by a low rumbling sound and directly afterwards the covers of two manholes, one in the roadway and the other on the pavement, were blown into the air, while the paving stones were dislodged for a space of four or five yards. The manholes are about 10 yards apart and are connected by culverts. The electric department of the Vestry and the Gaslight and Coke Company sent experts to make an examination. It is supposed that gas had accumulated in the manholes. Major Cardew has visited the place and will not hold an official enquiry, as the recommendations he made to the Department following the explosion in the Euston-road some few weeks ago were equally applicable to the present case. The Vestry are now engaged in making various alterations in accordance with Major Cardew's advice.

"Electric Measles."—Mr. George Anderson, in referring depreciatingly to the electric lighting of an Irish town, states that "we [the gas company] have got through the electric measles and still survive." Of course, that is due to living in Ireland. Everywhere, even in Ireland, this complaint is met with, and the worst of it is—for the gas companies at all events—that notwithstanding their endeavours to run down a successful competitor which is growing stronger every day, the electric light is becoming more popular and its use considerably extending. Mr. Anderson further says that "other corporations and other gas companies may have a touch of the disease." Of course they may, or, rather, they have already. It is truly unfortunate that a complaint of this dangerous nature should be permitted to develop in the alarming fashion prevailing at the present time, and we would suggest that Mr. Anderson should endeavour to induce the Board of Trade and Parliament to repeal the Electric Lighting Acts and the orders

Digitized by Google

under which electric stations are conducted. Then this dangerous epidemic, like the influenza, will no longer be a menace to the gas companies.

Clark Cell when Producing a Current.—Experiments detailed in a paper by Mr. S. Skinner in the *Philosophical Magazine* were made with the object of ascertaining how far the total E.M.F. round the circuit differs from that of the open cell, in the case of a Clark cell which is being used to produce a current, and how far this new value for the E.M.F. changes when the current is maintained. The experiments were made on three cells, all much larger than the ordinary Board of Trade pattern of Clark cell. It was assumed that the total E.M.F. round the circuit is equal to that of the cell at rest, and therefore that the E.M.F. overcoming polarisation can be obtained by subtracting from the E.M.F. of the cells at rest the observed current. In this way it was found that (1) the E.M.F. of polarisation varies directly with the current density in a particular cell; (2) the E.M.F. of polarisation slowly increases when the current is maintained. From the magnitudes of the quantities found in the experiments, it follows that small currents of approximately known values can be obtained by the use of Clark cells of small internal resistance which may be neglected in comparison with the large external resistance.

New York "Electric Power."—Like the New York *Electrical Review*, as shown in these columns last week, *Electric Power* has been wool gathering. It prints in its monthly issue of February a letter from Mr. H. Ler complaining of the small amount of space which we devoted to a review of the "Proceedings of the International Electrical Congress held at Chicago." If Mr. Ler will again read the review in question he will find that it is of a congratulatory nature. But *Electric Power* editorially supports its correspondent, writing in the following ungrammatical and meaningless style: "Our correspondent in another column is prone to take offence to (*sic*) a *criticism* of our English contemporary, the *Electrical Engineer's*, 'review,' on account of his rather curt dismissal of the new congress book." If this is a specimen of the style of *Electric Power*, its readers may congratulate themselves that the editor and associate editor are able to inflict upon them in one month only five pages of editorial matter printed in large type, followed by a catalogue of the contents of contemporaneous electrical journals. "Prodeegious!" as Dominie Sampson would say. *Electric Power*, by the way, has gladly availed itself of our columns for information concerning electrical work on the European continent—but generally without any acknowledgement. We do not foster any ill-will towards *Electric Power*, which we hope to meet and shake hands with at the next clambake. Till then, dear friend—peruse a grammar.

Meter Testing Charges of the L.C.C.—The London County Council, as announced in these columns at the time, fixed on November 6 a scale of fees to be charged for the testing of meters at the electric meter testing station at Cranbourne-street. The Highways Committee consider, however, that it is necessary that, in addition, a scale of fees should be adopted for other services not included in the scale referred to. They accordingly recommended to the Council on Tuesday that, until further order, the undermentioned fees be charged for the services specified: "For testing each 'disputed' meter the charge shall be in accordance with the scale adopted by the Council on November 6, 1894, and no reduction shall be made if a number be sent in together. For taking a record of 'pressure' at any consumer's house within three miles of the testing station, such record extending over 24 hours, 10s. 6d. If such record extends over two consecutive periods of 24 hours, for such second period, 5s. For testing a single pair of service lines, 10s. In difficult cases (in addition to the fee of 10s.), for every hour or part of an hour occupied after the first two hours, 3s. 6d." These fees are to include omnibus fares for the inspector, but all other travelling expenses are to be charged in addition. It is a pity the Highways Committee did not recommend cab fares. It would have been so much better. Recent experience has shown the benefits (!) of travelling on the Council's business or lack of business, and the result of being on the "Hi, hi, hi, clear away there, for I'll drive by."

A Gassy Argument.—Mr. S. W. Durkin, the president of the Southern District Association of Gas Engineers and Managers, evidently possesses great inventive ability. This is the way he explained to members of that association in annual assembly last week the reason for the adoption of the electric light throughout the country: "I cannot pass on without giving a word of praise to the Welsbach system, and I trust the weak point in that system will become stronger. I know with us three instances in which electric light has had to give way in its favour. I notice some portion of the electrical Press bespatter this innovation in artificial lighting, so that the presumption is that it is appreciated by the public, and is not detrimental to health, as they would have us believe, and as recently published evidence testifies. There is no doubt that a large amount of capital is being spent on electric lighting. It is quite fashionable, you know; and, Britisher-like, when we do go in for a new thing we do not know where to stop, especially when other people have to pay for it. It seems to me that there is too much capital lying idle in this country, and that Providence has opened up a way to get rid of a portion of it at the expense of the poor ratepayer, who can stand any burden his rulers put upon him." The president forgot to mention the thousands of cases where gas has been removed and the electric light introduced in its place. As to the Welsbach light, its sickly green glare, which is so obnoxious and irritating to the eye, will greatly restrict the adoption of this light. Can Mr. Durkin mention a single instance where the introduction of the electric light has been a burden to the ratepayer? We think not; but what other argument could be expected from the gas side?

Measurement of Strong Electric Currents.—The members of the Vienna Physico-Chemical Society assembled on February 5 to hear a paper, by Dr. Johann Sahulke, dealing with exact measurements of electric currents. After referring to the method adopted by the English Board of Trade, the author described a new system in which there are used two balances similar in construction to those introduced in England. Two circuits are required. By the aid of an electro-dynamic balance, one of these is maintained at about one ampere, so that with one balance for a maximum of one ampere the satisfactory exactness of measurement can be obtained. In this circuit is arranged the fixed coil of a second balance, the movable coil of which lies in shunt to a resistance through which the main current to be measured is passed. This resistance is formed of manganin sheets in order to counteract the effect of heating. The fall in pressure obtained in this resistance can be regulated so that it amounts to about two volts, and consequently the movable coil—no matter how great the main current to be ascertained may be—is always exposed to the same pressure of about two volts, and is, therefore, always traversed by an equal current. As the fixed coil is also traversed by an approximately constant current, the apparatus works continuously in the direction of its highest sensibility. In

Digitized by Google

this connection, the author stated that an exactitude of $\frac{1}{1000}$ can be attained. Whilst this method is specially intended for direct-current measurements, a similar system can be employed for alternating currents. In the latter case, the shunt to the manganin resistance is formed by the primary coil of a transformer having no iron, and having a ratio of transformation of 1 to 7. The secondary coil of the same gives the current which is led into the movable coil of the apparatus.

Does Electrocution Produce Instantaneous Death?—It was with a view to deciding whether execution by electricity, as practised in New York State, produces instantaneous, painless, and absolute death, that Messrs. A. E. Kennelly and Augustin H. Goelet, M.D., were deputed by the *Electrical World* of New York to be present at the execution of David Hampton, at Sing Sing prison, on January 28 last. It will be remembered that some observations by M. d'Arsonval led him to the conclusion that in electrical executions the death of the criminal was not produced by the passage of the current, but by the knife of the surgeon during the subsequent autopsy. On November 28 the *Electrical World*, in the desire to definitely settle this question, directed a letter to Governor Flower, of New York State, requesting that at the next electrical execution scientific witnesses should be selected whose duty should be to make such observations as would throw light upon the matter. This recommendation was favourably received, and Messrs. Kennelly and Goelet were appointed to perform this duty on the occasion of the twenty-fourth electrical execution in New York State. As a result of their observations, the writers conclude as follows: "The evidence is that a current of eight amperes, applied through the body at a pressure of 1,740 volts, and representing a power of (1,740 × 8 =) 13,920 watts, or about 18⅔ e.h.p., will produce instantaneous, painless, and absolute death; and that the evidence presented by an examination of the brain alone was sufficient to demonstrate the absolute impossibility of resuscitation. Although in our opinion there is no hope of resuscitation in cases where, as in this electrical execution, an alternating current of sufficient E.M.F. is deliberately sent through the body of the criminal, yet in all cases of accidental contact with high-pressure circuits, in our opinion, efforts for resuscitation should be made, since in most cases of accidents from electricity, either from the imperfection of the contact or its short duration, the current strength passing through the body and the electrical energy expended thereby might only be sufficient to produce a loss of consciousness."

A Theory of the Causes of Explosions.—Mr. Arthur Shippey has now come forward with a theory of the cause of explosions in connection with underground mains. The following note on the subject is culled from last week's *Gas World*, although we are under the impression that it appeared a few days previously in the *Pall Mall Gazette*. Let Mr. Shippey speak for himself: "My theory is that many of the explosions which have taken place, both here and on the Continent during the past ten years, have been caused by lightning flashes conveyed to the earth through lightning conductors, which need not—in order to cause an explosion—be fitted in the immediate vicinity. These atmospheric lightning waves are known to travel underground for miles, until they reach, or are absorbed by, water or damp earth, both of which have a great affinity for electricity. Then, again, it must not be forgotten that our principal thoroughfares, in which the electric mains are laid, are composed of a compound substance of a semi-metallic nature, consisting of earth and pulverised metals, brought into existence by reason of the wear and tear of thousands upon thousands of tons of iron tyres, carriage wheels, horseshoes, and other pulverised metallic substances. In this compressed compound there is laid a network of gas, water, and bare copper electric mains, a combination which forms an absolute and complete passage for the conveyance of the flashing currents. I base my theory on the fact that many explosions have occurred in districts where thunder and lightning have been hovering about in the vicinity, hence I am convinced that this is one of the real causes which has brought about the actual firing of explosive mixtures, which are allowed to accumulate in the culverts and manholes of some systems. I may just say that I think I have hit upon a plan which will entirely overcome the whole difficulty, but I must refrain for the present from divulging it. I think Sir David Salomons's suggestion [made in the *Electrical Engineer* a few weeks ago], to fill up the open spaces with sand-bags, to prevent accumulation of explosive gas, is a very good idea, and his plan should be thoroughly tried."

Low Temperatures and the Attractive Power of Magnets.—A communication was made to the French Académie des Sciences on February 4 by M. Raoul Pictet on the "Influence of Low Temperatures on the Attractive Power of Artificial Permanent Magnets." The author stated that the experiments referred to were made with a magnet weighing 493·5 grammes, and formed of three elements in horseshoe iron. After magnetisation, the magnet was made to carry its charged armature for two years. It could then sustain 4,275 grammes. It was subsequently left for 11 months without armature, and then could only bear 3,226·5 grammes. The magnet was then placed in a small frigorific vessel filled with pure alcohol; it was arranged vertically with the poles or branches in the air, and stayed with pieces of wood. The alcohol in which the magnet was placed was caused to touch the surface of a glass 3mm. thickness placed horizontally upon the branches. Two thermometers indicated the temperature of the alcohol, maintained constant by an agitator. The armature of the magnet in contact with the upper surface of the glass was fixed to the plate of a sensitive balance. It could only rise one-fifth of a millimetre, and was retained by two points closing an electric current which passed through a galvanometer. The following table gives the averages of the results obtained by four series of observations, in which the differences were always less than 1·50 grammes:

Temperature of the magnet. Degrees.	Power of magnetic attraction. Grammes.	Temperature of the magnet. Degrees.	Power of magnetic attraction. Grammes.
+ 30	57·31	− 40	66·70
+ 25	57·87	− 45	67·41
+ 20	58·48	− 50	68·45
+ 15	59·10	− 55	68·91
+ 10	59 81	− 60	69 64
+ 5	60·36	− 65	70 30
+ 0	61·04	− 70	71·12
− 5	61·80	− 75	71·98
− 10	62·42	− 80	72·70
− 15	63 42	− 85	73·41
− 20	63·93	− 90	74·18
− 25	64·60	− 95	74·95
− 30	65 35	− 100	75 80
− 35	66·09	− 105	76·64

The Government and Telephony.—Mr. H. Foster on Tuesday asked the Postmaster-General whether he was aware of a memorial or statement issued by the Corporations of Edinburgh, Glasgow, and Aberdeen urging that he should grant telephone licenses to municipal authorities, and protesting against the creation of a gigantic private

Digitized by Google

monopoly being conferred upon the National Telephone Company; whether this protest was supported by almost every municipal corporation in Great Britain; whether the negotiations referred to by the Chancellor of the Exchequer a few days since were with the municipal authorities; and whether he was able to state the present position of those negotiations. Mr. A. Morley replied: I have received memorials from the Corporations of Glasgow, Aberdeen, and other towns in Scotland, urging that the Government should itself assume the working of the telephones, or that licenses should be granted to municipal authorities. I have also received a deputation, representing the corporations of Edinburgh, Glasgow, and Aberdeen, in support of those views, and objecting to the monopoly of the National Telephone Company. But I have not received any protest in writing from Scottish corporations or from municipal corporations in Great Britain such as that referred to by the hon. member. The negotiations referred to by the Chancellor of the Exchequer simply had reference to an arrangement for discussing the telephone question prior to the agreement with the telephone company being signed, and this opportunity for discussion will, I hope, be afforded on Friday next, on the motion of the hon. member for the St. George's Division of the Tower Hamlets." The following is the text of Mr. Benn's motion respecting telephone licenses, which has the first place at the evening sitting to-day (Friday): "That a Select Committee be appointed to consider the proposed draft agreement between the Postmaster-General and the National Telephone Company, and report with reference to the monopoly which may thereby be created; the granting of telephone licenses to municipalities; and generally on the future policy of the Post Office with reference to the extension of the telephone service." At a meeting of Scotch members held in one of the committee-rooms of the House of Commons on Wednesday, Sir C. Cameron presiding, it was agreed to support this resolution, and an interesting debate is anticipated.

Investigation of a Rotary Field.—In the course of a mathematical article published in the *Elektrotechnische Zeitschrift* of February 21, on the "Investigation of a Rotary Field," Mr. O. S. Bragstad states, in connection with the necessity for special knowledge of the properties of rotary-current motors, that very little valuable information is available on the subject. The author has therefore endeavoured to throw some light upon the matter, his paper being confined to a method of investigating rotary-current motors. The measurements were carried out with an old two-phase motor having eight pole-pieces and a "perforated" armature with a short-circuited drum winding. The most important dimensions of the motor are as follow:

Circumference of armature	62	centimetres.
Length of armature	15·5	,,
Length of pole-pieces (parallel to the shaft)	16·5	,,
Width of pole-pieces	3·7	,,
Height (radial) of pole-pieces	2·3	,,
Radial height of the armature iron	3·9	,,

The experiments were confined to measurements with a continuous current and with a revolving armature. As a result of the investigation, the author stated that on light running, to which the measurements related, currents upon which a positive turning moment is exercised exist almost only between two pole-pieces. The latter is in a great part compensated by means of a counter turning moment in the points of strongest induction. The resulting armature currents cause a lot of work on light running, and bring about injurious heating of the armature. With a load the currents are in front of the pole-pieces, and even if they are not negative in consequence of the small armature speed they are very weak, whilst the strongest currents between the pole-pieces in relation to the production of circumferential power, are badly utilised on account of the there existing weak magnetic induction. The author concludes, therefore, that endeavours should be made to obtain the strongest currents where the normal component of magnetic induction is the strongest. The efforts of practice in the direction of constant "speed of field" lead to this object, and they are justified in so doing. The degree to which the object can be attained must be ascertained by measurements with modern machines. In previous experiments made under similar conditions it was found that the efficiency of the motor at a performance of 234 watts was 17 per cent., the work on running light requiring 1,000 watts.

Electric Lifts.—The fatal accident which took place a few days ago in the City in the working of a lift brings forward once more the question of substituting electric lifts for those operated by hydraulic power and other means. In this connection the New York *Electrical Engineer*, in discussing the passing of the hydraulic elevator, makes some pertinent remarks. Our contemporary says: For ordinary buildings of a few storeys in height, many hundreds of electric elevators have already proved their value, and some idea of the extent of this work may be gathered from the statement that in New York City alone there are connected to the Edison service mains no fewer than 250 elevators, aggregating 3,000 h.p. This class of electric elevator service presented no particular difficulties in the past, but the high-duty service requisite in buildings ranging anywhere between 10 and 25 storeys presented a problem which even the boldest of electrical engineers have shrunk from attempting until within quite a recent period. Indeed, it took the courage of conviction and the electrical skill of Mr. Frank J. Sprague, aided by the mechanical ingenuity of Mr. Chas. R. Pratt, to bring the electric elevator to a point where it could successfully compete with the high-duty hydraulic elevator. The great Parrot Building, San Francisco, is now being equipped with no fewer than 15 Sprague-Pratt elevators, and this must be considered conclusive evidence of the fact that the electric elevator has come to be recognised as the standard high-duty elevator of the world. The continued experience with the Sprague-Pratt elevators in the Postal Telegraph Building in New York more than confirms the estimate put upon them, and while we do not suppose that hydraulic elevator building will cease at once, we are convinced that the days of the hydraulic elevator as the standard are numbered. While the experience of the Postal Telegraph Building and of other buildings with other types has already proved the economy of such elevator service, it might be well to emphasise the fact, or point, that an ideal condition of affairs could be realised in electric elevator service by the introduction of storage batteries. The service, being highly intermittent in character, presents the best conditions for economical working in connection with storage. But there is another immense superiority over the hydraulic elevator. In the case of the latter, the storage tank under the best conditions would probably be able to afford scarcely half-a-dozen trips after the shutting down of the pumps, whereas a storage battery, occupying the same space as the water-tank of the hydraulic elevator, would store perhaps twenty times the energy contained in the stored water, or, in other words, allow of over a hundred elevator trips. Besides this, there would be an additional advantage in the decreased size and cost of the steam and electric plant, due to its operating at maximum power at all times independent of the elevator load.

WATERLOO AND CITY ELECTRIC RAILWAY.

The directors of the South-Western Railway have long felt that the situation of Waterloo Station placed them at a considerable disadvantage, as compared with lines having a terminus north of the Thames, and the various proposals for getting over this difficulty were discussed years ago. When the City and South London Railway became an accomplished fact, it was at once seen that there were many other places in which the same system could be advantageously applied. The use of electric traction reduced the ventilation required to a minimum, whilst the expense of construction could be materially decreased by keeping the tunnel at a depth below the sewers or the foundations of existing buildings. Amongst others, the directors of the South-Western Railway decided that by adopting the Greathead system it would be possible to run a line from their terminus to the City at a cost likely to make the outlay remunerative, and accordingly the Waterloo and City Railway Company was constituted. This, though a separate company, has the same directors as the South-Western, of which it will practically form a branch or feeder. The line will commence under Waterloo Station, where the rail level will be 36ft. below that of the South-Western Railway, and will finish in Queen Victoria-street, between Queen-street and Bucklersbury, close to the Mansion House, and consequently to the Bank of England and the Royal Exchange. The rail level here will be 65ft. below that of the thoroughfare, and hydraulic lifts will be provided, but at the other end this has not been considered necessary, especially as the electric station will have to be connected with the various platforms. There will be no intermediate station, and it is expected that the time occupied in the journey will be about four minutes. As the distance is a little over a mile and a half, this will give an average speed of 22 miles an hour. Like the City and South London, the up and down lines will be in separate tunnels. These tunnels will not necessarily, nor even usually, be on the same level, nor will they always be the same distance apart. As a rule, there will be about 4ft. between the outsides of the tubes, but in some parts they will be brought much closer together, so as to keep both lines as much as possible under existing roadways. The steepest incline will be 1 in 30, which will be the gradient at which the line from Waterloo to the City will leave the former station, so that it will be with the load. The steepest against the load will be 1 in 60, which will be the incline at which the other line will enter Waterloo.

The engineers for this company are Messrs. Galbraith and Greathead; Mr. H. H. Dalrymple Hay, A.M.I.C.E., being the resident engineer. The contract for the construction of the tunnels from Cross-street, near Waterloo Station, to the City, and for the City terminus, has been let to Messrs. John Mowlem and Co., who are represented on the site by Mr. W. Rowell. The contract was signed last June, and in July the contractors commenced driving the piles for a stage which they have put up in the Thames, just above Blackfriars Bridge. This stage is close to the Surrey shore, to which it is connected by a gangway leading to it from Upper Ground-street. As soon as it was completed two iron cylinders were sunk from it into the bed of the river, entering the clay to a depth of 13ft. When the contents of these cylinders had been excavated the shafts were continued and were lined with brickwork, the first 10ft. of this being 1ft. 6in. thick, followed by 17ft. of 2ft. 3in. thick, which reached to the bottom of the tunnels. The upper part of the brickwork is circular, like the cylinder, but its section is gradually changed, so that at the bottom the shafts have two flat sides at right angles to the axis of the tunnels, the section being very nearly a square with rounded ends. This part of the work was completed last October, and the shields for the four headings were then lowered in pieces and put together at the bottom of the shafts. A temporary doorway connects the bottom of the two shafts, but there will be no further connection between the up and down tunnels until they meet at Waterloo or the City. The soil at the bottom of the shafts was found to be blue London clay, and up to the present the nature of the ground has not varied; so that there has been absolutely no infiltration of water, and therefore no necessity to use compressed air. But by the end of March the headings towards Waterloo will have risen sufficiently to penetrate into ground which borings have shown to consist chiefly of ballast. Here it is expected that water will be encountered in considerable quantities, and consequently it will be necessary to excavate under pressure. Preparations have been made for this; the air-locks are ready to be put up when required, and a fine pair of air-compressors, by Messrs. Markham and Co., Limited, of Chesterfield, are on the stage, ready to be started. The cast-iron tubes, which are being made by Messrs. Head, Wrightson, and Co., Limited, are in sections 20in. long, each section consisting of seven segments and a key-piece at the top. All joints are planed and are radial to the centre of the tunnel, excepting the sides of the key-pieces, which are parallel, so that they may be inserted more easily. The segments are joined together, and the separate sections of the tube are also connected, by means of turned bolts, 1in. diameter. There is no packing between the segments, but a thin wooden packing between each ring. Going from the starting point towards the City, the tubes are 12ft. 1¾in. internal diameter and 13ft. external; but towards Waterloo, where there are several sharp curves (one of which, five chains radius, is already completed), the diameters are 12ft. 9in. internal and 13ft. 7¼in. external. The increased size has been necessary to prevent the carriages from fouling the sides when going round curves.

The shields used for excavating are similar to those employed on the City and South London Railway. They are pushed forward by eight hydraulic jacks, pressing against packings which bear on the finished part of the tube, and spaced at equal distances round its circumference. By working some of the hydraulic jacks and stopping the others, the direction of the shield can be varied as may be desired. An advance heading, strongly timbered, is kept a few feet in front of the shield; and the excavation is done entirely by means of pick and shovel. The soil dug out is loaded at once into skips, which stand on a low-platform truck running on rails 20in. gauge. At present these are pushed by hand to the shaft, where they are hoisted by a steam crane and emptied into barges. Later on, the haulage will be done by electric locomotives: one of these, by Messrs. Siemens Bros., has just been delivered on the works. The work is carried on by day and night gangs, but stops altogether on Sundays. The maximum advance in the 24 hours has been 10ft. On February 21, 390ft. of the up tunnel had been constructed towards Waterloo, and 500ft. towards the City. The down tunnel extended 80ft. towards Waterloo and 200ft. towards the City. As a test of accuracy, boreholes are being put down, both on the Middlesex and Surrey sides of the river, so that the line may be plummed from the surface; but it is not proposed to make openings for any other purpose until the ends of the line are reached. As each segment is put together inside the shield, before the latter is moved forward, an annular space of about ¼in. is left between the outside of the tube and the surrounding ground. This is filled with a grouting composed of blue lias lime and sand. A hole is left in the centre of each segment into which a hose is inserted, leading from an iron vessel, called a "bougie." The lime and sand are mixed in this with water; and then, whilst a handle is continually turned to keep the mixture homogeneous, air, at a pressure of 20lb. to the square inch, is admitted, and the grouting is forced through the hose into the vacant space. At the stations, the two tubes will be united in one, also of cast iron, and 23ft. internal diameter.

The line, after leaving Cross-street, passes under the Waterloo-road and along Stamford-street to Hatfield-street. Here there are several rather sharp curves, to avoid private property as much as possible, and then the river is reached. On the north side of the Thames it will pass under the District Railway, where the rails will be 53ft. below those of the existing line. Another curve brings it under Queen Victoria-street, and its centre line will

Digitized by Google

practically coincide with that of the street till the terminus is reached. During part of its course up this street (from St. Andrew's-hill to Friday-street) its centre line will also be exactly under that of the District Railway, the difference between the rail levels being 45ft. to 53ft. The dynamos and electric lighting plant used in the tunnels are by Messrs. Paterson and Cooper, of Victoria-street. It is expected that the line will be opened to the public during the latter part of next year. The details of the permanent electric system have not yet been settled, as the engineers consider it premature to do this until the tunnels are further advanced.

CITY AND GUILDS OF LONDON INSTITUTE.

We have received a copy of the report of the results of the work done at this institution during the year or session 1893 94. An abstract is given below: For two years there has been a decrease, not large, but still not unimportant, in the number of candidates at the entrance examination. One cause is the great increase of facilities for obtaining technical education in London and in the provinces since the college opened. Probably, however, the falling off in the number of candidates for admission this year is chiefly due to the continued commercial depression. The Siemens memorial scholarship, which is offered every third year, was awarded to Mr. F. Twyman, who has been educated at the City and Guilds Technical College, Finsbury. The diploma of associate of the institute (A.C.G.I.) is granted to students who have followed one of the three prescribed courses, including instruction in all four departments (mathematics, engineering, physics, and chemistry), and who have passed the sessional examinations with credit. This year, 46 matriculated third-year students were examined, and 30 were recommended for the diploma of associate of the institute. The highest place in the class list was taken by Mr. F. Maeers, a student of the engineering department. Mr. Maeers was educated at St. Dunstan's College, and obtained the Siemens scholarship at the matriculation examination in 1891; at the end of his second year's course he was awarded the John Samuel scholarship. Mr. H. C. Leake, the John Samuel scholar of last year, who received a diploma in civil and mechanical engineering, re-entered the college in the department of electrical engineering, and this year has taken a diploma in electrical engineering. Hitherto, one Siemens medal has been annually awarded in the physical department, usually to the student who did best in the third year of the course. This year Lady Siemens has graciously given consent to the annual award of two Siemens medals—one in the department of civil and mechanical engineering, and one, as before, in the department of electrical engineering. These medals have been awarded to Mr. F. Maeers in the engineering department, and to Mr. H. C. Leake in the physics department. The plan of awarding a works scholarship to meritorious students of moderate means, to help them to enter works where they would obtain good practical experience, was first tried last year. This year the engineering premium was awarded to Mr. F. Maeers, who has become a member of the private staff of Mr. L. J. Seymour, the managing director of the works of Messrs. Fraser and Chalmers, at Erith. A fellowship has been conferred by the council of the institute on Dr. W. E. Sumpner. A table given in the report affords such particulars as are known of the career, after leaving the college, of those students who have followed a regular course of instruction and who have gained a diploma. Most of the students who left the college in July have obtained employment with remuneration, or as improvers with small wages, or as pupils by paying a premium. In the physical department, Dr. Sumpner, who left the institute's service to take an appointment as head of the electrical department of the Battersea Polytechnic, and who has recently been appointed principal of the Birmingham Municipal School, has been replaced by Mr. W. G. Rhodes. Mr. P. G. Ledger, who held the position of assistant demonstrator, has been replaced by Mr. A. H. Allen.

PORTABLE TELEPHONE APPARATUS.

Attention has been directed for a good many years, successfully in many cases, to the construction of apparatus which allow of simultaneous and independent signals being transmitted over the same wire. It is of importance to be able to use a telegraph wire for telephonic communications without disturbing the Morse signals. For this purpose, Mr. J. Berliner, of Hanover, has invented a portable telephone apparatus, which is being used in connection with stationary appliances in Germany and elsewhere. The portable arrangement comprises a Ruhmkorff induction coil, for calling up with automatic interruption; a micro-telephone with universal transmitter and automatic switch; a box telephone; an automatic switch for switching off the battery; a wire condenser; a push button, with one non-working and two working contacts; four dry cells; three connecting terminals for the line and earth; 20ft. of double cable with four connecting plugs; and one terminal for the earth connection by screwing to a rail. The apparatus is carried in an oak box, the whole weighing 15lb. The arrangement is intended to be used in connection with telegraph wires on open tracks, in order that conversation can be had with the next railway station. For Fig. 1, which shows the apparatus, and Fig. 2, a diagram, we are indebted to the *Elektrotechnischer Anzeiger* of Berlin. The method of operation is as follows: A jointed rod is put together and hooked on a wire connecting with the next station's fixed apparatus. The plug connected with the rod is inserted in the plughole L in the diagram. A connection is then made between the plughole E and a railway rail. In case the wire in question is not being used for telegraphic transmission, the plug connected with earth (the rail), is pushed into the plughole Y. This switches out the condenser, and in consequence audibility

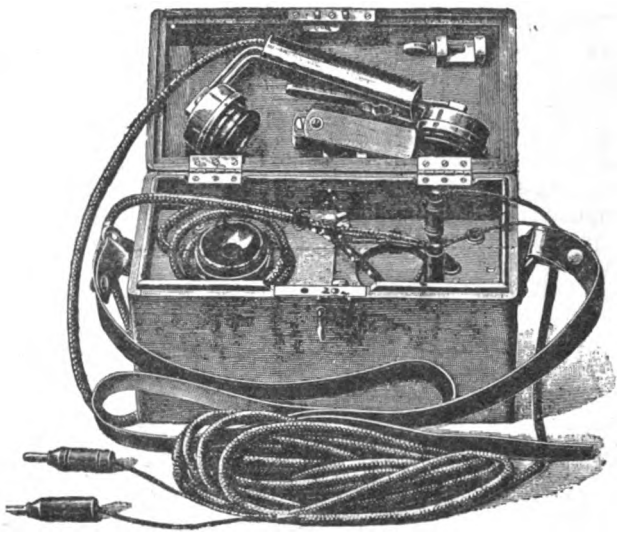

Fig. 1.

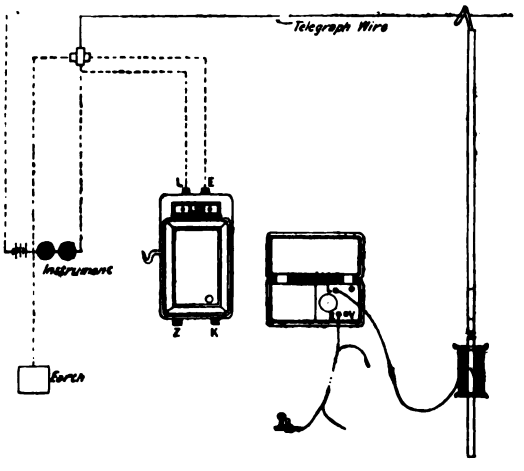

Fig. 2.

Digitized by Google

will be increased. The telephone is next taken out of its case, which causes the battery to be switched in. The signal is given by pressing the button, which causes a loud buzzing in the telephones of the station called up. The reply signal having been received conversation can take place. During conversation the switch in the handle of the micro-telephone must be pressed.

EFFECT OF ARMATURE CURRENT ON MAGNETIC LEAKAGE.

This subject is discussed by Messrs. H. D. Frisbee and Alex. Stratton in their graduation thesis in electrical engineering, Columbia College. The following is an abstract:

Several investigations have been recorded, which have had for their object to determine the extent and distribution of magnetic leakage in dynamos and motors, and many formulas have been deduced from a theoretical standpoint, to predict the magnitude of the stray field of a machine from its dimensions. But up to the present time very little notice has been taken of the fact that the current in the armature usually has considerable effect on the magnetic leakage of a machine, and, therefore, the present experiments were made with the object of determining the nature and amount of this influence. With this end in view, four machines were chosen, representing widely different types: (1) Crocker-Wheeler 5-h.p. motor (over type); (2) Crocker-Wheeler 5-h.p. compound dynamo (over type); (3) 1½-kilowatt Edison shunt dynamo (under type, or horseshoe type); (4) 2 h.p. Sprague motor (consequent pole, or Manchester type). The two 5-h.p. machines were exactly alike in their frames and armatures, the only difference being in the winding of the field coils. This gave an excellent opportunity to make a comparison between the effect of armature reaction when opposed to a shunt field and when opposed to a compound field.

The general conclusions arrived at by the writers are as follow:

A careful consideration of the machines shows that similar actions take place in all the types, the difference being principally in degree. The following points are of interest:

(1) The change of flux in the pole-pieces when current was passed through the armature caused increased induction in one pole-piece and corresponding decrease of induction in the other, this being the case even with the compound-wound machine.

(2) The magnetic effect of the armature current is more marked in machines which have (*a*) armatures of large diameter; (*b*) ring winding.

(3) With a large air-gap, as in smooth-core armatures, the coefficient of leakage is very large, but this coefficient is less affected by armature reaction. Conversely, with small air-gap, as in toothed armatures, the coefficient of leakage is small, but this coefficient is more affected by armature reaction. Freedom from armature reaction means large increase in the ampere-turns on the field.

(4) With proper construction of the pole-pieces, armature reaction is not such a thing to be dreaded—that is, if the air-gap provides ample space for the shifting of the lines of force consequent on loading the machine, the armature reaction does not cause marked trouble. Indeed, this same armature reaction can be made to keep the speed of a motor constant under all loads, or the motor can even be made to increase its speed with the load. In short, the advantages of differential winding can be obtained in a simpler way, and without the danger of entirely destroying or even reversing the field magnetism when the motor is overloaded.

This may be inferred from the fact that the 5-h.p. C.-W. motor before mentioned was made to increase its speed considerably at full load by inserting resistance in the field winding, thus weakening the magnet. The same action would undoubtedly take place if the pole-pieces were so shaped as to partially throttle the lines of force when the field was distorted by armature reaction.

POWDERED LEAD ACCUMULATORS.

The Compagnie Française pour la Pulverisation des Metaux have taken up the manufacture of secondary batteries based upon the use as active material of pure and very fine lead powder, which is obtained by a mechanical process, and which is subsequently mixed with a very porous inert material. The plates serving as electrodes are provided with this active material. These plates, one of which is shown in Fig. 1, are formed of "ribbons" of lead, having furrows formed dove-tail fashion. According to the makers, the employment of pure lead has a great advantage over the oxides of lead ordinarily used, as the active material thus obtained, forming

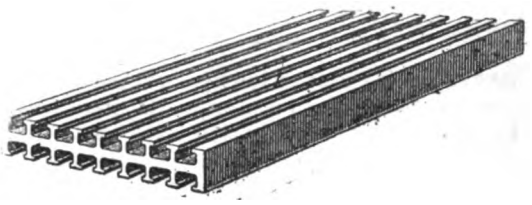

FIG. 1.

a common body with its support, the contact between the two is perfect from an electrical point of view. Moreover, the mixture of lead powder and the inert material constituting a compound having a great degree of porosity, the electrolyte is able to better penetrate the mass, and consequently the chemical work is much more complete, the result being a very high capacity and efficiency. Another advantage claimed for this type of plate is the obviation of the disintegration of the plates. The makers produce two types of cells. The first is arranged in a glass case for capacities varying from 32 to 500 ampere-hours; the weight of the complete cell ranges from 12 to 67 kilogrammes.

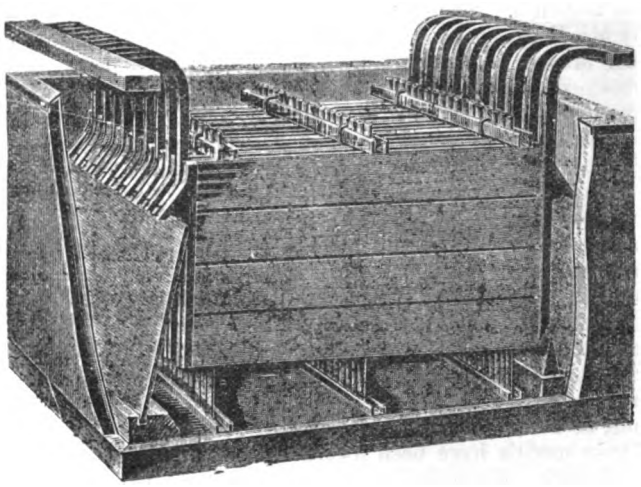

FIG. 2.

The second type, which is represented in Fig. 2, contains electrodes placed in lead-sheathed wooden boxes. The cells of this type are constructed for capacities varying from 336 to 2,640 ampere-hours; the weight of one complete cell of the smallest form is 91 kilogrammes, and of the heaviest, 363 kilogrammes.

In the fitting of these cells, each plate, according to the capacity to be obtained, is formed with the assistance of a variable number of standard or unit plates of the same dimensions. The latter are soldered in a lead frame, which carries on each side an iron projection allowing of the suspension of each electrode from two insulating supports, usually of glass, and arranged inside the case or box. The distance between the electrodes is maintained invariable by means of glass tubes placed vertically and resting at their lower ends in a furrow made at the bottom of the case, whilst their upper ends are held between two glass rules. All the connections are made by soldering. The electrolyte used is water acidulated by pure sulphuric acid of a density of 1·20deg. or 24deg. Baumé.

Digitized by Google

As stated by the makers, the capacity of a cell of the first type, weighing 36 kilogrammes, and being 25 centimetres long, 33 centimetres wide, and 38 centimetres deep, is as follows:

	Rate of discharge in amperes.	Capacity in ampere-hours.
Discharge in four hours.....	40	160
Discharge in five hours	35	175
Discharge in six hours	31·7	190
Discharge in eight hours	28·1	225
Discharge in ten hours	25·0	250

The average E.M.F. of the cell, with a cell having a five hours' discharge, is 1·93 volts. The discharge should normally be stopped at 1·85 volts, although it can be continued without injury to a lower figure. These accumulators can be discharged in less than four hours, and in this case the final voltage can be allowed to fall to 1·80 volts. The makers guarantee the cells for two years, and they will undertake for 10 years the maintenance of the accumulators on the annual payment of from 4 to 10 per cent. of the purchase price.

PRACTICAL NOTES ON DYNAMO CALCULATION.*

BY ALFRED E. WIENER.

PART III.—DIMENSIONING OF FIELD-MAGNET FRAME.

1.—General Construction Rules.

(41) *Forms of Field Magnets.*—With reference to the type of the field-magnet frame, modern dynamos may be classified as follows:

I.—Bipolar Machines.

(1) Single-horseshoe type—(*a*) upright single-horseshoe type (Fig. 67); (*b*) inverted single horseshoe type (Fig. 68); (*c*) horizontal single-horseshoe type (Fig. 69); (*d*) vertical single-horseshoe type (Fig. 70).

(2) Single-magnet type—(*a*) horizontal single-magnet type (Figs. 71 and 72); (*b*) vertical single-magnet type (Fig. 73); (*c*) single-magnet ring type (Fig. 74).

(3) Double-magnet type—(*a*) horizontal double-magnet type (Figs. 75 and 77); (*b*) vertical double-magnet type (Figs. 76 and 79); (*c*) inclined double-magnet type (Fig. 78); (*d*) double-magnet ring type (Fig. 80).

(4) Double-horseshoe type—(*a*) horizontal double-horseshoe type (Fig. 81); (*b*) vertical double-horseshoe type (Fig. 82).

(5) Iron-clad type—(*a*) horizontal iron-clad type (Figs. 83 and 84); (*b*) vertical iron-clad type; single-magnet vertical iron-clad type (Figs. 85 and 86); double-magnet vertical iron-clad type (Fig. 87).

II.—Multipolar Machines.

(1) Radial multipolar type—(*a*) radial outer-pole type (Fig. 88); (*b*) radial inner-pole type (Fig. 89).

(2) Tangential multipolar type—(*a*) tangential outer-pole type (Fig. 90); (*b*) tangential inner-pole type (Fig. 91).

(3) Axial multipolar type (Fig. 92).

(4) Radi-tangent multipolar type (Fig. 93).

(5) Single-magnet multipolar type—(*a*) axial pole single-magnet M.P. type (Fig. 94); (*b*) outer inner-pole magnet M.P. type (Fig. 95).

(6) Double-magnet multipolar type (Fig. 96).

(7) Multipolar iron-clad type (Fig. 97). Horizontal four-polar iron-clad type (Figs. 98 and 100).

(8) Multiple-horseshoe type (Figs. 101 and 102).

(9) Quadruple-magnet type (Fig. 103).

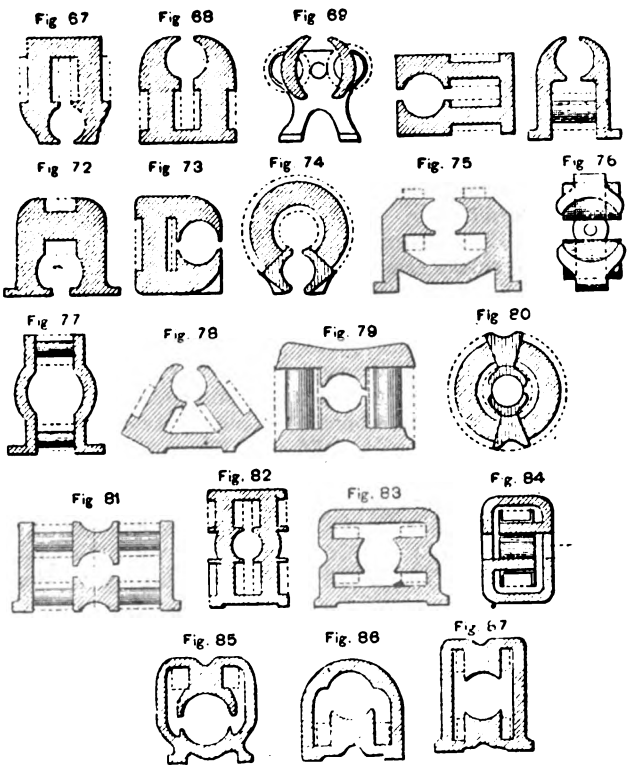
(10) Four-polar double-magnet type (Fig. 104).

(*a*) *Bipolar Types.*—The simplest form of field-magnet frame is that resembling the shape of a horseshoe. Such a horseshoe-shaped frame may be composed of two magnet cores joined by a yoke, or may be formed of but one electromagnet provided with suitably shaped pole-pieces. The former is called the "single-horseshoe type," the latter the "single-magnet type."

A single-horseshoe frame may be placed in four different positions with reference to the armature, the two cores either being above or below the armature, or situated symmetrically, one on each side, in a horizontal or in a vertical position.

The upright single-horseshoe type, Fig. 67, is the realisation of the first-named arrangement, having the cores above the armature, and is therefore often called the "overtype." This form is now used in the Edison dynamo, built by the General Electric Company, Schenectady, N.Y., in the motors of the C. & C. Electric Company, New York, and is further employed by the E. G. Bernard Company, Troy, N.Y.; by the Detroit Electrical Works, Detroit, Mich. ("King" dynamo); the Commercial Electric Company (A. D. Adams), Indianapolis, Ind.; the Novelty Electric Company, Philadelphia, Pa.; the Electron Manufacturing Company (Perret"), Springfield, Mass.; by Siemens Bros., London, England; Mather and Platt (Hopkinson), Manchester, England; the India Rubber, Gutta Percha, and Telegraph Works Company, Silvertown, England; and by Clarke, Muirhead, and Co., London.

The inverted horseshoe type, Fig. 68, having the cores below the armature, is also called the "under-type." Of this form are the General Electric Company's "Thomson-Houston" motors, the standard motors of the Crocker-Wheeler Electric Company, Ampère, N. J.; further, machines of the Keystone Electric Company, Erie, Pa.;



the Belknap Motor Company, Portland, Me.; the Holtzer-Cabot Electric Company, Boston, Mass.; the Card Electric Motor and Dynamo Company, Cincinnati, O.; the La Roche Electrical Works, Philadelphia, Pa.; the Excelsior Electric Company, New York; the Zucker and Levett Chemical Company, New York (American "Giant" dynamo); the Knapp Electric and Novelty Company, New York; the Aurora Electric Company, Philadelphia, Pa.; the Detroit Motor Company, Detroit, Mich.; the National Electric Manufacturing Company, Eau Claire, Wis.; Paterson and Cooper (Esson), London; Johnson and Phillips (Kapp), London; Siemens and Halske, Berlin, Germany; and Ganz and Co., Budapest, Austria.

Machines of the horizontal single-horseshoe type, Fig. 69, in which the centre lines of the two magnet cores and the axis of the armature lie in the same horizontal plane, are built by the Jenney Electric Company, New Bedford, Mass. ("Star" dynamo), by the Great Western Manufacturing Company (Bain), Chicago, Ill., and by O. L. Kummer and Co., Dresden, Germany.

The vertical single-horseshoe type, Fig. 70, finally, having the axes of magnet cores and armature in one vertical plane, is employed by the Excelsior Electric Company (Hochhausen), New York, and by the Donaldson-Macrae Electric Company, Baltimore, Md.

* From the *Electrical World* (New York).

Digitized by Google

Single-core horseshoe frames may be designed by placing the magnet either in a horizontal or in a vertical position, or by joining two pole-pieces of suitable shape by a magnet of circular form. The types thus obtained are the horizontal single-magnet type, the vertical single-magnet type, and the single-magnet ring type.

In the horizontal single-magnet type, Figs. 71 and 72 respectively, the armature may either be situated above or below the core. Machines of the former type, Fig. 71, are built by the Jenney Electric Motor Company, Indianapolis, Ind.; the Porter Standard Motor Company, New York; the Fort Wayne Electric Company, Fort Wayne, Ind.; the United States Electrical Company, New York; the Holtzer-Cabot Electric Company, Boston; the Card Electric Motor and Dynamo Company, Cincinnatti, O.; the Simpson Electrical Manufacturing Company; the Chicago Electric Motor Company, Chicago; the Bernstein Electric Company, Boston; and by the Premier Electric Company, Brooklyn. The latter type, Fig. 72, is employed by the Electron Manufacturing Company, Springfield, Mass.; and by the Riker Electric Motor Company, Brooklyn.

The vertical single-magnet type, Fig. 73, is used by the "D. & D." Electrical Manufacturing Company, Minneapolis, Minn.; the Packard Electric Company, Warren, O.; the Boston Fan Motor Company, Boston; the Elbridge Electrical Manufacturing Company, Elbridge, N.Y.; the Woodside Electrical Works (Rankin-Kennedy), Glasgow, Scotland; by Greenwood and Batley, Leeds, England; and by Goolden and Trotter (Atkinson), England.

Fig. 74 shows the single-magnet ring type, which is employed by the Mather Electric Company, Manchester, Conn. Two magnets, instead of forming the limbs of a horseshoe, can also be set in line with each other, one on each side of the armature, or may be arranged so as to be symmetrical to the armature, but with like poles pointing to the same direction, instead of forming a single magnetic circuit with salient poles; the form will then constitute a double circuit with consequent poles in the yokes joining the respective ends of the magnet cores. In both of these cases the cores may be put in a horizontal or vertical position, and in consequence we obtain two horizontal double-magnet types, Figs. 75 and 77, and two vertical double-magnet types, Figs. 76 and 79.

The salient pole horizontal double-magnet type, Fig. 75, is employed by Naglo Bros., Berlin, and by Fein and Co., Stuttgart, Germany; and the salient pole vertical double-magnet type, Fig. 76, by the Edison Manufacturing Company, New York.

The consequent pole horizontal double-magnet type, Fig. 77, is used in the Feldkamp motor, built by the Electrical Press Company, Newark, N.J., and in the Fan motor of the De Mott Motor and Battery Company; and the consequent pole vertical double-magnet type, Fig. 79, by the Columbia Electric Company, Worcester, Mass.; the Keystone Electric Company, Erie, Pa.; the Akron Electrical Manufacturing Company, Akron, O.; the Mather Electric Company, Manchester, Conn.; the Duplex Electric Company, Corry, Pa.; the General Electric Traction Company (Snell), England; Mather and Platt (Hopkinson), Manchester, England; Immisch and Co., England; Oerlikon Works (Brown), Zurich, Switzerland; and Helios Company, Cologne.

If in the latter form magnets are made of circular shape the double-magnet ring type, Fig. 80, is obtained, which is built by the "C. & C." Electric Company, New York, and which has been used in the Griscom motor of the Electro-dynamic Company, Philadelphia.

The inclined double-magnet type, illustrated in Fig. 78, forms the connecting link between the double-magnet and the single-horseshoe types; it is employed by the Baxter Electrical Manufacturing Company, Baltimore, Md.; by Fein and Co., Stuttgart; and by Schorer, in Darmstadt.

(To be continued.)

Long Telegraph Line.—The longest telegraph line in the world is said to extend from Old Broad-street, London, to Calcutta, a distance of over 7,000 miles.

THE PRACTICAL APPLICATION OF ALTERNATING-CURRENT MOTORS.*

BY WALTER J. FRYER, A I.E.E.

It will perhaps be as well for us to first consider alternating currents from their theoretical aspect, and to afterwards follow on with illustrations of how alternating-current motors have been successfully applied in practice.

In England, all the companies supplying alternating currents use what is called the single-phase system of distribution, and owing to the demand for motors being very small they have not seen their way clear to lay down a separate system of mains. All motors have, therefore, to be connected up to the lighting circuits. Extreme care is necessary in designing installations where such motors are to be used owing to their taking a very large starting current, which would cause the pressure at the lamp terminals to vary greatly. One of the chief difficulties of running single-phase motors off lighting circuits is, that until quite recently they had only been designed to work where the frequency did not exceed 30 cycles per second. With lighting, it is both necessary and economical to have the frequency as high as 80, 100, or 130 cycles per second, as the eye can easily detect the variations in an incandescent lamp that is being supplied with the alternating current at a frequency of 30 to 40 cycles per second. Hence it was out of the question to think of supplying motors and lamps with electrical energy from the same circuit. These difficulties have been overcome, and they are now made to work with frequencies as high as 100 cycles per second. The frequency of a generator depends upon the number of revolutions per second of the armature, and upon the number of pairs of poles upon the field.

Another objection which is sometimes raised against single-phase alternate motors is that they have dead points at every reversal of the current. This is not a serious one, as they are so small and so numerous that they practically become of no account. There are sometimes as many as 200 of them in a second; not only so, but these dead points occur only when the rotor—that is to say, the revolving part of the machine—is not running in synchronism with the generator. Directly synchronism is obtained these dead points are eliminated. The motor must therefore be brought up to the same speed as the generator before closing the switches. Another way of attaining this end is by causing the resultant magnetic force to pass successively through a series of poles on the field in a rotary manner, giving a two-phase or multiphase machine. It can easily be seen that the lower the ⌣⌢ the greater will be the difficulty from dead points.

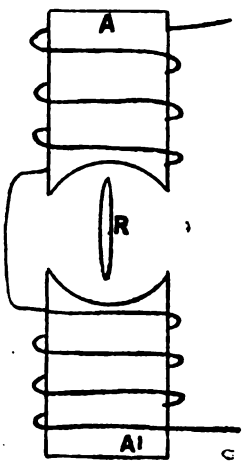


FIG. 1.

Referring to Fig. 1, A and A^1 are electromagnets. If we pass an alternating current round them and place a coil, R, of wire in the vertical position, it will turn and come to rest in that position in which it will cut the least number of magnetic lines—that is, in the horizontal position. This will then be a dead point. Now, in order to make the coil, R, go on rotating we must produce a second current at right angles to the first, thus creating a rotary field, but not a true rotary field. This can be done by placing two more electromagnets, B B^1, at right angles to A A^1 (Fig. 2), and so arranging matters that a current is first passed round the coils A A^1, producing magnetic lines in a downward direction and creating a N pole on the top and a S pole on the bottom. This causes the coil R to turn horizontally. Now cut off that current, which we will call No. 1, and pass a second current through the coils round the magnets, B B^1, making B a N and B^1 a S pole. This will cause the coil R to turn through a right angle into the vertical position. Switch off current No. 2, and pass current No. 1 through

* Abstract of paper read before the Institution of Junior Engineers on February 15, 1895.

Digitized by Google

the coil A and then through A^1. The resultant magnetic force now passes upwards from A to A^1, producing a N pole at the bottom and a S pole at the top, and the coil R then moves into the horizontal position. We now repeat the operation with current No. 2, so that B^1 becomes a N and B a S pole; the coil gain takes up the vertical position and thus completes one

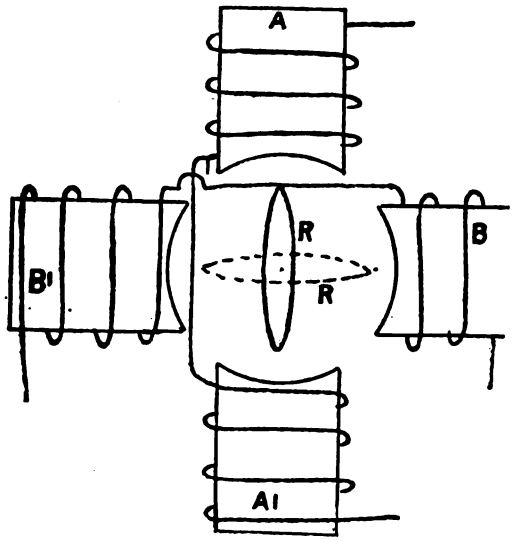

FIG. 2.

revolution, so also has the resultant magnetic force through the four coils. It must be remembered that the current does not rotate, but only the resultant magnetic force. This is exactly what happens with a two-phase rotary field motor, and on a steam-engine would be equivalent to putting the cranks at right angles to each other.

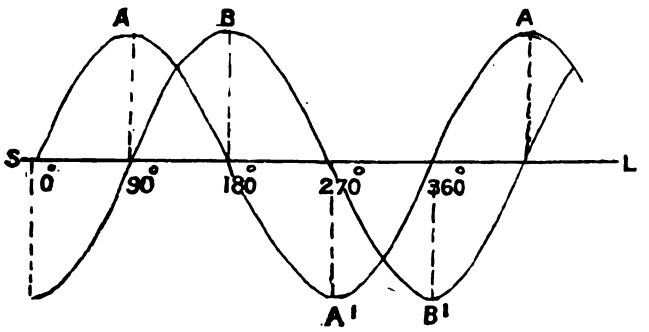

FIG. 3.

Such rotary fields are produced in the generator in the following manner: Instead of passing currents through the four coils, A A^1, B B^1, A^1 A, B^1 B (Fig. 2), a magnet is revolved in front of them. In this case the armature will be stationary, and it is the field that we are revolving, and producing two alternating currents which will differ in phase by a quarter of a period. This can best be illustrated by means of curves, Fig. 3. The straight line, S L, represents the circle through which the magnet passes in front of the coils. The resultant E.M.F. induced in the coil A gradually rises until it has reached the maximum positive value just as the magnet is passing under the centre of the coil, the E.M.F. then begins to die away to zero. At this point the magnet has travelled through an angle of 180deg., and the E.M.F. afterwards begins to assume a negative value. At the point where it crosses the line, S L, there would be a dead point in the motor, were it not that the E.M.F. in the coil B has now reached its highest possible value.

Fig. 1 represents a two-pole single-phase motor. Fig. 2 is a four-pole two-phase motor, the currents differing by 90deg. To build a three-phase generator or motor we must have six coils and six wires, if they are constructed as Fig. 2, giving phase difference of 60deg., or we can construct them with a phase difference of 120deg. by winding the field of the generator continuously round a ring of iron, as in Fig. 4. This is equivalent to joining the three ends of the six coils so as to form a continuous winding, and produces a true rotary field—the armature being a mass of iron plates with copper bars laid in close to the periphery to increase the conductivity, or else composed of sets of endless coils joined so as to form

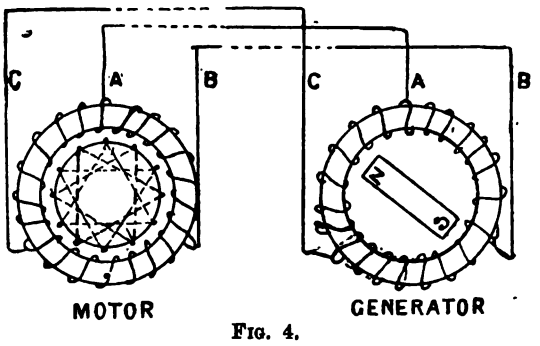

FIG. 4.

a squirrel-cage winding. In order that you may see exactly what takes place in a machine of this type, I have made a model, which was invented by your past-president, Prof. Thompson. Imagine that the two circles are the N and S poles of the field magnet, and that the lines A^1, B^1, and C^1, 120deg. apart, are equivalent to the three lines A, B, C. Now, when the two circles are revolved, the highest E.M.F. is being induced in A and then in coil B and C successively. The field of the single-phase Brown motor, shown in Fig. 5, is wound with thick-wire coils forming three N and three S poles, and it also

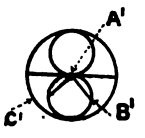

FIG. 4A.

has a set of thin-wire coils forming a second set of poles. The armature is wound in a similar manner, forming three sets of poles of six coils each. In order to make it self-starting, we must have two currents at right angles to each other. This is done by placing a liquid condenser, consisting of plates of iron immersed in a solution of common soda, in series with the fine-wire coils, and thus producing two currents in the field differing in phase by nearly 90deg. After the motor has run up to full speed the condenser and fine-wire coils are cut out of circuit, and there is then a simple oscillating field.

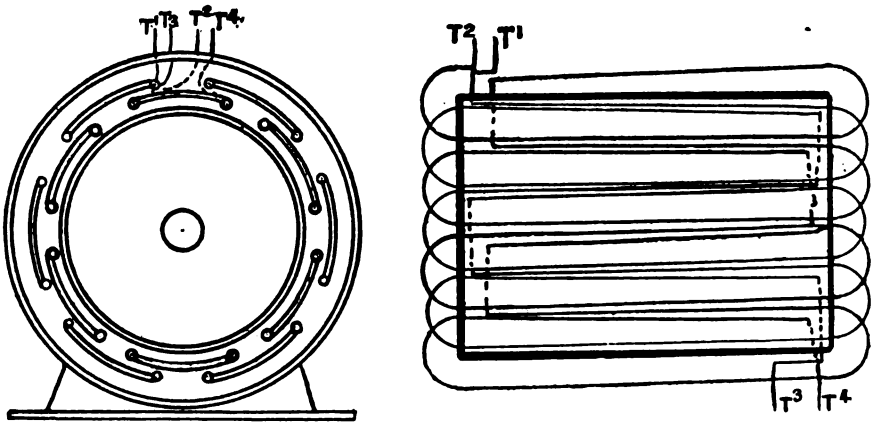

FIG. 5.—End Elevation—Sketch of Winding.

We have already said that the frequency of a generator depends upon the number of pairs of poles upon the field and upon the rate of speed of the armature. Therefore, the speed of a motor will depend upon the frequency of supply and upon the number of poles upon the field. The above motor is designed for a frequency of 100 cycles per second. Divide this by 3 and multiply by 60 and we get the speed = 2,000 revolutions per minute. In practice there is from 3 to 5 per cent. slip to

Digitized by Google

be allowed for. By putting double the number of poles upon the field we should halve the speed. We cannot, however, go on increasing the number of poles indefinitely for both mechanical and electrical reasons.

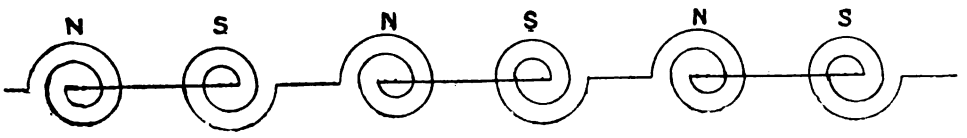

FIG. 6.

Each alternate coil upon the field is wound first right-handedly and then left-handedly, as Fig. 6, or if they are all wound right or left handedly then they must be connected as Fig. 7. The six coils are purposely shown in a straight line, so that the winding and connections can the more easily

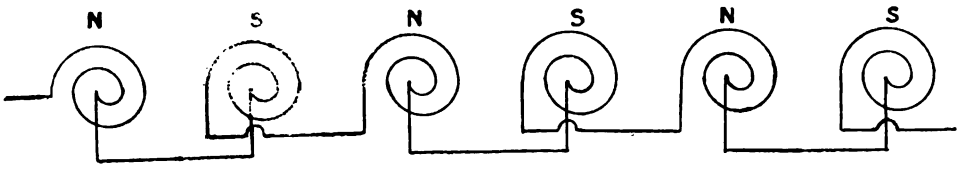

FIG. 7.

be traced. The reason for winding the coils in the foregoing manner is because the polarity of an electromagnet depends upon the way in which the current flows round it. Suppose we have a straight bar, A, of iron and wind it from left to right in a clockwise direction, looking at the left-hand end, and pass a current in the direction of the arrows, then the right-hand end will be the N pole, and the magnetic lines will flow outwards from the N pole. This necessitates connecting the coils so as to cause the currents to circulate as in Fig. 9, otherwise we shall have either all N or all S poles on the inner side of the field, and the resultant induced currents in the armature would flow in opposite directions in each winding, and would thus counteract one another. Fig. 5 represents the winding of the field of this machine. The armature is laminated, consisting of plates of iron having holes stamped out all round the periphery, through which coils of wire are threaded so as to form three sets of coils. One of the ends of each set of coils is taken to a common juncture, and the other three ends are connected to three insulated rings on the end of the shaft having copper brushes bearing upon them. A set of resistances is connected to each brush, and thus in series with each set of coils. The object of these resistances is to prevent the sudden rush of current which would otherwise take place when the motor is first started.

Having briefly touched upon the fundamental principles of these machines, I now propose to give you descriptions of installations where these motors have been successfully applied in practice, and to compare them with other forms of motive power. The first installation is one designed by the writer and applied to the blowing of organ bellows. In this particular instance there were really two organs (an additional organ having been built some 15 years after the first one), each having its own separate bellows and set of mechanism. This very much complicated matters, as it was necessary that the motive power should be divided, so as to be capable of being utilised for either or both organs. To effectually supply air to organs by means of mechanical power it is necessary that the whole of the plant should be completely under the control of the organist, and that everything should as far as possible be arranged to act automatically, as the organist has quite enough to occupy his attention in regulating 60, 70, or even 100 stops.

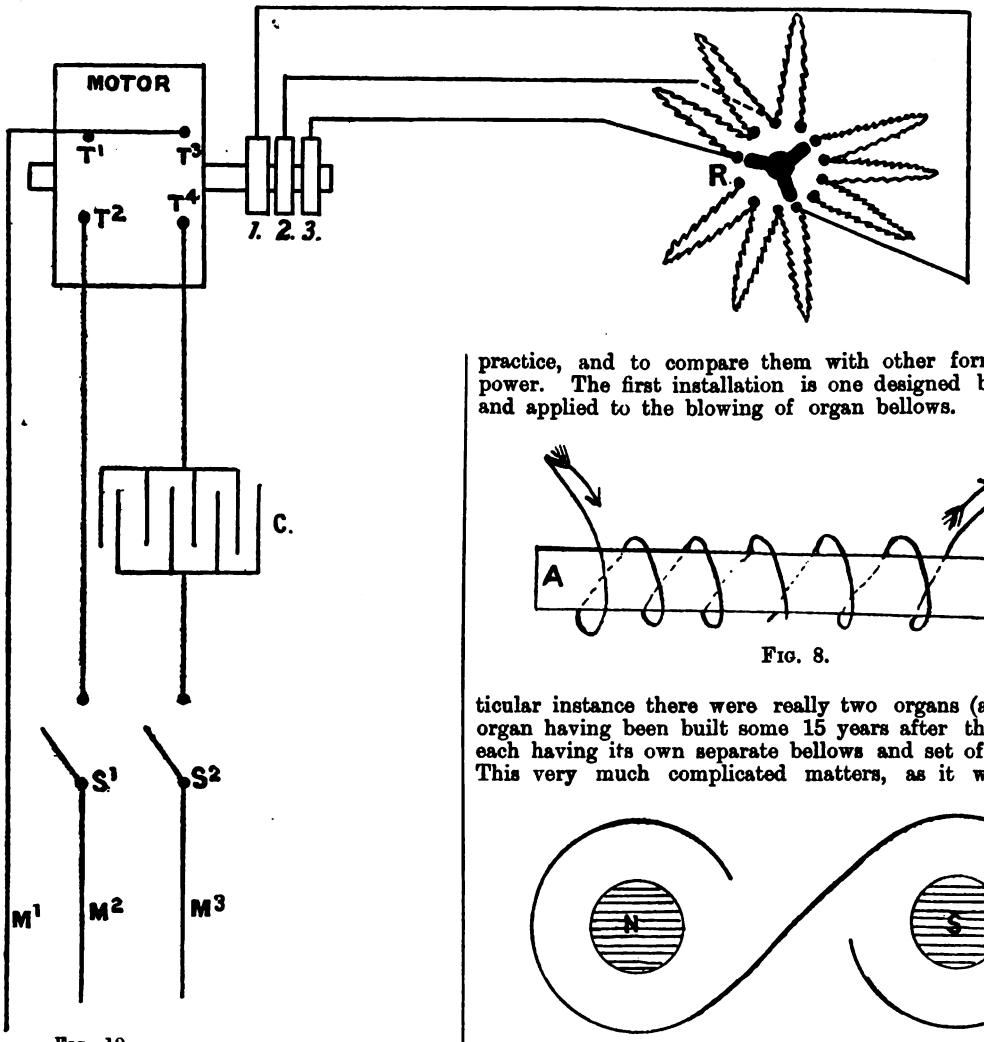

FIG. 10.

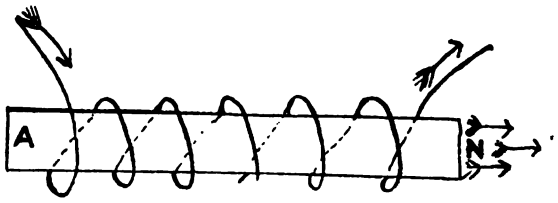

FIG. 8.

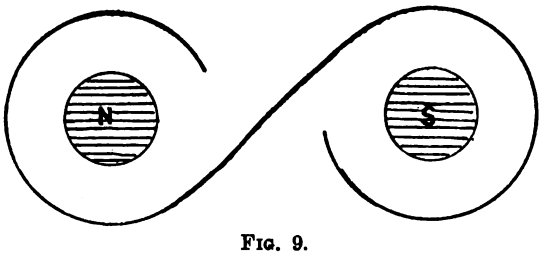

FIG. 9.

Digitized by Google

Up to the present hydraulic power has been chiefly used, as it was most easily regulated, worked smoothly and without noise, and, above all, is self-starting. It has, however, one great drawback. In winter it is not always possible to thoroughly protect the motor from frost, being more often than not placed in a cold, damp cellar.

Gas-engines are occasionally used, driving by means of belts on to fast and loose pulleys connected to the crankshafts. As the windchests are filled they automatically shift the belt from one pulley to another by means of small levers, which only come into action when the windchests are nearly full or nearly empty. The main objections to gas-engines are: (1) they are not self-starting on load; (2) will not work in a confined space; (3) are noisy; (4) require constant cleaning and attention.

With electromotors the case is very different, as they have the advantages all on their side, and, briefly tabulated, are as follows: (1) they are exceptionally economical, as the energy consumed is directly proportional to the work done; (2) they can be placed in any position; (3) they are free from noise; (4) they are self-starting; (5) they are perfectly under the control of the organist; (6) they cannot be frozen out; (7) they require the minimum of floor space; (8) the speed can be varied at will; (9) they can be arranged to act automatically.

Direct-current electromotors undoubtedly faithfully fulfil all

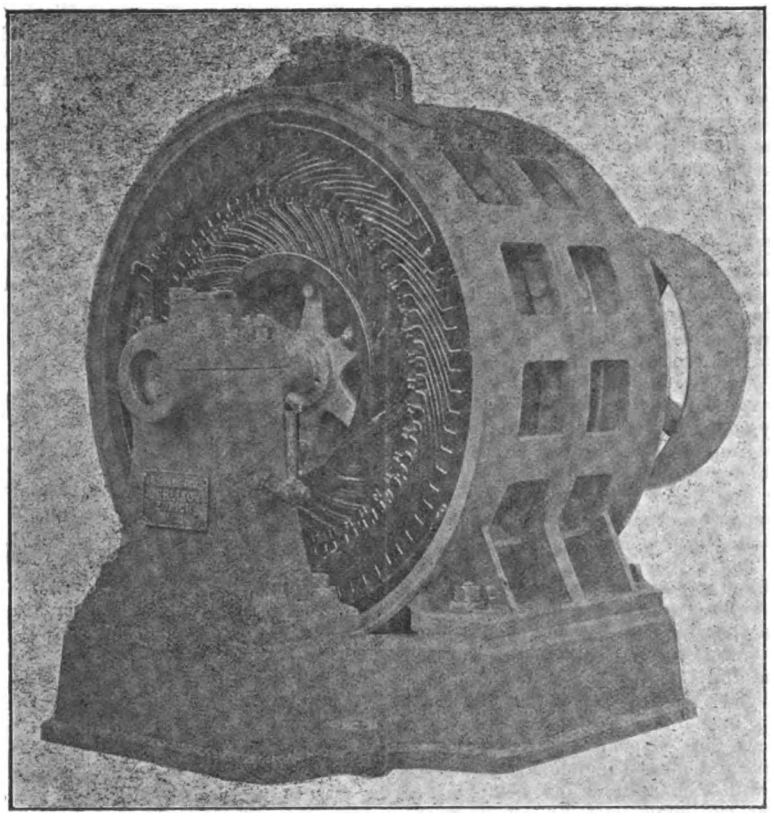

FIG. 11.

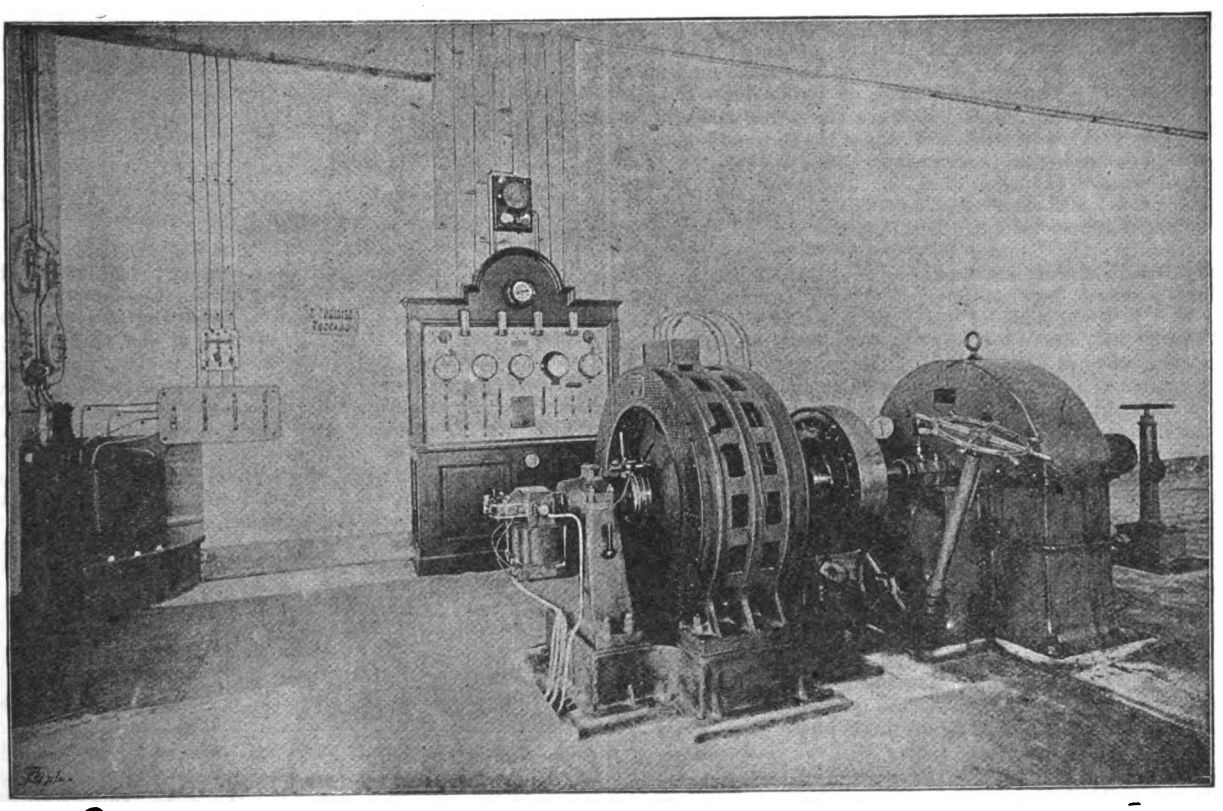

FIG. 12.

Digitized by Google

these conditions, but to-night we are considering the application of alternating-current motors, and in this particular case a single-phase one had to be used. A description of the winding of this motor, with the various arrangements for making it self-starting and for preventing the sudden rush of current, has already been partly given.

The motor is a 3-b.h.p. one, capable of working up to 4½ h.p. for short periods; the speed is 2,000 revolutions per minute; length of shaft over all, 1ft. 8¼in. The lubrication is carried out by means of loose brass rings dipping into oil. Frequency is 100 cycles per second; voltage is 100; starting current about 68 amperes; current at full load, 41 amperes. It is connected on to a worm (which is cut out of the solid), by means of a cone coupling. The wheel consists of 40 teeth, thus giving a speed of $\frac{2,000}{40} = 50$ revolutions per minute to the pulleys. The wheel is keyed to a 1¾in. shaft supported by two adjustable plummer blocks on sole-plates, the 10in. by 4in. pulleys being keyed on to the outside of the plummer blocks, and the whole of the gearing is enclosed in an oil bath. The power is then transmitted by means of two double leather orange tan belts, travelling at 135ft. per minute.

At first sight it may appear strange that the levers were not connected directly on to the wheel shaft by means of cranks, and that a great saving in power and cost would thus have been effected. The chief reason against this was that we have to supply power from one motor to two distinct sets of bellows feeding the two separate organs. It was therefore absolutely essential that each set of bellows should automatically take power from the motor as required, and that when either set of bellows were filled any excess of power should be transferred to that set of bellows which was being worked at the quickest rate. Imagine that by some means the power of the motor has been divided into three parts. One third works the first bellows, the second third works the second bellows, and the last third dodges backwards and forwards. Had the belts, clutches, and shafting been dispensed with, two motors would have been required, two sets of gearing, a double set of switching and starting gear, and altogether the arrangements would have been more complicated and not so elastic or so automatic as the above. The supply of energy is taken off the mains of the Metropolitan Electric Company, and separate transformers have been put in for the lighting and power. This was done so that the switching on and off of the motor would not affect the pressure at the lamp terminal.

The connections to the motor are shown in Fig. 10, where the mains, M^1, M^2, bring in the supply. Main M^1 is connected on to terminals, T^1, of the thick-wire coils and, T^2, of the fine-wire coils. Main M^2 is connected on to the thick-wire terminal, T^3, having a switch, S^1, in circuit with it at the point P, a branch is teed on to main M^2 and is connected to a condenser, C, through switch S^2, and then to the remaining fine-wire terminal, T^4. The two windings of the field are thus in parallel with each other; 1, 2, and 3 are the three rings upon the armature shaft connected to the ends of the three sets of coils, and having brushes bearing against them connecting the different resistances, R, into the three circuits. The resistance, R, has three steps to it, each step being cut out of circuit by a three-way laminated copper bridge. The motor is started by closing the switches S^1 and S^2, and putting the whole of resistance, R, into circuit with the armature; thus the motor for starting is a two-phase machine, because the current going through the condenser and fine-wire coils of the field is in advance nearly a quarter of a period over the current through the thick-wire coils. When the motor has attained full speed S^2 is opened, cutting out the condenser; and the resistance, R, is then gradually cut out of circuit until the coils on the armature are short-circuited. As these five operations would cause the o ganist a good deal of bother, they have been arranged to actr automatically, so that he only has to pull a small lever round through a third of a circle, and by so doing closes and opens the various switches. The time occupied is not more than 20 seconds.

An electrical contact arrangement has also been devised, and fitted to the shaft of the motor, so that when the motor has attained full speed a ball flies out and makes contact with a brass plate. This causes an indicator on the keyboard of the organ to drop, warning the organist that it is time to pull the lever of the switch right over, cutting out the condenser and resistance, and as the latter is cut out the circuit to the indicator is broken, so that the battery does not run down. This is, I believe, the first single-phase, self-starting motor put down in England of over 1 h.p. Switzerland is, however, the country where we find alternating motors working to perfection. At the locomotive and boiler works of Messrs. Escher, Wyss, and Co., of Winterthur, they have something like 900 h.p. on the three-phase system, the generators being worked by turbines at a distance of 16 kilometres = 9·936 miles. The large tools are worked by separate motors of 60 h.p. and 70 h.p. The smaller motors, of 3 h.p. and 5 h.p., are coupled up to shafting by means of belts, and work four or six small tools, such as lathes, drilling machines, etc. In the old works driven by steam and shafting, they required 2,000 h.p. to do exactly the same amount of work as the present electrical plant of 900 h.p. In calculating the enormous saving thus effected the amount of floor space saved must also be taken into consideration.

The Oerlikon Electrical Works have also a very perfect installation. I am able to show you a few photographs taken direct from the installation by Mr. Bathurst. The generator has a frequency of 48 cycles, pressure 50 volts, and generates three-phase currents. These low-pressure currents are taken into transformers with oil insulation; the pressure is transformed by them up to 13,000 volts. It has then to traverse a distance of 15 miles to the works, where it is transformed down again to 190 volts. Fig. 11 shows a 40-h.p. three-phase motor, with eight poles, running at 750 revolutions and 50 cycles.

In all these installations the great simplicity of working cannot but be noticed, as the motors have neither brushes nor commutators, which, as most of you know, are the parts which give the most trouble and require most attention in direct-current motors. They can also be safely overloaded as much as 50 per cent. without any fear of breakdown. It thus becomes next door to impossible to burn them out.

I have had a sheet of designs printed for your inspection to-night. Fig. 12 is the interior of the generator-room, showing the turbine, generator, switchboard, transformer, and general arrangements. Fig. 13 is the interior of the generator, showing the manner in which the coils are connected and the ease with which they can be got at for repairs. The field is separately excited by an exciter placed upon the end of the shaft, has 12 poles interlocking with each other, the winding being taken between the poles and held in position by them.

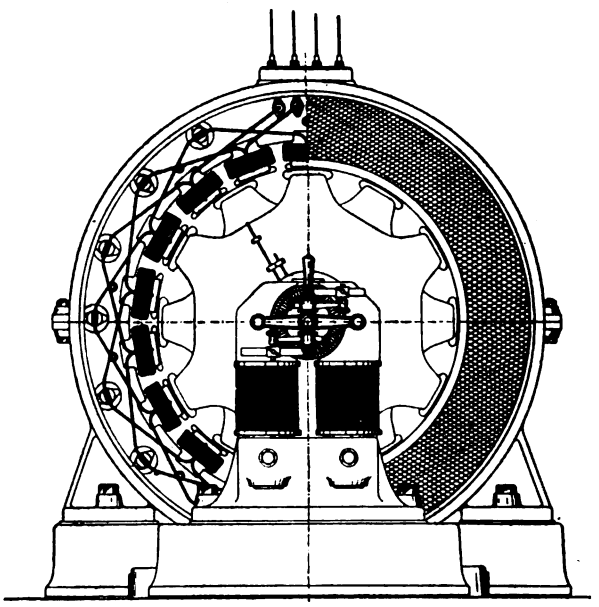

FIG. 13.

I have also for your inspection various machines of 3 h.p., ¾ h.p., and 1-10 h.p. They are of the Oerlikon make, and have special starting arrangements, consisting of a small transformer placed in circuit, with one set of the windings taking a small current at 100 volts from the mains, and giving a relatively large current at small voltage to the motor. A resistance is placed in series with the second winding. The rotor, or armature, consists of iron plates having copper bars close to the periphery, as previously explained. In conclusion, I have to thank Mr. Hirst, the General Electric and Oerlikon Companies, and Messrs. Joel and Bowen for their kind assistance and for the loan of these machines.

CANADIAN MICA.

The samples of Canadian mica on exhibition in the Canadian Section of the Imperial Institute, Imperial Institute-road, S.W., to which we referred in our last issue, comprise three varieties—viz., brolite (or black mica), phlogopite (or amber mica), and muscovite (a potash mica, usually white). Prior to 1890, Canadian mica was chiefly worked to supply the stovemaking trade, but owing to the demand which has recently arisen for the mineral for electrical purposes, the mica industry of Canada has developed largely during the past five years. Most of the Canadian mica is mar-

Digitized by Google

keted in the United States, where the amber variety is used by manufacturers of electrical machinery. The bulk of that employed by the Edison General Electrical Company is Canadian mica of the amber-coloured variety. The value of the total output of Canadian mica in 1889 was 28,718del., as compared with 75,719dol. in 1893. The value of the total exports was 30,597dol. and 70,081dol. respectively. The samples recently sent to the Imperial Institute are all from the province of Quebec, and were obtained chiefly from deposits occurring in the Laurentian rocks of the valley of the Gatineaw River. They are supplied by Messrs. Powell and Clemow, W. A. Allan, Cascades Mica Company, and Vavasour Mining Association of Ottawa, and Mr. G. B. Hall, of Quebec.

NEXT WEEK'S NEWS TO-DAY.

Mr. Justice Mathew will to-day (Friday) take his seat as a commercial judge, and will continue to sit for the despatch of commercial business.

Engine, boiler, and dynamo makers will be interested in learning that circulars have been issued to 200 iron firms containing the draft scheme of a projected Midland Iron Trade Association.

The jury who yesterday returned a verdict of accidental death in the case of the City lift fatality evidently had in mind the use of electric power when they added a rider to the effect that all lifts used for passengers should have some automatic arrangement by which similar accidents may be prevented in the future.

Lord Rayleigh will commence a series of six experimental lectures at the Royal Institution on Saturday on "Waves and Vibrations." A duplicate apparatus for the production of argon having been fitted up in the physical laboratories in Albemarle-street, Lord Rayleigh will be able to show some of this much discussed "element" during his lectures.

The Home Secretary in the House of Commons yesterday evening stated that he hoped to introduce a Bill dealing with shot-firing in coal mines, and that special attention would be given to the recommendations of the Royal Commission on Explosions from Coal Dust in Mines. It will be remembered that among the recommendations of the latter is the advice that shot-firing by electricity should be more generally adopted.

INSTITUTION OF ELECTRICAL ENGINEERS, Feb. 28.

MR. R. E. B. CROMPTON (President) in the chair.

At last night's meeting of the Institution the following candidates were balloted for:

Foreign Member.—Henry Fleetwood Albright, 5304, Lancaster-avenue, Philadelphia, Penn., U.S.A.

Associates.—Edwin H. Barton, D.Sc. (London), University College, Nottingham; Captain F. Baylay, R.E, School of Military Engineering, Chatham; Nelson Dadge, 18, Cecil-court, Charing Cross-road, W.C.; Lieut. A. H. Dumaresq, R.E., School of Military Engineering, Chatham; Frank Burridge Foy, St. Vincent, Cape de Verde Islands; Lieut. M. E. R. Maunsell, R.A., Royal Military Academy, Woolwich; Herbert Nash, 19, Palace-gardens-mansions, Notting Hill Gate, W.; William Llewelyn Phillips, Cedar House, Romilly-crescent, Canton, Cardiff; Eustace Thomas, B.Sc., the Technical College, Leonard-street, Finsbury.

Students.—Frederick John Caley, 8, Barclay Park-terrace, Knott's Green, Leyton; Norman Endacott, the Technical College, Leonard-street, Finsbury; Arthur Thomas Gordon-Smith, Faraday House, Charing Cross-road, W.C.; Reginald Charles Harpur, Faraday House, Charing Cross-road, W.C.; Hugh Godfrey Nicholson, 346, The Cliff, Higher Broughton, Manchester; Edward Fairlie Watson, 4, Priory-road, Kilburn, N.W.; Norman James Wilson, 28, Trafalgar-square, South Kensington, S.W.

Before the discussion was resumed on Mr. W. B. Sayers's paper on "Reversible Regenerative Armatures and Short Air Space Dynamos," the author further explained certain formulæ which at the meeting on the 14th ult. he had placed on the blackboard, but which he thought had not been well understood, as they had not appeared in the printed paper.

Prof. S. P. Thompson congratulated Mr. Sayers on the progress he had made. There was a main line of thought in the work. The author wanted to get over the difficulty of sparking at the brushes, and then to employ copper and iron to greater advantage. The original way was to give the brushes a forward lead so that the reversals might take place. Various other ways had been tried. One had been to employ an air flash to blow out the spark. Mr. Mordey had created a separate magnetic field for the same purpose. Both Messrs. Esson and Swinburne had advocated auxiliary poles. Mr. Sayers had done it by notching. Then there came the method known as Prof. Ryan's of winding a series coil over the armature, or cross-compounding. The objection which had been raised to Mr. Sayers's method in his previous paper, that he could only revolve in one direction, had now been removed. The speaker then proceeded to explain what he took the nature of the author's dynamo to be. The armatures now proposed were different from those of two years ago, being of the drum construction. He wanted to know if anyone had any experience of running any of the Hutin-Leblanc machines (which we described and illustrated some time ago). He had had no experience of the latter, but he described it with the assistance of blackboard diagrams. Mr. Sayers had mixed up slotted armatures with tunnel armatures, whereas they were quite distinct. The difficulty in the slotted system was that the insulation was difficult, and he would like to know how Mr. Sayers had carried it out. In the United States there was not 5 per cent. of the dynamos made which had smooth armatures. He did not know under what circumstances anyone would want a dynamo to run in both directions save in the case of railway train lighting. The machine weighed 67lb. for each horse-power when run as a motor, but he thought that a machine could be made for less. He thought it inadvisable to put all the copper in the armature.

Dr. du Riche Preller referred specially to the matter of weight, but a reduction in weight did not necessarily mean a reduction in price, and, for instance, where a motor was used for traction purposes it was inadvisable to make it too light. The author's 80-kilowatt machine weighed 3½ tons, or 100lb. per kilowatt. Mr. C. E. L. Brown's 60-kilowatt machines weighed 2 7 tons, or 90lb. per kilowatt- The Brown 90-kilowatt machine was 90lb. The ordinary Brown 80-kilowatt machine was 117lb., and this could have been reduced to 100lb., but the designer had refrained from doing so for practical work. The Thury dynamos of the Geneva Electrical Company were about 110lbs. per kilowatt. Mr. Sayers claimed an efficiency of 96 per cent. That might be a test efficiency, but he doubted if it would be obtained in practice.

Mr. Evershed followed with a mixture of jokes and practical information. The only real difference in the ways of sparkless commutation was in obtaining the induction. He thought the labour of winding the armatures was increased where the weight was diminished. Mr. Sayers had devised an admirable, though rather complicated way of reversing. With reference to a drawing on the wall of a dynamo by Mr. Ravenshaw, he had held in theory that there must be sparking somewhere but he had seen it working and found absolutely none. Mr. Sayers was the only man who had had the courage to deal with the question of improving continuous current dynamos. It might not be the best method, but it would do.

Mr. R. E. Crompton, in closing the discussion, remarked that there was rather a tendency to undervalue the author's invention, on the ground that the plain slotted armature was sufficient. Dr. Preller had compared the Sayers machine with that made by Mr. Brown, but the conditions on the Continent and in England were entirely distinct. If Mr. Brown was called upon to produce a machine like those made in England, with the high efficiencies of 96, and even 97, per cent., he would make them heavier.

Mr. W. B. Sayers, in replying to the discussion, contended that if the proportions he had given were carried out, there would be no heating whatever of the pole-pieces or any measurable loss of power as contended by Mr. Anderson and others. With regard to Dr. Preller's observation concerning slotted and tunnel, the reason he had used the terms was because he had merged one into the other, as was explained on the blackboard, and he had unconsciously slipped into the way of calling them by that name. Dealing with parallel running, the speaker said that the coupling of direct current machines in parallel did not depend upon whether they had compound or forward coils, but upon the characteristic. If the machine had a falling characteristic the arrangement was quite stable. Discussing the question of weights as set forth by Mr. Anderson, Mr. Parshall, and Dr. Preller, he stated that on comparing his type of machine with those described by those gentlemen, and with those of other makers, he found that the ratio was as 5 to 8. The Brown machine was of the four-pole type. If he, the author, made four-pole machines, their weight would be approximately half that mentioned in the paper. Treating of Mr. Mordey's remarks in regard to certain words, the author regretted that he had used various terms to express commutator segments. The doubling of the commutator coil allowed of the use of the poles referred to on the wall diagrams; their use was to increase the effectiveness of the commutator coil to the extent of something like 75 per cent. Referring to the reversing pole-pieces, the author stated that they largely increased the output of the machine for a given weight. Some speakers were under the impression that the main object was to get a regenerative action from the armature with a view to keeping up the voltage, but the chief advantage was that enough current could not be put on the armature to destroy the reversing field. Having dealt with some other matters touched upon in the discussion, the author decided to give the remainder of his reply in writing for publication in the *Journal*.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

CENTRAL-STATION LIBRARIES.

If we might venture to make a suggestion which certainly to a limited extent concerns ourselves—and, so far, may be thought to be biassed—it would be that all companies and authorities owning a central station should provide the employés with a good technical library. The men themselves ought to regularly buy their technical periodicals as each individual chooses, but it is too much to expect some of the younger ones or apprentices to equip themselves with a first-class technical library. And yet no man, be he stoker, manager, or director, ought to be without the reach of such technical books. The same may be said of members of local authorities. They should be able to check statements made to them by reference to standard authors, and if our idea of a technical library at each central station was carried out there would be no difficulty in doing this. The knowledge required in order to carry out almost all central-station work is such as ought to be easily attained by any person of average intelligence. The men employed about the engines and dynamos ought to have some knowledge of mechanical engineering, and be able to carry out many of the little repairs that are often made an excuse for shirking work. Simple books on the steam-engine, the boiler, and the dynamo ought to be at hand and be studied. The men should know something about shafting, belting, lubricants, and lubrication; should have some little knowledge of the theory of steam, the calorific value of fuels, the various ideas about stoking, feed water, condensing, the impurities likely to be met with in the water used for the boilers, and the best way to counteract the effect of such impurities. In order to obtain this information, the men who have not had the advantage of any special training should be induced to attend the science classes held under the auspices of the Science Department or the City Guilds Institute. Men should be encouraged to look and work upwards, and the only way to do this is to obtain knowledge. The old axiom still holds good, "knowledge is power," and will be so long as this world endureth. Then, while we should strongly urge every man to obtain a small technical library of his own, we cannot but recognise that often his means are limited, and he cannot obtain what he would like. It is here the works' library should come in. Our views, of course, are just as applicable to any other industry as the one we are appealing to at the moment. Many factories, we are glad to know, have both library and reading-room. These ought to be extended to every works. The success of such libraries depends very much on the librarian. In some places the books are hardly ever consulted—the men are not readers, is the excuse. Well, few men are readers after they have left the hands of the schoolmaster. More is the pity. But they can be influenced for their own good. They can be led to see that the difference between themselves and the men in the rank next above is a pure question of knowledge. In large works where a number of apprentices are taken, principals ought to look after

Digitized by Google

the manual experience and dexterity of those placed in their charge, and to see that they have opportunities of acquiring the requisite technical knowledge to move upwards in the profession they have chosen. This view of the case is fully recognised in several works. In electrical works we may mention one of the earliest in Messrs. Crompton and Co., who obtained the services of Prof. Fleming as lecturer some years ago, and who have more recently obtained the services of other lecturers, so as to give their pupils the benefit of theory as well as of practice. But even in these works we venture to think the necessity of a technical library has been overlooked. Most of the apprentices or pupils, or whatever name they go by, probably obtain the best books upon the subject directly before them, but where the individual effort is most likely to fail is in obtaining the books which only indirectly bear on the subject. The calorific value of various fuels will not appear as of any value to the pupil in an electrical works, but he may have charge by-and-by of a central station and have a large voice in the purchase of fuels, when he will find that even coal differs and requires a little attention for economic purchase. It was our intention at the outset of this article to suggest various means by which a technical—and within this term we include a reference—library might without difficulty be obtained. With one exception, however, we shall reserve our remarks on this head—the exception being in reference to fines. Almost all works have a custom of imposing fines for certain lapses of duty. These fines might be used beneficially by using them for the purchase of books for the library. But we are in hopes that those most interested in the matter will favour us with their views on the subject.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

TESTING INSTRUMENTS.

SIR,—Referring to your notice of recent catalogue of electrical testing instruments, my attention has been called to a description therein of a galvanometer designed and patented by me in 1891 to 1892, and named by permission "The Ayrton-Mather Galvanometer." I note that the illustration and description in that catalogue correspond to my list No. 2 of 1892 (No. 76), and would point out that the detail and arrangement of the instrument in question are covered by my patent No. 4,276 of that year. I regret that the firm issuing this list should copy the original designs of other makers.—Yours, etc.,

ROBT. W. PAUL.

44, Hatton-garden, E.C., February 27, 1895.

FATAL ACCIDENT AT BRISTOL.

SIR,—A most deplorable accident occurred at one of the sub-stations of the Bristol Corporation electric light works on Monday afternoon, February 25, resulting in the death of a linesman.

The deceased, Robert Coleman, had been engaged by the Corporation as a linesman for 12 months, prior to which he had been employed by Messrs. Siemens Bros., National Telephone Company, etc., and was a thoroughly sound and good man in every respect.

Coleman had been entrusted with the keeping in order of the sub-stations for some months past, and at the time of the accident was wiping down the high-tension board with a cloth, and was wearing an indiarubber glove on his right hand for the purpose. Whilst so working he looked away to speak to another person present, and the back of his left hand accidentally came in contact with a fuse terminal, he thus making contact to earth with the 2,000-volt mains.

Every effort to restore him was without avail; a medical man was on the scene within two minutes.—Yours, etc.,

H. FARADAY PROCTOR.

Bristol Electric Light Station, February 27, 1895.

P.S.—At the inquest held at 4 p.m. to-day (Wednesday) a verdict of "accidental death" was returned.

REVIEWS.

What is Heat? A Peep into Nature's Most Hidden Secrets. By FREDERICK HOVENDEN, F.L.S., F.G.S., F.R.M.S. London: W. B. Whittingham and Co.

Oh, dear! We do like a good old heterodox person, but we do not like an heterodox person that is seemingly unconscious of twisting everything topsy-turvy to suit his own purposes. Mr. Hovenden is one of these. In this book he falls foul of the mathematician in the first place, and because he cannot understand the conventions of simple arithmetic, characterises all mathematical science as founded on fundamentally wrong principles. Even such a petty thing as $1 \times \frac{1}{2} = \frac{1}{2}$ beats him, and four pages later on he grandiloquently writes: "Now, reader, can your *mind* understand that addition is subtraction; in other words, that 6 objects multiplied $\frac{1}{2}$ times become 3 objects ($6 \times \frac{1}{2} = 3$)?" That is what we term wresting mathematical symbolism and methods to illustrate what they don't mean. Any schoolboy would laugh at the teaching and tell the teacher that $6 \times \frac{1}{2}$ was simply another way of putting the question, What is the half of six?; or, taking the half away from six, what remains? Or, again, if they must retain the addition form Mr. Hovenden so continually puts forward as multiplication, they would transpose his question and say, How many whole objects do six halves make?

Yes, Mr. Hovenden starts wrongly. We do understand much, if not all, that he says we do not, but, of course, we do not translate in the form he puts forward. Talking about zero again on page 15, he says: "These very facts show the artificial condition of things." Of course they do. Zero can be what you please to make it. Its position on the Centigrade or Fahrenheit scale has nothing to do with the fundamental principles of mathematics, or being different on each scale makes neither of them incorrect. To attempt, however, to refer to the mathematical fallacies underlying Mr. Hovenden's description would take as much space as his statements do, while to criticise and explain them would require a volume.

But though we deride Mr. Hovenden's statements in regard to mathematics generally, we have much in common with him when he goes on to discuss the fault of interpreting Nature by means of mathematics—symbols, formulæ, and suppositions or assumptions—the result being usually in the form of K (known facts), where K is a constant which has to be determined for each separate substance.

We know that Clerk Maxwell in his later days preferred Faraday's experimental, and what we may term physical, path of investigation rather than pure mathematical induction. Here we agree especially with the quotations from Dr. Lodge—which are numerous—though we doubt Prof. Lodge would agree with the author's remarks and deductions.

In Part II. the author deals with the kinetic theory, and here, among much that is right and very well stated, he gets into wrong grooves and thus draws wrong conclusions. After quoting from "Chambers's Cyclopædia" about the atomic theory, he says: "According to this view there is, therefore, *no permanent contact between the objects of which matter is composed—atoms and molecules*; there can be no adhesion or cohesion, because this implies permanent contact."

Digitized by Google

It implies nothing of the kind, except as understood for the purposes of our author. We may just as well understand that cohesion allows a molecular movement as that it implies molecular contact. Again, there is not necessarily molecular impact during molecular motion. Says our author, page 56: "According to this view, the particles are never still—their motions are *eternal* in temperate or tropical climates." Is there anything strange in this view, though we are not concerned to bolster up the theory of continued molecular motion? All that we are concerned about is to maintain there is no difficulty in following the reasoning of physicists in this direction, and unless Mr. Hovenden has a better theory, the physical concepts about atoms and molecules form a good working theory. But we must hurry on, simply but firmly contending that all physicists worthy the name and approaching the highest ranks admit their theories to be tentative. They are better than what has gone before, and will serve as a stepping-stone to what is to come after—at least, such is our idea gained from hearing the men speak and talk many a time. We say such is our idea of the views of Kelvin, Rayleigh, Rücker, Dewar, Lodge, FitzGerald, Glazebrook, and many others.

Up to page 113 we have only got criticisms of others, and argument as if physicists assumed infallibility for their theories. At this point we have impressed on us that "matter is built up of atoms," and weight is due to gravity acting. We thought a few pages before that we were going to have an explanation of what gravity is—but not yet.

The theory of Mr. Hovenden with regard to heat is that it is merely a question of "ether" absorbed. Objects which have absorbed equivalent quantities of ether are at the same temperature. If one object, however, has absorbed more than the other, it is hotter; if less, it is cooler. Although we fancy to have read or heard of phlogiston or a phlogistic theory in times gone by, this seems to be a recrudescence of something similar, only here the "ether" does duty as the heat and probably life-giving substance. We would not have missed reading this book for a considerable prize, for there is much in it we look upon as good and true, although, as is seen, we cannot agree with the author in his denunciation of mathematicians and physicists. Many of his experiments are simple, beautiful, and instructive. There is one fault we must refer to—the constant iteration of the words "impossible," "absurd." Scientific men have concurred in theories he applies these words to, so that it is possible to obtain such "concepts." We must also suggest that in this book are many statements, which are not proofs, and the author is as dogmatic as any of those he criticises. We had marked many passages for quotation and comment, but must content ourselves with a small portion. On page 119 the author says: "'Heat' and 'electricity' are words or terms expressing the reactions caused by the absorption and flow of an *incompressible* fluid passing *into and through* the atom or molecule. This fluid we will call *ether*; it is, we shall presently demonstrate, easy to be seen. Most likely it is a compound fluid." On pages 134-143 he describes the apparatus and experiments by means of which he says you can see this "ether," but, as a matter of fact, the experiment proves nothing. The author says, there you see the ether—but it is statement, and nothing more. He assumes that a heated red-hot iron rod has taken up ether, and in the experiment says that is ether. Do we want any artificial apparatus to see this antigravitational action? It is analogous to the haze on a hot summer's day which the lazy hammock swinger sees gravitating upwards, yet there certainly are plenty of beautiful phenomena in these experiments. In reading many of these experiments, we continually ask what part does temperature play in them? Even hot air will antigravitate. But enough. This book contains much that is interesting, much that ought to lead to thought, much that is true, many very excellent and instructive experiments, but it at the same time makes assumptions quite as remarkable as any made by mathematicians; it makes statements and assumes they are proofs; it abuses physicists as promulgating innumerable concepts which are not to be understanded of the people, and are stated to be absurdities; the conclusions and explanations are often glaringly contorted, and yet with all this it is well worth reading, if only to see how easily it is to err. Such books do good if studied in the right way, but it must be with an open mind. We know not whence the next best theory is coming, and although Mr. Hovenden has, we think, failed to prove his point, he has most certainly shown how easily existing theories can be attacked, their frailties and weaknesses made plain. Mr. Hovenden is a scientific heretic, but we must not forget, as Mr. Andrew Lang points out in the *Nineteenth Century* for February, that "heretics have in a certain small proportion of cases been in the right."

The Electric Current: How Produced and How Used. By Prof. R. MULLINEUX WALMSLEY, D.Sc., F.R.S.E. With 379 illustrations. Cassell and Co. Price 10s. 6d.

Electricity in the Service of Man: A Popular and Practical Treatise on the Applications of Electricity in Modern Life. By R. WORMELL, D.Sc., M.A. From the German of Dr. A. R. von Urbanitzky. Revised and enlarged by R. Mullineux Walmsley, D.Sc., F.R.S.E. With more than 950 illustrations. Cassell and Co. Price 10s. 6d.

We have placed the larger and earlier issued treatise in the second position, inasmuch as we have referred to it on more than one occasion before This is the third edition, and has been made much better by the care and attention of the reviser. It partakes very much of the character of a cyclopædia—trying to describe everything—and as the description is good, and the illustrations numerous, the book should appeal to the popular taste, which likes to dip a little into many things and obtain a superficial knowledge of various subjects without much trouble, or desire to sift the matter to the bottom. The first-named book, however, is of a different character, though retaining somewhat of the popular style. It is well written, and should strongly appeal to students who desire to make themselves acquainted with electrical matters. It is a general rather than a special treatise, inasmuch as it treats more or less lengthily the whole of the prominent applications of electricity. The greatest attention and space, however, is paid to the application of light and power. The work commences with a short historical account of the subject, and then we have described the methods of producing electricity, with descriptions of primary and secondary batteries. We are glad to see the student's attention so carefully directed to "the thermal values of the chemical reactions that take place in the cell" (pp. 40, 44-49). Chapter IV. brings us to magnetism, the earlier paragraphs in the chapter being historical and descriptive of various simple reactions. It is not our intention to discuss at any length more than one or two points whereon we differ with the author, for we think that on the whole this is one of the best books that have ever been written for the general student. But upon one or two points we must have a say, in that we think the explanations wrong. On pp. 99-100 we get the following illustration and description:

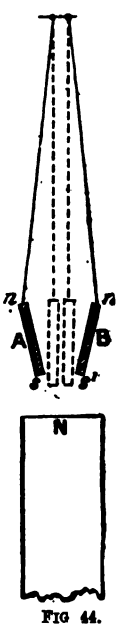

FIG 44.

"**Magnetic Induction.**—That a magnetic body placed near a magnet is for the time being polarised, and itself a magnet, can be shown by a number of striking experiments, from which we shall select one or two. One of the simplest is the following, due to Gilbert: A and B, Fig. 44, are two short pieces of soft iron suspended by long threads, as shown; before the magnet pole (N) of a permanent magnet is brought near to them, they hang side by side in the position shown by the dotted lines. But when either pole—for instance, the north-seeking pole (N) of a powerful permanent magnet is brought underneath and near to them—they assume the position shown by the full lines. Gilbert explains this action by saying that the two ends of the little pieces of iron nearest to N become poles similar to one another, but dissimilar to N, whereas the farther ends become similar poles to N. We have indicated this state of affairs in the figure by the small letters, s, n, s^1, n^1. Now, as the magnetic law is, that like poles repel, we have s and s^1 mutually repelling one another. Hence the little pieces of iron take up the position figured. That the ends nearest N are of unlike polarity to N is shown by the attraction between them and N."

Digitized by Google

Now, although the explanation given and hitherto agreed to by almost every writer is of great antiquity, it is absolutely incorrect. Writers have followed each other like sheep, and we do not hesitate to say that not one of those who have quoted or given this explanation ever stopped to consider its correctness. There is no attraction and there is no repulsion between the ends of A and B. They simply arrange themselves in the direction of the lines of force of the magnetic circuit. They have no influence the one on the other, as can easily be proved—thus:

Take B away and only have A remaining. As soon as it is brought within the influence of the powerful permanent magnet, as explained above, it takes up the position shown by the full lines. There can be no influence from B, because B is not there. A takes up the position shown by the full lines, because it is under the directive action of the lines of force of the magnet. Similarly, take A away and let B remain. Under the influence of the magnet, B takes up the position shown by the full lines, and for the same reason. Is it not superfluous to bring in the idea of attraction and repulsion upon one another when the position taken is due to the directive action of the lines of force of the magnet? There are no mutual attractions or repulsions between A and B, and no other actions than between any two pieces of the magnet itself similarly placed. A and B, when constrained as in the experiment, take up a position in which as many lines of force traverse the pieces of iron as possible; if unconstrained, they would close up to the magnet, the tendency being, as is well known and understood by Prof. Walmsley, to shorten the magnetic circuit. Numerous experiments are reproduced in books year after year, and by author after author, with a totally incorrect explanation, which shows that "human nature is human nature," after all, and most of us are at times too lazy to think. At any rate, we hope to have knocked the bottom out of this particular explanation, or to be shown that the experiment suggested by us is wrong. We are pretty sure that Prof. Walmsley will agree with us, otherwise it will be difficult for him to reconcile his explanation of the action of the magnetised needle, page 132, with the description on page 100. The remaining part of this chapter is for the most part excellent. In fact, wherever Prof. Walmsley is condensing, summarising, or explaining the facts and theories propounded since the birth of the applications of electricity to lighting, power transmission, telegraphy, or telephony, he is at his best. These facts and theories are at his fingers' ends, and although we may not always agree with the latter, there is no doubt about the author's mastery of the subject or of the admirable and simple way in which he expounds it. This chapter on magnetism should be read and studied attentively. But our space is rapidly running out, and we have only referred to four chapters. The following chapter relates to the thermal production of the current, and concludes Part I. of the book. Part II. deals with the "Laws of the Electric Current," commencing with the discussion of conduction, then of chemical and thermal action; followed by the laws of magnetic action and a long, carefully written chapter (IX.) on electrical measurements. The larger part of these chapters is necessarily not new, but whatever is said is well put. We next come to the discussion of alternate currents, and here again the author is at his best. It is a modern subject, and we know of no better descriptive summary in any text-book than this of Prof. Walmsley. Part IV., commencing with Chapter XI., and consisting of four chapters, is intensely practical, dealing as it does with the industrial applications of electricity: first, the applications of the chemical effect; secondly, of the thermal effect; thirdly, of the magnetic effect; and, lastly, of the transmission of power. Here, of course, we get information upon electrolytic work, upon lighting, upon telegraphy and telephony, and upon transmission. We should like to have dealt at some length with some of the paragraphs, but on the whole we think the author has done well both in selection and in rejection. The illustrations are numerous and good. Indeed, the book is not only a credit to the author, but also to the publishers, and we trust will find its way into the hands of every student.

LONDON COUNTY COUNCIL ELECTION.

VOTE FOR THOSE WHO SUPPORT MANUFACTURERS AND CONTRACTORS.

The County Council election will take place to-morrow (Saturday), and don't you forget it. A few words on the subject of the election without entering into party questions may be opportune. The contest between the "Moderates" and the "Progressives" will be very keen, but bear in mind one important fact. The L.C.C. is endeavouring to dispense with the services of contractors in every possible way. It has started operations in the direction of sewering, building, road-making, painting, and decorating, etc., and the reports of the Works Committee presented to the Council show that the work already carried out by them has cost from 25 to as much as 50 per cent. more than either the estimated expenditure or the amounts at which contractors had previously tendered. In fact, the reading of the reports is not a pleasant thing for either ratepayers or contractors. This is the policy of the "Progressives." But they do not mean to stop at this stage. They intend to commence business as suppliers of water and gas, and, for that matter, the electric light sooner or later; as pawnbrokers, watchmakers, cobblers, bakers, butchers, and Lord Dundreary knows what. The L.C.C. harasses the electric lighting companies in the Metropolis by its pettifogging interference with underground mains and transformer-chambers, wants to swallow the City, and absorb the Board of Trade. This is the line of the "Progressives." Does it not strike you as rather hard upon supply companies that committees having no practical knowledge of the applications of electricity should be permitted to inflict their unwelcome attentions upon them? Does it not also occur to your mind that in time the L.C.C. will compete with electrical contractors in the carrying out of installation work, or that it will establish its own works and become a full-blown contractor for installations in its own—or rather the ratepayers'—buildings, which are sure to become very numerous at no distant date? If you have followed this argument—remembering that it is the "Progressives" who propose to impede your progress or take your business from you—you will know which man to vote for to-morrow. Vote for the man who will not allow, if he can help it, the Council to become a universal provider, but will respect the rights of manufacturing and contracting firms. Vote early, and never mind politics.

COMBINED ELECTRIC LIGHT AND WATER WORKS.

A rather interesting departure, which deserves special consideration now that local government has been divided and sub divided by the establishment of district and parish councils, with in many cases control over limited areas with small population, has been made at St. Lazarus, near Posen, Germany. The town has some 3,000 inhabitants, and the novelty consists in the combination of electric and water works with excellent results. Having discovered by means of boring operations that there was plenty of water in the subsoil, the local authority thought fit to ask for tenders for combined works of the nature indicated, the result being that the Helios Company, of Cologne-Ehrenfeld, were entrusted with the contract. The installation, as described recently by Mr. Luhn, of Berlin, to the Electrotechnical Society of Cologne, comprises four sections—the boiler-house, engine-room, pumping shaft, and accumulator-room. The boiler-house contains two Cornish boilers fitted with Galloway tubes and working at 90lb. pressure. One boiler is sufficient for the operation of the electrical and pumping plant, the other being kept as reserve. Space is available for the accommodation of a third boiler which is to be put down this spring. A heater is provided for heating the feed water, which is supplied to the boilers by a Worthington pump. Near the

Digitized by Google

boiler-house is situated the engine-room, in the corner of which is the pumping shaft, 20ft. deep and 17ft. in diameter. Two pumps are arranged at the bottom of this shaft. One is a compound steam-pump, whilst the other pump is driven by an electric motor by means of toothed gearing. The engine-room contains a 50-h.p. steam-engine, running at 190 revolutions, and driving a dynamo by belt. Two air-compressors operated by electricity are arranged on each side of the pumping shaft, the object of these being to increase the pressure of the air contained in two reservoirs. The accumulator-room contains a battery of 136 cells capable of supplying 200 16-c.p. lamps for seven hours. A feeder is carried from the generating station to the distributing centre, where the mains are laid on the three-wire system for private consumers, whilst a separate circuit is provided for the street arc lamps. All the conductors are carried overhead on porcelain insulators fixed to wooden posts 26ft. high. The operation of the station is as follows: During the day, when the consumption of water is comparatively great, the battery is charged, and the demand for water is met by the steam-pump. When the charging of the battery has been accomplished, and in case in the morning before firing up a greater demand for water should arise, the work is carried on by the electric pump with the assistance of the battery. At twilight the current is supplied by the dynamo, and at 11 p.m., according as the street arc lamps are switched off, the machinery is shut down and the battery takes over the supply. In the case of a fire breaking out in the town the electric pump and one of the compressors are brought into use, this being regarded as of great importance. The automatic arrangements adopted throughout the works have reduced the number of attendants, only one engineer and one boiler attendant being required. The disposition of the station has rendered it possible to supply electrical energy at the rate of 3¾ per unit. Another installation on the same plan has been carried out at the neighbouring town of Wilda.

ELECTRICITY AS APPLIED TO MINING.*

BY G. S. CORLETT, MEMBER OF COUNCIL.

Electricity has been extensively used in mining operations, and the cases in which it is so applied are rapidly increasing, so much so that it seems beyond all doubt that in the near future electric mining work will form one of the important branches of our business. I therefore feel no apology is necessary for bringing this subject before the notice of the members of this society. It is, of course, impossible for me to deal at all fully with the different branches of the subject in the time at my disposal this evening, but I wish to look briefly at what has been done up to the present and then consider somewhat in detail certain points that seem to me important. Electricity has been used in mines for (1) signalling, (2) telephones, (3) blasting, (4) lighting, (5) transmission of power.

Signalling.

So far as I have been able to ascertain, electric signals were introduced into some Yorkshire collieries about 20 years ago, and have since been extensively adopted. It would be very interesting to trace the various steps by which this system of communication has gradually been worked up to its present state—how the bichromate battery gave way to the Leclanché, the staples carrying the wires were replaced by insulators and the mechanically good bells of to-day, mounted usually in cast-iron cases, were evolved from the flimsy contrivances called by courtesy "electric bells." The arrangement of the apparatus is now so well known that a very brief description of the simplest form of signalling—viz., engine plane signalling—will suffice. In the engine-house is fixed a powerful bell with a 6in. or 8in. gong, a battery of Leclanché cells, and a plug switch. Along the roadways two galvanised iron wires are tightly strained on small bobbin insulators, and very securely bound on these insulators in the usual manner. At the distant end is placed a strong ringing key. Signals can be given by means of this key or by pressing the wires together at any point on the roadway. The size of iron wire varies from No. 8 to No. 11. The size of the bells, whether of the single-stroke or trembler pattern, is usually determined by the colliery manager. A plug switch is necessary, so that at night and other times when the signal may not be required the battery may be disconnected and leakage prevented. In most cases underground moisture is to be found at some parts of the roadway. The leakage circuits so caused are a constant strain on the battery, and consequently tend to break it down. Any number of bells can be fixed at various points to ring in any desired manner.

The present Coal Mines Act provides that signals must be arranged to ring in both directions—that is, a bell at each end. The advantage of electric signalling for mines is the speed at which signals can be transmitted over any distance. For example, in some of the Durham collieries, where the roadways extend for four miles from the shaft, signalling by the old "rapper" method often involved three or four men stationed at different parts of the roadways to transmit the signals forward. With the electric method, of course it is just as easy to signal four miles as 100 yards. This speed in signalling also tends very largely to safety in working. In case of accident, the haulage rope carrying loaded trucks can be stopped by pressing the wires at any point along the roadway, and in my own experience this has been directly responsible for saving several workmen's lives. There is the further advantage that the attendant at each station knows by the signal where the train is starting from or proceeding to, as the case may be. This system of underground communication has now been extensively adopted by collieries all over the country, perhaps more particularly in South Wales, and so little difficulty occurs in the installation and maintenance of this apparatus that most collieries manage this work without any outside electrical assistance.

Telephony.

Telephones have also been used very largely for surface work for communicating with the various departments, but only to a limited extent below ground. So many collieries have electric signal wires running into the workings; and as it is such a simple and inexpensive matter to attach telephones to the signal wires, it is surprising that more use has not been made of these instruments for underground work. Pocket telephones—that is, a small case containing a receiver and a short length of flexible wire for attachment to the iron wires—are also most useful, but comparatively few collieries have them. Where telephones have been adopted the saving of time has been enormous, and the convenience very much greater than was expected.

Blasting.

Following the strong recommendation, almost amounting to an instruction, of her Majesty's Inspector of Mines, most collieries have now adopted the electrical method of shot-firing. Shot-firing in mines has been the cause of numerous accidents occasioning in too many instances wholesale destruction of life, so that the subject deserves some consideration at our hands. I do not wish to say that the sad accidents which have occurred were due even indirectly to electricity. There has been even in this small branch of electrical work a battle between high and low tension. High tension was adopted first, but is now being gradually replaced by low-tension apparatus. Many important advantages are possessed by the latter, and I think in the near future high-tension exploders will be very little used. Exploders are small magneto machines with a simple shuttle armature which is wound with fine wire for high tension and comparatively coarse for low tension. One end of the armature coil is connected to the frame and the other led through the spindle and an insulated ebonite bush to a contact. In the high-tension exploders this ebonite bush is one of the most frequent causes of failure. Dampness is usually unavoidable, and as this ebonite bush is necessarily small, breakdowns are frequent. I have had several hundreds sent to me for repairs with this fault alone. This is a difficulty which should be easily overcome. At the same time it does not occur in low tension.

Detonators are now being manufactured of a fairly uniform quality, but until recently enormous variations occurred. For example, one lot I tested about 10 years ago required current to fire them at from 2 to 80 volts, and within the last two years I have found a number of so called high-tension detonators requiring from 300 to 400 volts, although 30 to 40 volts may safely be taken as the average pressure required. High-tension detonators are fired by means of a spark passing across the ends of the two wires inside the copper cap of ¼in. diameter. Low-tension are similar in appearance, but the ends of the above wires referred to are joined by a thin piece of platinum wire, which is heated by the current. From a manufacturing point of view I think the low-tension detonators are simpler, and, so far as my own tests go, are of a much more uniform quality. It seems to me extremely difficult to ensure that the distance between the wires in a high-tension detonator should be always uniform, but the most important advantage possessed by low-tension apparatus is that each detonator can be easily tested before use; I know of no test which can be applied to high-tension detonators, and as mis-shots are very costly in themselves and also a source of danger, this advantage cannot be too strongly insisted upon. This class of apparatus is generally used for firing some of the various high explosives, which need not be described further than the remark that their name usually ends in "ite."

* Paper read before the Northern Society of Electrical Engineers.

Lighting.

One of the earliest attempts at colliery lighting was at the Earnock Colliery in Glasgow, about 14 years ago, and I believe the plant worked very successfully for some time. The first colliery lighting job that I have any personal knowledge of was at one of the Durham pits. This was completed in or about the year 1882, and worked for a number of years. The dynamo was of the old B Gramme type with a wooden hub, series-wound field magnets, and coupled in parallel, supplying current for about 50 Swan lamps of the type then called 20 c.p. The wiring was hardly done in modern style. It is true that the wires were run in casing—the casing had only one groove, which was big enough for all wires. Fuses were entirely absent, the lampholders were of the original Swan spiral spring type, and I think switches were considered altogether unnecessary; the engine stop valve had also to do duty for the main switch. A Paterson and Cooper permanent magnet voltmeter with a loose keeper was also fixed.

It is unnecessary to describe in detail a colliery lighting plant; were I to attempt to do so my most grave and learned audience might think I had written them down as first year's students, but one or two special points are perhaps worthy of more than a passing remark. Most collieries have a fan engine with a large surplus of power, and it is often suggested that this could be used for dynamo driving, but I think that there are very few cases in which it is advisable to do this. The average speed of a fan engine may be taken at 50, and of a dynamo at 1,000 revolutions, or a 20 to 1 ratio. This involves a counter-shaft and fast and loose pulley, or a friction clutch. This gearing, with the additional belting required, often costs almost as much as a small engine, and is not so satisfactory. Five to 10 per cent. variation in the speed of a fan is not uncommon, but this variation is far too great for electric lighting work. Again, there is the uncomfortable feeling of depending on one engine for light and ventilation. I therefore think that the best arrangement is to drive the dynamo with a separate engine. Usually there is space in the fan engine-house to receive an engine and dynamo, and a more suitable place could hardly be found. The man is constantly in attendance, and is, as a rule, not overworked, and can therefore do all that is necessary for the electric light plant. The steam consumption of a colliery electric light engine need not, as a rule, be considered, and an ordinary belt-driven engine seems to answer the purpose. I have found small vertical engines running at from 200 to 250 revolutions a very satisfactory type.

The dynamo should be compound wound for 100 or 110 volts, and should always have a fair margin for extensions, as these are very likely to arise. In plants for surface lighting only, the dynamo usually runs from dusk to daylight, and from 6 p.m. to 6 a.m. is very lightly loaded. During these hours the steam consumption per unit generated is probably enormous from a central-station man's point of view, but at night there is plenty of steam to spare at a colliery, and I do not think, unless in some special cases, it would pay to lay down a small set of plant for the light load. As the electric lighting plant at a colliery has to stand a considerable amount of rough usage, it follows that the wiring should be particularly well done and the highest quality of material and workmanship employed. The advantage of distributing the lighting from certain points at which the switches and fuses are grouped, is perhaps more apparent in this class of work than in any other. Alterations to certain sections of the plant, such as screening arrangements, are constantly being carried out and branch circuits have to be removed and refixed, and not infrequently the wires of the adjacent circuits are damaged by these alterations.

In almost all the places the lamps should be enclosed in very strong fittings, absolutely dust-proof, and with a thick outer glass, which in some instances must be protected by a stout wire guard. In this district the screening and cleaning arrangements are undoubtedly the most important part of a colliery from an electric lighting point of view. A liberal amount of light should always be provided, so that when the glasses become a little dusty, as is just possible, there may still be sufficient light to detect the impurities of the coal. No general rule as to the amount of light to be provided can be laid down, as the screening arrangements vary so largely and also the quality of coal that has to be dealt with. In South Wales, for instance, very little coal screening or picking is required, while in Leicestershire house coal collieries, the small wagons from the mine are drawn into a special shed for the purpose and the best pieces are carefully selected and packed by hand in the railway wagons adjoining. Between these two extremes there is almost every possible variation, so that each individual case has to be dealt with on its own merits.

In addition to the surface lighting arrangements of collieries, electricity has also been extensively used underground for lighting the main roads, engine-houses, etc., close to the bottom of the shaft. The same remarks as to fittings, etc., apply with equal, if not greater, force underground. Where the shafts are comparatively shallow and the number of lamps is small, the underground lighting can easily be effected by a cable from the surface installation led down the shaft, but where, as in this district, 600 yards is quite an ordinary depth for a colliery shaft, and 100 16-c.p. lamps or the equivalent have to be provided, the cost of such a cable becomes a very heavy item. The conditions of underground lighting may be briefly summarised thus: The whole of the lighting is required during the day, but at night only a few lamps at each pit bottom or mouthing are used. During repairs, certain sections of the underground lighting may also be wanted during the night. These conditions imply that the best arrangement is to have a cable connected with the surface installation sufficiently large to supply the whole of the lighting with only a small loss, say four volts, and to use lamps of the same voltage as on the surface. To take a case which may be considered an average one, for a shaft 600 yards deep, 25 amperes will be required at the bottom with three volts loss; the cable will be $^{37}/_{13}$ size, and allowing 1,300 yards of 2,000 megohms vulcanised rubber will cost £342.

Volts lost.	Cable.	£
3	$^{37}/_{13}$	342
4	$^{19}/_{11}$	310
10	$^{19}/_{15}$	119

If four volts, the figures will be $^{19}/_{11}$ and £310. In addition to these figures, there will, of course, be the cost of specially strong casing, and the fixing thereof, as well as the lamps and wiring underground. Taking the cost of the latter at 30s. per lamp, it will be seen that the total capital outlay required for 50 lamps will be £425. This is a fairly large sum, and owing to the present state of the coal trade colliery managers are not inclined to lay it out in such work. It is, of course, possible to provide for a larger loss, say, of 10 volts in the shaft cable, and use, say, 110-volt lamps on the surface and 100-volt lamps underground; the cable would then be $^{19}/_{15}$ and cost £119. Assuming that the cables are provided for a 10-volt loss at full load, and that the lamps required all night are only 20 per cent. of the full load, it follows, of course, that when these lamps are burning the volts at the pit bottom will be 108, but as this pressure would very soon destroy the lamps it is necessary to either switch in a resistance or to wire them in duplicate—one set for 110 and the other for 100 volts. There is the further inconvenience that the other lights cannot be used at all unless almost the whole lot are switched on.

There are two other alternatives open: first, to lay down a separate engine and dynamo at the pit bottom, but this is generally impracticable; second, is to fix a separate dynamo to give 220 volts and couple the lamps two in series underground. This will effect a very large saving in the cables. In the case previously referred to with the same percentage of loss, the sizes of cables would be as follows:

6 volts loss	$^{19}/_{15}$	cost £119
8 ,, ,,	$^{19}/_{16}$	,, 96
20 ,, ,,	$^{19}/_{20}$	,, 45

Usually it would also be practicable to allow the 20-volt loss, as during the night dynamo volts could be lowered by a resistance in the shunt. It seems to me that for fairly large underground installations it would pay to adopt this 220-volt arrangement, in spite of the fact that two dynamos would be running all through the night at extremely light loads—one for the surface and one for the underground. Again, it is quite an open question whether vulcanised rubber enclosed in wood casing is the most suitable form of conductor for shaft work, although speaking from my own experience I have had most excellent results from this quality of cable. There are, however, various other types of insulation and protection, such as lead covered and armoured, which certainly to a colliery engineer have the appearance of mechanical strength. They are, however, very heavy, and sometimes considerable difficulty arises through not properly securing them to the sides of the shaft. This type generally costs more money than vulcanised rubber, but in my opinion it is certainly very much open to question whether it makes a better job. Where cables of a fairly good size have to be carried along the roadways of a mine, then I think it best to adopt the armoured type. In a paper of this sort I scarcely think it fair to mention the names of the makers of different kinds of cable. Remarks on the merits or demerits of individual firms' productions would only tend to ill-feeling.

The question of providing suitable hand-lamps for miners is one that has occupied electrical engineers' attention for a long time, and although very much has been done in the way of experiment, and very many different types of lamps have been brought out, yet up to the present I know of none which I could with any confidence recommend to a colliery engineer to place in the hands of his workmen generally. For some of the officials and for certain special purposes, underground portable electric lamps fitted with accumulators can now be obtained which work fairly well if the instructions as to charging are carefully attended to, and the lamp itself is kept in a vertical position, but should there be a little carelessness on either of these points, trouble and annoyance immediately result. Another very great difficulty is that up to the present no practical apparatus has been devised which can be attached to such lamps to indicate the presence of gas.

Transmission of Power.

Mining engineers have for some time past been considering the possibilities of electricity as a means of transmitting power in their mines. A certain amount of work has been done, for the most part successful, but excepting in a few cases the plants installed have been of small size and of somewhat experimental character. I mean experimental more from a mining engineer's point of view than that the electrical machines were of an unfinished or imperfect character, or, in other words, that the colliery manager was feeling his way as far as electricity was concerned. Colliery managers, it must be remembered, are directly responsible for the lives of their employés, and not unnaturally looked with some doubt upon the new power, especially since every failure was by interested parties brought into prominence. Then the widely incorrect statements made by electrical men have done much to deter electrical work. Colliery managers have been assured that the combined efficiency of engine, dynamo, cable, and driven machinery would be 90 per cent. Such a statement is of course absurd, but its very absurdity is prejudicial to our interests, as the colliery manager naturally concludes that we know nothing of our business. Again, some electrical engineers have laid down power plant in mines of a very inferior character. They have not taken the trouble to ascertain the difficulties of working, the rough usage, the scanty attention, and the large increase of power occasionally demanded. The result has been constant breakdowns with the consequent expense and annoyance. Such cases cannot be too strongly condemned; it is the whole trade which suffers, and not the individual that does the job. On the other hand, however, much good work has been done. One of the earliest, if not the first, power plant was put in by Mr. Frank Brain, in the year 1882, at his Trafalgar Colliery, and this I understand is still at work, but has since been considerably extended.

Electricity has been applied to pumping, hauling (by fixed motors and by locomotives), coal-cutting, fandriving, and drilling. A full consideration of the problems involved in any one of these sections would be quite sufficient for a separate and elaborate paper; it is, therefore, obviously impossible for me to describe each in detail, but there are certain points common to all plants which may well be commented on. Electrical engineers who undertake this class of work are pretty well agreed that the current should be supplied at a constant pressure, and I think 500 volts a very suitable standard to adopt. This will, I think, be found in practice sufficiently high to make it commercially practicable to transmit power to the ordinary distances of a mine without an extravagant outlay in cable, yet not so high as to cause a dangerous shock, nor too high for the very small motors that are occasionally required for pumping small quantities of water. It must be remembered that one of the great advantages of electrical power transmission in mines is its flexibility. It can be as readily applied to small powers as to large, and if the volts are raised much above the limit I have suggested, practical difficulties will arise in the manufacture of motors under 2 h.p. These small motors are really required in practical work. I have one or two motors working underground driving pumps which are only taking ¾ e.h.p.

The quality and sizes of cables must be almost entirely regulated by the circumstances of the particular case. For shaft work I have found good vulcanised cables last remarkably well, while for the roadways of the mines, where heavy currents are required, cable insulated with bitumen or one of the resinous compounds protected with a heavy steel armouring, and laid directly in the ground, makes an admirable job. I think in all cases it is advisable to have insulated lead and returns, although I have myself one job where an uninsulated return is used, though with only moderately satisfactory results. The return consisted at first of a steel-wire rope, but on account of its very high resistance, presumably at the joints and splices, bare copper wires were used to increase the conductivity. In a mine it is impossible to insulate such a conductor, and, generally speaking, I think it pays to spend the additional capital required and provide an insulated return circuit. For most of the operations required in mining, a series-wound motor is the most suitable. For pumping and hauling it is an absolute necessity, as an enormous torque is required to start the load. In laying down any system of power plant it is extremely difficult to obtain from the colliery engineer reliable figures as to the power required. Speaking from a somewhat intimate connection with colliery engineers extending some 10 years back, I am inclined to think that a very large number of them never trouble to ascertain what power is being expended on certain operations. For instance, if pumping plant by ropes or compressed air is being laid down, care is taken that there is an ample margin of power, and so long as the work is being done without a breakdown the colliery engineer does not measure the exact horse-power required for dealing with this particular quantity of water. Although it is a comparatively simple matter to determine the theoretical power required, the actual power is often a very much larger amount.

In pumping work, for instance, the friction of the pump and its gearing does not vary in any fixed proportion to the total horse-power. A moment's consideration will show that the friction of the pump itself will be about the same whether the pump is worked against 50ft. or 500ft. of head. Pipe friction is also an item that requires careful consideration. In the majority of cases electrical pumping work at a colliery is for a fairly large quantity of water on a comparatively small head, and the friction in the pipes may absorb quite as much power as the raising of the water. In one instance under my own charge the pipe friction is just double the power required to raise the water. In calculating the pipe friction I have used the following rule, which has the advantage of being easily remembered, and, as far as I have been able to check it, is very correct. It is due to Prof. Merivale, of Newcastle-on-Tyne, and is—

$$\frac{G^2 L}{(3d)^5} = H;$$

where G = gallons per minute;
L = length of pipe, in yards;
d = diameter of pipe, in inches;
H = head due to friction.

In haulage work the amount to be allowed for friction is also very variable. On a wet road which is badly kept, with rails allowed to get slightly out of gauge or not free from small pieces of stone or coal, the power due to friction is enormous as compared with a dry and well-kept roadway. Again, provision has to be made for the additional loads that may be put on the plant. For instance, in an endless-rope haulage system, it often happens that the rope is for short periods much more heavily loaded than is usual. The motor must be big enough to respond to this demand; indeed, in all mining work an ample margin of power is necessary. The only haulage in a colliery in this country by an electric locomotive that I know of was installed at a Yorkshire pit. A rope was laid along the roadway and secured at each end; in front of the train was a special trolley carrying a motor driving a clip pulley. The rope passed round this pulley, and the train was, so to speak, wound along. This system is not likely to be generally adopted. Another interesting case involving the use of electric locos. is at the Greenside lead mines, Ullswater. A full description of the plant will be found in the *Transactions* of the Federated Institute. In each of these cases the current is taken from overhead conductors by a sliding contact. There are a large number of collieries using machinery of various kinds that might profitably be driven by motors, and new applications are constantly being made in this direction—such as the replacement of wire-rope pumping plant or compressed-air machinery by electric plant.

There is some difficulty in describing what has been done in coal-cutting; a considerable amount of work has been done by the Coal-Cutting Corporation, but I hear various reports as to the success of the apparatus, and as I have never been able to obtain permission to inspect the plant, I am unable to give any details of its performance. There is apparently no doubt that there is a large future for a practical coal-cutter, but I think such a machine has yet to be designed; certainly I do not know of one fulfilling all the requirements. So far I have not alluded to the risk of explosions from gas. This is one of the most important problems of all, and I think that its satisfactory solution will be found in alternating-current apparatus, probably di- or tri-phase type. So far as I know, these have not been used in England, but their simplicity and the absence of brushes and commutators seems to point them out as the ideal mining motors of the future. The difficulty about low starting torque will no doubt be speedily overcome. Certain so-called safety devices have been devised for continuous-current apparatus, the most important of which probably are the steel-clad motor of Mavor and Coulson, in which the whole motor is enclosed in a steel case; the Goolden arrangement, in which the armature is enclosed; and the Davis-Stoke's method, in which the commutator is enclosed—*i.e.*, the brushes bear on the inner periphery, and the whole enclosed by a revolving ring. The first method seems undoubtedly the best, though in all I fancy the skill of the attendants bears some proportion to the safety. It is hoped that these notes, which have been hurriedly put together, may be of some service to the members, and that some of the points briefly touched upon may be fully discussed.

Discussion.

Mr. Henry Edmunds (the chairman) said that the paper covered a very wide field. There were one or two questions he would like to ask. He would like to know why the use of electricity in mining had been limited to continuous currents, and nothing said of transformers. He thought the employment of transformers would get over most of the difficulties in regard to the loss of voltage in transmission to the bottom of the pit shaft or along the galleries. The speaker then drew attention to the short note at the end of the paper, to the effect that the risk of explosions from gas might be obviated by the use of alternating-current apparatus, probably of the triphase type. Some

Digitized by Google

three years ago he was at the Frankfort Exhibition, and saw the experiments there in connection with the "Drehstrom" apparatus, exhibited by Prof. Dobrowolsky. He (the chairman) had in London a motor on that system, in which there were no brushes, which could be started electrically at full load, and which could be reversed and run in either direction. The machine was perfectly sparkless. It was interesting to note that such a motor had been evolved so peculiarly suited for mining work, although it was very little known as yet. The incandescent lamp was, of course, the safest illuminant in mines or wherever there might be an explosive atmosphere. The only difficulties were those arising from switches and fuses and cut-outs, which might spark, and thus cause the spark to come into momentary contact with the atmosphere. Mr. Corlett had said something about a difficulty arising from the fact that the ordinary incandescent lamp gave no indication of firedamp. Up to the present no practical device had been invented, but he (the speaker) would like to know what useful purpose would be served by such a device. The ordinary Davy lamp gave warning of the presence of gas owing to its construction, but surely it was not necessary to fit every miner's lamp with a gas indicator. There were many other pieces of apparatus which indicated the condition of the atmosphere with greater or less success, and the mining engineer ought not to have any difficulty in learning the state of the mine.

Mr. J. H. Rider observed that in his remarks the president had mentioned that in alternating currents was possibly found the solution of many of the difficulties met with in pit work. He quite agreed with this, and intended to have spoken on the same matter himself. Mr. Corlett had referred to vulcanised rubber cables as being suitable for use in pit shafts. He (the speaker) remembered a case, six or seven years ago, with similar cables in a Yorkshire pit, where the cable was eaten right through in a fortnight with what was found to be some saline solution coming out of the sides of the shaft. A lead-covered cable was afterwards used. He enquired whether Mr. Corlett had had any similar experience.

Mr. Fawcus said that in giving the figures of the cost of various sized cables the author had evidently never contemplated the possibility of using lamps of a voltage of from 200 to 250, or he could have halved these costs. Lamps of these high voltages could now be procured commercially; they had been used for some time successfully on the Continent where the candle-power was not less than 16 in the case of the 200 volt-lamps, and 25 in the case of the 250-volt lamps. The speaker also agreed with the remarks of Mr Rider that there was no reason why alternating currents should not be used, at all events for the lighting of coal-mines. There was also the alternative of using a pressure of 300 or 400 volts and running the lamps in series, a system adopted with success in many cases overground.

Mr. C. H. Wordingham expressed surprise that so little reference was made in the paper to sparking, which was one of the most important obstacles to the introduction of electricity into mines. He suggested that danger might arise from the bare wires used for signalling by sparking when contact was made, and also by accidental contacts causing unintended signals to be sent. He enquired whether a non-sparking cable brought out some two or three years ago, had been practically employed. The main cable was stranded over an insulated thin wire coiled within it, the two being connected together at both ends, and fuses proportionate to their sizes being inserted at the surface end. If the main cable broke, the thin wire uncoiled and remained intact, carrying the current until the fuse went at the surface, rupturing the circuit where the spark could do no harm. As regarded the author's suggestion of using a 100-volt and a 220-volt machine, he enquired why the surface lamps could not be put two in series as well as those below. The whole of Whitehaven was lighted in that way with most satisfactory results. Another way he might suggest of overcoming the difficulty of the 100-volt drop would be to put a few cells in series with the lamps at light loads to give a back pressure; these could be usefully employed when charged for bell or detonating work. He asked why the cables were not run down the shaft in an iron pipe, instead of in wooden casing. This would be much more suitable, and would prevent their being damaged by saline matter in the way referred to by a previous speaker.

Dr. Keith, having made some remarks upon electricity as used in mines in the United States, asked the author if in the formula shown the H due to pipe friction was in yards or feet He said that pipe friction was very much increased when there were many turns, bends, or elbows, which proved a very serious matter, adding very much to the head. He would like to know if Mr. Corlett had any formula for calculating that. With reference to small motors in mines, from his own experience he had known of motors running which were under 2 h.p, and even as low as ½ h.p. or ¼ h.p.

Mr. Geo. J. Somerville gave some particulars about the Earnock Colliery mentioned in the paper. Along with Mr. A R. Bennett, he was engaged at that installation in 1881. The colliery was situated about two miles from Hamilton, in the county of Lanarkshire. The dynamo was of the Gramme type and was fixed above ground. It was not driven by a special engine. The leads were taken down the shaft, which was 720ft. deep. The light was supplied by the old style of Swan lamp, and switches were fitted for each set of lights. Double-pole mercury switches, specially designed to avoid danger from sparking, were used underground. Portable miners' lamps were also used at the headings, which were about 440 yards from the foot of the shaft.

Mr. Ed. W. Cowan said that he would like to suggest another way of engineering the lighting of the roadway at the bottom of a deep pit shaft in conjunction with the surface lighting. Some speakers had suggested that an alternating current might be used, and he was about to briefly describe a way of applying an alternating current to that purpose. The alternating current might be obtained from an ordinary continuous-current dynamo, such as would be used for the surface lighting, by simply fixing two narrow collecting rings on the commutator and making electrical connection between them and opposite bars of the commutator. One pair of brushes would then supply continuous current for the surface lighting and a second pair supply alternating current to the pit shaft. At the top of the shaft a transformer would be fixed transforming the 70 volts of the alternating current up to, say, 1,000 volts. He would carry the supply to the pit bottom by means of a $^{7}/_{20}$ lead-covered concentric cable, cleated to the woodwork in the shaft. At the bottom the current would be transformed down again to the pressure required for the lamps. If they compared the cost of this arrangement with that proposed in the paper, they would find that there would be a great saving. He made it out to be £147 against £350 for the same "drop" of 4 per cent. and the same output. It was true that there was some loss of efficiency due to the iron loss in the transformers. In the case taken it would amount to 198 watts, say, three 60-watt lamps, but this was not a serious matter where coal was so cheap. There were two objections which might be raised—one was the fluctuation in the light due to the low frequency necessarily resulting from using a two pole machine as generator, but a frequency of 20 or 25 would certainly cause no inconvenience whatever in a mine. The other objection he referred to was the danger to workmen on account of the high pressure, but he thought that by using a concentric cable and earthing the "outer" there need be no fear on that account. As a further precaution, the end of the primary composing the layers wound round next to the secondary coils should be connected to the earthed outer. The "inner" would then be practically sealed from end to end. He would be glad to know if Mr. Corlett could see any practical objection to that plan.

Mr. C. M. Dorman suggested that as it was still in most instances desirable to use direct rather than alternating currents for both lighting and power transmission in mines, the financial difficulties attending the use of the abnormally long mains therein used could very often be met by the use of motor transformers. He had never yet seen a multiphase-current motor that would respond to the enormous starting torque demanded by underground engineers. He insisted, however, that the important question of the safety of the use of electric currents in fiery mines had been too cursorily dismissed in the paper. The difficulties attending the sparking which always accompanied the opening of a circuit had caused considerable anxiety to those responsible for its safe performance. Firedamp must be absolutely excluded from the box in which the switch was enclosed, otherwise when it became filled with an explosive mixture the arcing of the switch would cause the lid to be blown off, with perhaps disastrous consequences. The actual presence of firedamp in the proximity of the switching apparatus was not the only factor to be feared. The possibility existed that the periodicity of the oscillatory disruptive discharge might be so rapid that the waves radiating from the spark would travel along the ways of the mine until they found therein some metallic arrangement by which they could produce Hertzian sparks. A very small spark would ignite an explosive mixture. Although he was not prepared to specify the exact necessary conditions, it was at any rate within the realms of uncertainty that short waves started perhaps in the switchroom of a central station might travel along inside the iron pipes containing the mains until they met with the necessary syntonic conditions in, say. a manhole, and there cause one of those mysterious explosions lately so prevalent in the streets. It was a well-known fact that not only had the lampholders in the lecture theatre of the University College at Liverpool been short-circuited by waves radiating from a generator emitting electromagnetic waves of very high frequency, and consequently of very short wave lengths, but that arcs had been struck between the carbons of an arc lamp when they were suitably polarised, but not quite in actual contact. Was there one of them prepared to assert that under favourable conditions the opening of a switch in a circuit fed by an alternating source of ordinary frequency, or even by a direct current, might not set up waves radiating from its oscillating arc of such high frequency as to be capable of exciting any syntonic resonator in the vicinity? Mr. Dorman, in a communication to the society, added that it seemed he had not made it quite clear to which waves he had referred. The wave length was of course equal to the ratio of the speed of propagation to the frequency; consequently the waves thrown out from an alternator whose periodicity was 100, would be $186{,}660 \div 100 = 1{,}866$ miles long. But the electric and magnetic waves do not travel together in phase until a distance from the origin of a quarter of a wave-length is reached. Hence the nearest distance from the source at which such action could take place would be $1{,}866 \div 4 = 466$ miles, or as far as Inverness from London. Certain parts of the installation might, however, happen to be so arranged as to capacity and self-induction as to cause an oscillatory spark having a periodicity of perhaps a thousand million per second, and consequently emit radiation of only a foot wave length. It was to these shorter waves that he had referred in his remarks.

Mr. Bally, in reference to the short-circuit that had been produced in the lecture theatre at University College, Liverpool, said that it had been caused by the electromagnetic waves emitted by an exceptionally large oscillator of Hertz pattern acting on a large rectangular circuit of some 70ft. circumference, which was formed by the electric light leads and some stay wires. The striking effects produced by these very rapid disturbances of short wave length would be reproduced only in an exceedingly small degree by the comparatively slow disturbances of enormous wave length

Digitized by Google

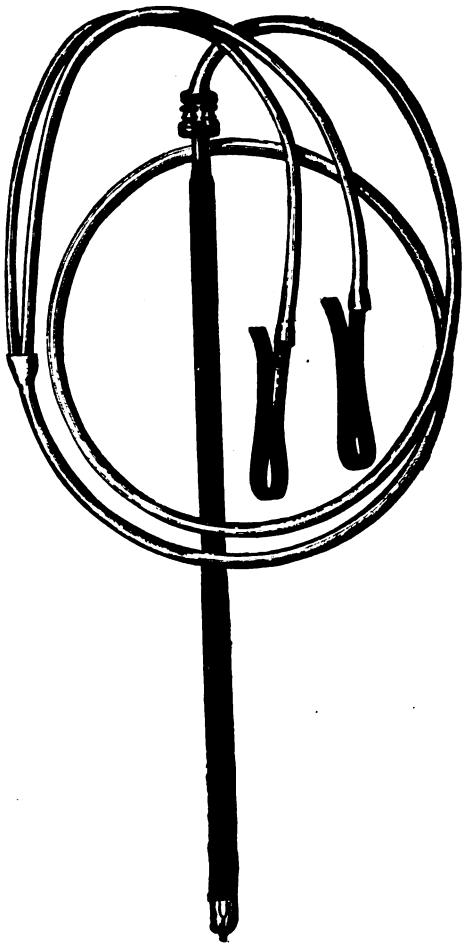
given out by the ordinary alternating current, and hence there was no fear of a similar catastrophe occurring and producing sparks in a coal-mine. He wondered that the dangers of sparks in mines had not been dealt with more fully. An electric spark discharge was one of the favourite ways of exploding mixtures of gases in the laboratory, and one of the points to which most attention was paid by manufacturers of electric mining plant was the elimination of sparking or the careful shielding of the spark, if its production was unavoidable. He thought that the charge against English engineers of slowness in adopting polyphase-current motors was hardly justifiable. Although the efficiency of those motors was fairly good, and some of them would start with a moderate load, no one would claim that they could start with some two or three times the normal load, which was an essential requirement for haulage and traction, and which any good continuous-current series motor could easily manage.

Mr. Corlett, in reply, said he began to read his paper with a lively feeling of failure. Owing to the very short time available for preparing it, it was, of course, impossible to take in detail one particular branch of the subject, and it was therefore considered best to attempt a general sketch of what had been done up to the present in this country. There were important mining installations in Europe and America, and at some future date a description of some of them would be instructive and interesting. The president and others had suggested for underground lighting the use of alternating-current appliances. In one colliery the speaker's firm had put down such a plant, working at 2,000 volts, not so much for the sake of reaching underground workings, but for lighting the owner's residence 1½ miles away. It must be remembered, in the first instance, that at a colliery there were at present no skilled electrical engineers The electric light plant had to be worked by an ordinary engineer of the colliery, and in many cases he was far too busy to devote any personal attention to it. The plant was put down somewhere, and it had to run. In the plant referred to, elaborate measuring instruments were not purchased, and occasional failures occurred on the high-pressure wires. For very large plants, which would warrant a thoroughly high-class man being engaged, no doubt such apparatus would give perfect satisfaction, but for small lighting installations at a colliery trouble and annoyance would probably result. An ordinary plant did not involve more than about 300 lamps of 16 c.p. for any one colliery, and very often only required 60 to 150 lights. One did not see much of alternators of that size at 1,000 volts. Most alternating tests started at 25 kilowatts, and increased up from that, but as a rule they did not come down below it. In reply to Mr. Cowan's suggestion, it was rather surprising to hear how cheaply the cost came out, and that seemed a very easy way of doing it. It was often impracticable to run, say, a 220-volt circuit on the surface to include general offices, cabins, etc., where one light was often required. Then all that work had to go more or less under the control of H.M. inspectors of mines, whose general feeling was apparently against the introduction into mines of high pressures. It was quite true that in his paper the question of sparking had not been dealt with. That was partly because the great proportion of electric transmission work in mines at present had been placed on the main intake—that was to say, on the main road over which fresh air from the surface was passing to all the workings. As the ventilation of mines had lately been generally improved, so that there was a strong current of fresh air all along those roadways, any gas that might possibly be given off was immediately cleared away. It was at the workings themselves as the coal was being moved that bodies of gas were likely to be given off. That was also the reason why the gas-indicating apparatus must be attached to the lamp itself. The roadways were narrow—in some mines 3ft. was a wide and high roadway—and 2ft. was not an exceptional one, the man having to crawl along with the lamp perhaps in his mouth, and might come into a volume of gas and be suffocated before he would have time to get out, unless his lamp indicated the presence of the gas. Gas indicators must be attached to the large proportion of lamps in collieries. In some cases, where a large number of men was working close together under one official, a lamp without a gas indicator might be used by the men themselves. Mr. Fawcus had asked why 200-volt lamps should not be used. He (the author) did not know where to get them of good quality. He had tried (not very recently) lamps up to 130 and 140 volts, which burnt any time from three minutes upwards. If there were lamps of 200 volts, of 16 c.p. or 32 c.p., which had a life of, say, 1,000 hours, and an efficiency of three to four watts, they could be used about collieries very largely, and effect a very considerable saving. Mr. Dorman had mentioned the fact that static charges might be given by alternating current, and had also made some remarks about Hertzian waves, from which it would appear that there would not be much chance of doing any more mining work; but it was comforting to hear from Prof. Baily that collieries were too small for a wave to take any notice of. At the same time, the subject was very interesting, and it was to be hoped that at an early date more information would be laid before the society. Mr. Clirehugh had criticised the suggested standard of 500 volts, considering the severe shock a drawback, but in spite of that the author thought a pressure of 500 volts was useful for every class of mining machinery except, perhaps, coal-cutting, for which possibly 250-300 might be preferable. Mr. Clirehugh had also stated that English engineers had very little idea of what was being done, and instanced a particular installation as a very good job, and was very careful to state that it was done by a foreign firm. It was, however, possible that no English manufacturer had a chance of quoting for the necessary plant. Mr. Wordingham had spoken about a safety cable on rather an extensive job in the county of Durham. Two or three miles of that cable were laid down, but the author had no definite information about its performance. In reply to Mr. Wordingham's suggestion to use iron pipes for the shaft cable, he did not think it would be wise, as it was difficult to get at the cable, and, in addition, its whole weight would be on one support at the top, and with a 600-yard shaft that arrangement would be impracticable. In answer to Dr. Keith, the author stated that the formula gave the head in feet. In conclusion, the author expressed the hope that some other member would take up one section of mining work and read a paper on the subject.

The Chairman said he hoped members would consider Mr. Corlett's suggestion that detailed papers might be read on some of the topics touched upon that night. He asked the meeting to accord a very hearty vote of thanks to Mr. Corlett for his admirable paper.

BATTERY INSPECTION LAMP.

A very useful lamp for utilisation in central stations and private installations where accumulators are put down, has been introduced by the Electrical Power Storage Company, Limited, of 4, Great Winchester-street, E.C. The lamp—the construction of which is represented in the accompanying illustration—is provided with a length of flexible cable, so as to be readily carried from cell to cell for putting into the electrolyte between



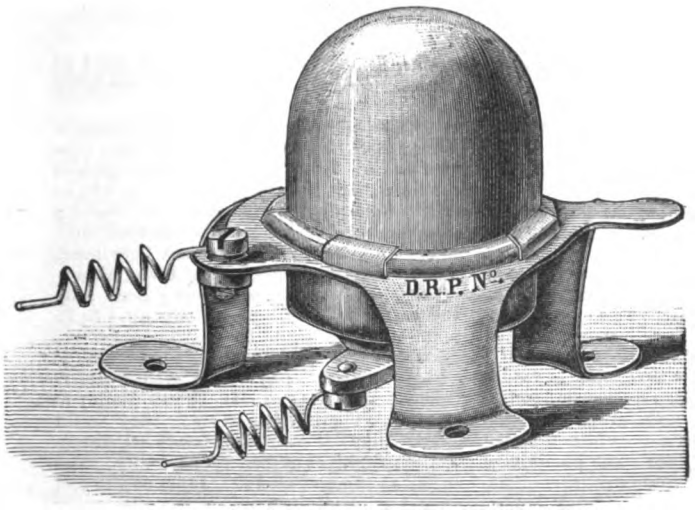
the plates of the E.P.S. batteries. It will be readily understood that a lamp of this kind will be found especially useful for inspecting in lead or lead-lined boxes the condition of the plates, which cannot otherwise be easily seen. Besides the flexible connections, the lamp is fitted with springs to grip on to the lead connecting bars of adjacent cells—a four-volt lamp being used. The lamp has already been adopted in central-station work, where it has proved of great utility.

TEMPERATURE ALARM.

In the annexed illustration is shown a new temperature alarm, which has been brought out by Messrs. Naglo Bros., of Berlin. It is claimed that this alarm fulfils all the requirements necessary in such an instrument. Its advantages are simplicity, punctuality, and cheapness. The alarm consists of a compartment which is divided into two unequal parts by means of a flexible division. These are filled with two gases of different expansion, and if the temperature rises the circuit is closed and an alarm is given. This apparatus, which can be adjusted to any desired degree, is exceedingly sensitive, and

Digitized by Google

absolutely independent of external air pressure. Its sensitiveness is shown by the fact that it is only necessary to touch the compartment with the palm of the hand or to breathe on it in order to set the bell in motion. It is claimed that by the use of this alarm, which is being introduced in this country by Messrs. J. Bartels and Co., of 25, City-buildings, 23, Old Hall-street, Liverpool, that a fire should have no chance of extension, being announced at its commencement. This apparatus



should highly recommend itself for steamers or sailing vessels with inflammable cargo, and it is also used to advantage on the Continent in factories for raising an alarm in case of the heating of machinery, etc.

ELECTRIC LIGHTING AND TRAMWAY PROVISIONAL ORDERS.

The following is a list, together with the proposed capital expenditure, of the applications for electric lighting provisional orders to be considered during the present session :

Alderley Edge.—To authorise the Alderley Edge Urban District Council to supply electricity within the district. £10,000.

Bath.—To authorise the City of Bath Electricity and Engineering Company, Limited, to supply electricity within the city of Bath. £38,774 already expended.

Battersea.—To authorise the County of London and Brush Provincial Electric Lighting Company, Limited, to supply electricity within the parish of St. Mary, Battersea. £20,000.

Bootle.—To authorise the mayor, aldermen, and burgesses of the borough of Bootle to supply electricity within that borough. £20,000.

Bray (Ireland) Township Improvement Bill.—To authorise the Bray Township Commissioners to supply electric light for public and private purposes.

Brechin.—To authorise the Scottish House-to-House Electricity Company, Limited, to supply electricity within the Royal burgh of Brechin. £20,000.

Carlisle.—To authorise the mayor, aldermen, and citizens of the city of Carlisle to supply electricity within that city. £40,000.

Leigh.—To authorise the Leigh Local Board to supply electricity within the urban sanitary district of Leigh £25 000.

Liverpool.—To authorise the Liverpool Electric Supply Company, Limited, to supply electricity within portions of the city of Liverpool, and of the Local Government district of Toxteth Park. £20,000.

Llandudno.—To authorise the Urban District Council of Llandudno to supply electricity within the urban sanitary district of Llandudno. £14,625.

Luton.—To authorise the mayor, aldermen, and burgesses of the borough of Luton to supply electricity within that borough. £10,000.

Margate.—To authorise the Municipal Electric Light and Power Corporation, Limited, to supply electricity within the municipal borough of Margate. £15,000.

Montrose.—To authorise the Scottish House-to-House Electricity Company, Limited, to supply electricity within the Royal burgh of Montrose. £20,000.

Motherwell.—To authorise the Commissioners of the burgh of Motherwell to supply electricity within that burgh. £12,500.

Newington.—To authorise the County of London and Brush Provincial Electric Lighting Company, Limited, to supply electricity within the parish of St. Mary, Newington. £20,000.

New Windsor.—To authorise the mayor, aldermen, and burgesses of the borough of New Windsor to supply electricity within that borough and the Eton urban district. £18,500.

Notting Hill.—To authorise the Notting Hill Electric Lighting Company, Limited, to supply electricity within a portion of the parish of St. Mary Abbotts, Kensington.

Pontypool.—To authorise the Pontypool Electric Light and Power Company, Limited, to supply electricity within the district of the Pontypool Local Government Board. £6,689.

Prescot, Huyton and Roby, Rainhill, Eccleston and Whiston.—To authorise the British Insulated Wire Company, Limited, to supply electricity within the districts of the Prescot and Huyton and Roby Local Boards ; and the townships of Rainhill, Whiston, and Eccleston. £15,000.

Radcliffe.—To authorise the Radcliffe Urban District Council to supply electricity within the urban sanitary district of Radcliffe. £20,000.

St. Olave's.—To authorise the County of London and Brush Provincial Electric Lighting Company, Limited, to supply electricity within the district of the St. Olave's District Board of Works. £20,000.

Salisbury.—To authorise the Salisbury Electric Light and Supply Company, Limited, to supply electricity within the city of Salisbury. £20,000.

Southampton.—To authorise the Southampton Electric Light and Power Company, Limited, to supply electricity within the county borough of Southampton.

Stirling.—To authorise the Commissioners of the burgh of Stirling to supply electricity within that burgh. £12,000.

Strand District.—To authorise the Charing Cross and Strand Electricity Supply Corporation, Limited, to supply electricity within the district of the Strand District Board of Works. £30,000.

Swindon New Town —To authorise the Swindon New Town Local Board to supply electricity within the urban sanitary district of Swindon New Town. £15,000.

Walthamstow.—To authorise the Walthamstow Local Board to supply electricity within the Local Government district of Walthamstow. £11,000.

Winchester.—To authorise the mayor, aldermen, and citizens of the city of Winchester to supply electricity within that city. £20,000.

Windermere and District.—To authorise the Windermere and District Electricity Supply Company, Limited, to supply electricity within the districts of the urban sanitary authorities for Grasmere, Ambleside, Bowness, Windermere, and Kendal ; the district of the Kendal Union Rural Sanitary Authority ; the districts of the urban sanitary authorities for Ulverston and Grange ; the district of the Ulverston Union Rural Sanitary Authority ; and a portion of the district of the Lancaster Union Rural Sanitary Authority. £50,000.

Worthing.—To authorise the mayor, aldermen, and burgesses of the borough of Worthing to supply electricity within that borough. £27,500.

Tramway Bills and Provisional Orders.

The Dublin United Bill authorises the use of electric powers, and working agreements with the Clontarf Company.

The Leeds Corporation Bill authorises additional tramways ; the use of animal, steam, or any mechanical power ; and power to Corporation to work the tramways.

The London County Bill authorises the County Council to work their tramways, and to agree with other parties as to exercise of running powers.

The London, Deptford, and Greenwich Bill authorises the construction of new tramways ; extends the time for the completion of certain tramways authorised by Acts of 1889 and 1891 ; and sale to County Council and leasing of tramways.

The London Street Bill authorises the company to accept a lease of any tramways acquired or constructed by the London County Council and other local authorities.

The South Shields Corporation Bill authorises the Corporation to construct tramways on a gauge of 3ft. 6in., to be worked by animal, steam, or mechanical power ; running powers over existing tramways ; and power to Corporation to work the tramways.

The Aldershot and Farnborough (Extension) Order authorises the construction of additional tramways in the neighbourhood and suburbs of the camp at Aldershot, and through the town of Aldershot, to be worked by animal, steam, electric, or any mechanical power.

The Carlisle and District Order authorises the construction of tramways in Carlisle and district on a gauge of 4ft. 8½in., to be worked by animal or any mechanical power not being steam power.

The City of Gloucester Order authorises the construction of tramways in Gloucester, and parishes of Upton, Saint Leonard, Hempstead, and Tuffley ; power to work such lines, and the tramways already authorised, by animal, electric, or other mechanical power ; the removal of certain existing tramways.

The Great Yarmouth Order authorises the construction of tramways in the borough on a gauge of 3ft. 6in., to be worked by animal or any mechanical power other than steam.

The Hartlepool Electric Order authorises the construction of tramways in West Hartlepool, on a gauge of 3ft. 6in., to be worked by any mechanical or electric power ; and running powers over lines authorised by Hartlepool Tramways Order, 1883.

The Hartlepools Order authorises and confirms an agreement between Mr. T. Trafford Moyes and Mr. Stephen P. W. d'Alte Sellon, for the transfer of the undertaking to Mr. Sellon ; and the amendment and extension of the Hartlepools Tramways Orders, 1883, 1884, and 1888.

The London, Deptford, and Greenwich Order authorises the construction of tramways in Tooley-street and Parker's-row, to be worked by electric or any mechanical power other than steam.

Digitized by Google

The London United Order authorises the construction of tramways in the parishes of Hammersmith and Acton, to be worked (as well as the existing tramways) by animal or by any mechanical power.

The Newcastle-upon-Tyne Corporation Order authorises the working of the existing tramways by cables and ropes, and the borrowing of £130,000.

The Somerton, Keinton-Mandeville, and Castle Cary Order authorises the construction of a deviation tramway in the county of Somerset.

The Wigan and District Order authorises the construction of extension tramways in the districts of the Hindley and Ince-in-Makerfield Local Boards and the borough of Wigan.

TRANSFORMER-CHAMBERS IN LONDON.

The following report of the Highways Committee of the London County Council, presented to the latter on Tuesday, will be read with interest by all concerned in the electric lighting of the Metropolis. It may also be as well to bear in mind that the Mr. A. Bassett Hopkins mentioned in the report is a member of the L.C.C.

Electric Lighting Acts and Orders—Appeals of the County of London and Brush Provincial Electric Lighting Company against decisions of the Council.

We reported on October 23 last that the County of London and Brush Provincial Electric Lighting Company had appealed to the Board of Trade against the Council's disapproval on second idem of the company's proposal in notices dated August 23 and 29, to construct many transformer-chambers of large size under the public streets in St. Luke's, Clerkenwell, and Wandsworth, and we then stated that we were taking the necessary measures to have properly brought before the Board of Trade the Council's objection to the wholesale appropriation of the public thoroughfares for the purposes of private enterprises. The Board of Trade held an enquiry on December 13 and 20 last with reference to the proposed systems of supply under (*a*) County of London (North) Order, 1892; (*b*) Southwark Order, 1892; (*c*) Wandsworth Order, 1892 in respect of all of which the County of London, etc., Company are the undertakers; (*d*) House-to-House Company's Order, 1889; (*e*) Hampstead Order, 1892, and Islington Order, 1892, the respective vestries being the undertakers under the two last orders

At this enquiry the County of London and Brush Provincial Company was represented by Mr. Cripps, Q.C., and the House-to-House Electric Light Supply Company, whose system of supply is similar to that of the County of London Company, was also represented by counsel (Mr. G. A. Scott), and a formidable array of witnesses appeared on their behalf, while the Vestries of Clerkenwell, Hampstead, Islington, Kensington, St. Luke, and St. George's, Southwark, and the Wandsworth District Board were also represented. The Council's case was conducted by Mr. A. Bassett Hopkins, and we are glad to take this opportunity of recording our sense of the value of the services rendered by him in the matter without fee or reward. In view of the eminence of some of the witnesses on the other side, among whom were, we may mention, Sir F. J. Bramwell, Dr. J. A. Fleming, and Dr. Silvanus Thompson, we considered it necessary to engage expert witnesses of some note on behalf of the Council. We therefore gave instructions for Sir Benjamin Baker, Dr. J. Hopkinson, and Mr. Enright, to be retained, and these gentlemen supported the evidence of the Council's engineer. The fees payable to these gentlemen for their services, and some other minor expenses in the matter, amount to about £150.

The Board of Trade has since intimated that, having considered the objections to the proposed systems of supply under the orders above specified, it is not prepared to hold that sufficient reasons have been advanced, either on the ground of public safety or of want of parliamentary sanction, to justify the Board in refusing to approve of a system of supply which involves the use of transformer-chambers under the public streets, but that the user of the streets for the purpose should be limited and the chambers so placed as not unreasonably to interfere with existing underground work; that the Board will approve the system with certain alterations; and that the Board hopes that this decision on the general question will render unnecessary any further action on the appeals lodged by the County of London and Brush Provincial Electric Lighting Company.

We have informed the companies concerned that in connection with any notices for the construction of transformer-chambers full particulars and plans must be supplied showing the exact position to be occupied by, and the internal and external dimensions of, each of the chambers proposed to be constructed, and also the existing works which will be disturbed thereby; and that the Council reserves its right to approve with or without conditions, or to approve the construction of all or any of the chambers referred to in such notices. We recommend (*a*) that the Council do disapprove of the action taken by the Highways Committee with reference to the appeal to the Board of Trade by the County of London and Brush Provincial Electric Lighting Company, and that, subject to an estimate being submitted by the Finance Committee in accordance with the statute, payment be authorised of a sum not exceeding £150 for the fees of the expert witnesses retained and some other incidental expenses in support of the Council's case; (*b*) that the cordial thanks of the Council be given to Mr. A. Bassett Hopkins for the services rendered by him in having so ably conducted the Council's case at the Board of Trade enquiry with reference to the appeal.

COMPANIES' MEETINGS AND REPORTS.

CITY OF LONDON ELECTRIC LIGHTING COMPANY, LIMITED

An ordinary general meeting of this Company was held at Winchester House on Wednesday, Sir David Salomons occupying the chair.

The **Chairman**, in moving the adoption of the report, spoke of the advantages of the electric light, which did not, like gas, condense in the pipes and give a bad light, or freeze up altogether. As in the previous year, there had been very little fog, but an impartial critic would say the Company had given a satisfactory supply, and that the organisation was also in a satisfactory condition. The gross income was now about £114,000. He had previously had to apologise to the ordinary shareholders for not being able to give them dividends, but the concern was new, having been only two years at work, and the public had still to be educated to it. They had now turned the corner, and begun to pay 5 per cent. to the ordinary shareholders, which was not a mean dividend, and he trusted that they would in the future never pay less. The chief alteration in the staff had been the appointment of Mr. Frank Bailey as engineer to the Company. Upon this appointment they could congratulate themselves, and they had already benefited therefrom The business of the Company had grown very rapidly. The number of consumers was 242 at the end of 1892, 1,080 at the end of 1893, and 2,740 at the end of last year. This increase would not go on for ever, but the progress shown was gratifying as proving that the citizens of London greatly appreciated the Company's efforts; £19,064 had been written off in order to pay for all the expenses connected with the issue of the various classes of shares and the debenture stock. The ordinary shareholders had sacrificed a good deal in having permitted the Board to issue preference shares and debenture stock at a higher rate of interest than possibly it was necessary to offer, but this had enabled them to be issued at a premium, by means of which a reserve fund had been formed. The combined reserve and depreciation fund was not idle money, but was invested in consols to the amount of £40,000 odd, and £15,200 was invested in Metropolitan 2½ per cent. consolidated stock. The present market value of these securities was £56,000, to which had to be added the balance of premiums on the last issue of debenture stock and other sums, making a total altogether of about £90,000 They had had trouble in connection with their condensing plant at Bankside, as the strainers choked very rapidly owing to the leaves and straw in the Thames. A new machine was being designed to clear the strainers. The public lighting of the City had been satisfactory, the gas-posts having been moved away shortly after their last meeting. There had been only six breakdowns, and the number of lamp-hours was over 2,000,000, and the percentage of extinction 0·067. In private lighting the percentage was 0·012. They had arranged a system of discounts so as to reach the small consumer. They were waiting for an order from the Corporation for lighting the lesser streets, and were urging them to come to some decision as to the system to be adopted for lighting the same. They had acquired at fair market value a big oil-stores next door to their works. This had been a danger to them, and they could put up offices and stores on the site. After alluding to the dinner which was given by the Company at the Cannon-street Hotel in order to demonstrate the advantages of electrical cooking, the Chairman said that the whole of their boilers, with one or two exceptions, were fitted with automatic stokers, which was an economy, and the smoke nuisance had been abated. They now had 157,000 to 160,000 lamps connected, and they had an ample reserve. They metered last year 2 602,217 units, compared with 1,741,099 units in 1893. The working expenses fell as the output became greater; but, on the other hand, as their machinery increased, the depreciation and reserve must increase. The statutory price was 8d. per unit, but the average price received by the Company was 7·7d., owing to discounts. There were now 144,086 lamps connected, and 7,157 to connect. Applications were coming in to the average number of about 1,000 per week. The staff had done their best in every way.

Mr. Joseph Braithwaite, jun., seconded the motion, and made a speech, but as the chairman had pretty thoroughly covered all the ground, his observations were mainly a repetition of those of Sir David Salomons.

Some questions were asked, among those speaking being **Mr. Sydney Morse**, who suggested that the Company should proceed against the gas company for damages in connection with the Southwark Bridge explosion.

In reply to the questions, the **Chairman** said that the Company knew nothing more about the telephone tube matter than was to be read in the reports of the meetings of the Commissioners of Sewers. As regarded explosions, the question was under the consideration of the Board of Trade. They were doing their best to avoid accidents, and did not propose to take action against the gas company, with which they were on good terms. The lesser streets in the City would be lighted as soon as they could get the Corporation to decide. The allowing of discounts would not have an injurious effect, but the contrary.

The motion having been adopted, the **Chairman** moved and **Mr. E. Lucas** seconded the payment of the dividends. The

Digitized by Google

Chairman moved and **Mr. McCrory, Q.C.**, seconded the re-election of the retiring directors, Mr. Lucas and Colonel Martindale. The **Chairman** moved and **Mr. F. W. Reynolds** seconded the issue of the remaining £100,000 of debenture stock, and **Mr. H. P. Leach** moved and **Mr. S. Marriott** seconded the re-election of Messrs. Pannell and Co. as auditors. All these motions were passed unanimously.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY, LIMITED.

The thirty-first ordinary general meeting of this Company was held on Tuesday at the offices, 38, Old Broad-street, Admiral Sir George H. Richards, K.C.B., occupying the chair.

The **Chairman**, after referring to the death of one of the directors, Mr. Philip Rawson, said that the Board had lately elected Sir Robert Herbert and Admiral Sir Anthony Hoskins as directors. The Board could congratulate the shareholders on the results of the last year's work. They had carried out two rather large operations last year. They had laid a cable for the Eastern Extension Company by the China Seas, between Singapore and Labuan in Borneo, and Hong-Kong in China. This cable was something over 1,700 miles in length. Then they had laid a cable for the Anglo-American Company across the Atlantic between Ireland and Newfoundland. That cable was somewhere about 2,000 miles in length, and he believed it was a cable of the largest capacity that had ever been laid. Both these works were carried out with great success, and they were crowded into the half-year. Since then they had laid some smaller lengths of cable for various foreign Governments and companies. and on the whole they had been able to pay a dividend of £1. 8s. a share, including the interim dividend paid in July. The Company had no contracts in hand, and they were meeting this year with really less work in progress than they had had for some time before. It not unfrequently happened that most of the year's work came at the half-year, as it did last year. They, therefore, hoped to get better business, and, at all events, they might depend that all the exertions of the Company and the executive would be devoted to that end. Their particular work at present was manufacturing certain lengths of store cable to be ready for use, and they were taking advantage of the lull to put the machinery into such a state that it would enable them to do the work more economically and efficiently when there was a demand upon it.

Mr. Campbell seconded the adoption of the report, which was unanimously agreed to.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED.

An extraordinary general meeting of this Company was held yesterday afternoon at the Cannon-street Hotel to consider and, if approved, to confirm as special resolutions certain resolutions which were passed at the extraordinary general meeting held on 5th ult., and to which we referred at the time.

In the absence of Mr. J. S. Forbes, owing to influenza, the chair was taken by the Earl of Lichfield.

The **Chairman** said it was not necessary to say much on the subject, the object of the proceedings being to obtain a quotation on the Stock Exchange.

Major Flood-Page seconded the resolution, which was carried unanimously.

NOTTING HILL ELECTRIC LIGHTING COMPANY, LIMITED.

Directors: William Crookes, Esq., F.R.S. (chairman); Arthur Ellis Franklin, Esq.; Alexander Howden, Esq.; James Thomas Jervis, Esq.; Francis Radford, Esq.; Sidney Waters, Esq. Engineer and manager, G. Schultz. Secretary, R G. Rawkins.

Report of the directors and abstract of accounts at December 31, 1894.

The expenditure on capital account at the date of the last balance-sheet amounted to £78,528. 19s. 10d. During the year a further sum of £5,032. 1s 7d. was expended, bringing up the total to £83,561. 1s. 5d. The principal item of expenditure is £4,083. 4s. 7d. for mains—the greater part of which represents the cost of the extension to Melbury-road and Addison-road. Against this capital expenditure £4,410 of preference shares were issued. The preliminary expenses, compensation, and cost of administration during construction, amounting to a sum of £5,205. 5s. 4d., have been transferred to a suspense account, with a view to their being gradually written off out of revenue by means of a sinking fund. The total expenditure charged to capital account now stands, therefore, at £78 335. 16s. 1d. The revenue account shows a profit of £2,401. 17s. 8d., as compared with profits of £1,481. 7s. 1d. in 1893, and £112. 6s. 1d. in 1892, and a loss of £554. 18s. 6d in 1891. The amount received from the sale of current shows an increase of £687. 4s., and the expenditure shows a decrease of £127. 2s. 8d The directors, who are entitled to fees amounting to £1,000, propose to draw for their services for the year 1894 the sum of £300. After payment of this sum the revenue account shows an available profit amounting to £2,101. 17s. 8d. Out of this the following sums have been set aside—(*a*) to depreciation, £600; (*b*) to 3 per cent. written off the preliminary expenses, £156. 3s. 2d., leaving a balance, after allowing for the other items on the net revenue account, of £1,243. 14s. 7d. available for dividends, which the directors propose to distribute as follows: (1) by the payment of a dividend at the rate of 6 per cent. per annum, less income tax, on the ordinary preference shares for the year ending December 31, 1894, £566. 6s. (an interim dividend on these shares was paid on July 31); (2) by the payment of a dividend at the rate of 2s. per share free of income tax on the ordinary shares, £645. 4s.; (3) carrying forward the balance of £32. 4s. 7d. The engineer reports that the machinery and plant at the central station, as well as the mains, are in good condition, and no accident of any kind has occurred. In view of recent occurrences in other districts, the directors are taking steps to ventilate the culverts in order to prevent any possible accumulation of gas. The number of houses on the circuit has increased from 173 to 234, and the number of lights from 12,153 to 15,669. The House-to-House Electric Light Supply Company, Limited, having decided to abandon their area in the northern part of Kensington, your directors, after prolonged negotiations with the local authority, decided to apply to Parliament for powers to extend over the whole of the northern portion of Kensington, thereby more than doubling the area served by them. An extraordinary general meeting was called in order to modify the articles of association so as to give the directors the necessary powers, and application has been made in the usual form through the Board of Trade to Parliament for an extension order for the district in question. The standing orders having been complied with, and no notice of opposition having been given, the directors anticipate that the necessary powers will be conferred upon them during the current session. If the extension powers are granted, the area of this Company will consist of almost the whole of that part of the parish of Kensington north of Kensington High-street. The directors desire to express their appreciation of the services of Mr. George Schultz, their engineer and manager, whose zeal and energy has largely contributed to the progress of the Company. The directors who retire are Messrs. A. E. Franklin and Francis Radford, and, being eligible, they offer themselves for re-election. The shareholders' auditors, Messrs. Fox, Sissons, and Co., retire, and, being eligible, they offer themselves for re-election.

REVENUE ACCOUNT, YEAR ENDING DEC. 31, 1894.

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC., DURING THE YEAR ENDING DEC. 31, 1894.

Quantity generated in B T. units	145,948
Quantity sold to private consumers by meter	130,266
Quantity used on works for lighting and testing	3,652
Total quantity accounted for	133,918
Quantity lost in distribution and not accounted for	12,030
Total maximum supply demanded (8-c.p. lamps)	15,669

In moving the adoption of the report on Tuesday, the **Chairman** (Mr. W. Crookes) said that the progress of the Company, though slow, was certainly sure. The issue of preference shares had increased by 441. Since the end of the year, however, a further 450 of these shares had been allotted, leaving the unissued share capital at the present time at £12,610. Borrowing powers which extended to £50,000 had not yet been exercised. The amount spent on capital account during the year amounted to £5,032. 1s. 7d., but, notwithstanding this fact, the total expenditure was £193. 3s. 9d. less than that which appeared in the previous year's account. The explanation was that the sum of £5,205. 5s. 4d. in former accounts, representing the cost of general administration and management expenses, etc., during construction and preliminary expenses to the first general allotment of shares, had been transferred, under the advice of the auditor of the Board of Trade, to a suspense account. There had been an increase in the revenue of £793. 7s. 11d, and the expenses for the same period had decreased by £127. 2s. 8d. The staff deserved thanks for the manner in which they had carried out their duties in order to bring about that result. The business was now being worked on more economical lines than any similar undertaking in London. The gross profit had risen from £1,481 to £2,401, showing an increase of nearly 70 per cent. This, of course, was brought about principally by the additional number of lamps connected; these had increased to the extent of 3,500 during the year, or more than 800 above the additions for the previous year, being, in fact, a larger increase than during any 12 months since the commencement. Nearly £1,300 had been taken out of the year's revenue for repairs and depreciation, or 25 per cent. of the gross receipts. The lamp earnings were still very low, reaching only to about 6s. for each 8-c.p. lamp, but considering the smallness of the Company's output, the sheer cost per unit reflected the greatest credit on the engineering staff. Towards the end of the year an important extension of the mains was made from the Phillimore district along Kensington-road, throughout Melbury-road, and a part of Addison-road. Powers had also been applied for to light an additional area. No accident of any kind had occurred, and although the winter had been exceptionally severe everything had progressed satisfactorily, with the exception of a little water recently getting into the culverts through the bursting of a water-pipe. No stoppage whatever had occurred in the supply of current throughout the year. With one exception of two hours, current had been supplied to their customers day and night uninterruptedly since it was first switched on in May, 1891. Now that the dividend earning point had been reached there was every reason to believe that it would go on increasing, and the future increased prosperity of the Company seemed to him fully assured.

Mr. A. Howden seconded the motion, which was adopted unanimously.

Mr. Burness moved, and **Mr. Battanshaw** seconded, the re-election of the retiring directors, which was agreed to.

On the motion of **Mr. Matterson**, seconded by **Mr. Bradford**, the auditors were reappointed.

CHELSEA ELECTRICITY SUPPLY COMPANY, LIMITED.

Directors: J. Irving Courtenay, chairman; Major-General Webber, C.B. (retired R E.), deputy-chairman; Nugent Daniell; Emile Garcke; George N. Marten. Managing engineer, Frank King. Secretary, S. J. Cluer.

Report of the directors (with abstract of accounts) to be presented to the ordinary general meeting of the Company, to be held at the Central Station, Draycott-place, S.W., on Tuesday, March 5, at 12 noon.

The 6,000 6 per cent. preference shares of £5 each issued in April last at a premium have been fully subscribed. The balance of premiums on the preference shares, after deducting the expenses of issue, amounts to £1,399. 18s. 7d. This sum has been applied to the reduction of the preliminary expenses account in the general balance-sheet, and a further sum of £834. 4s. 5d. has been taken from profits to extinguish this account. The revenue account shows a credit balance of £8,096. 6s. 9d., which, with the balance of £619. 4s. 3d., brought forward from last account, and £1,339. 18s. 7d., the balance of premiums above referred to, makes the total amount to the credit of net revenue account... £10,055 9 7

After deducting interest on debentures	£2,214	0	0		
Placing to renewal and depreciation fund	1,500	0	0		
Writing off preliminary expenses	2,174	3	0		
And providing for the sundry small items shown	175	15	2		
				6,063	18 2
There remains a balance of				£3,991	11 5

The directors recommend that this should be applied to a payment of dividends for the past year of 6 per cent. on the preference shares and of 5 per cent. on the ordinary shares, leaving a balance of £666. 9s. 4d. to be carried forward to next account. During the year, extensive alterations, embodying the latest improvements in the arrangements of the generating and distributing plant, have been made at the company's Cheyne-walk station, which was acquired in 1893. This station is now in full work, and has capacity for considerable increase of plant. The new sub-station in Pavilion-road is also in complete working order. The number of lamps added in 1894 is 6,621, bringing the total on December 31 to 47,286. The 6 per cent. first mortgage debentures amounting to £30,000, issued in the early days of the Company, are repayable on September 29, 1895. There are also second debentures amounting to £6,900 outstanding, which are terminable at six months' notice. To enable the directors to make provision for the redemption of these debentures, and to provide capital for necessary extensions, the resolution included in the accompanying notice will be proposed to the shareholders for their sanction at the general meeting on March 5, 1895. It is with great regret that the directors have to record the death of their esteemed colleague Sir George R. Prescott. Mr. George N. Marten, a director of the London and South-Western Bank, has been elected to fill the vacancy, subject to the confirmation of the shareholders. The retiring directors are Major-General C. E. Webber, C.B., and Mr. George N. Marten, who, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Bros. and Co., also offer themselves for re-election.

BIRMINGHAM ELECTRIC SUPPLY COMPANY, LIMITED.

The following is the report of the directors to be submitted at the ordinary general meeting of the Company at the offices, Dale End, on the 7th inst.

Your directors have pleasure in presenting their fifth annual report and balance-sheet. The amount of net profit, including the balance of £409. 12s. brought forward from last year, is £5,609. 5s. 6d. Out of this your directors recommend the payment of a dividend of 4 per cent., absorbing £2,754. 18s. 6d., placing £1,602. 15s. 3d. to the credit of the depreciation reserve fund, and a further sum of £250 to the general reserve fund, carrying forward the balance of £1,001. 11s. 9d. to next year's account. On making the above appropriation, the total of depreciation, general reserve, and of undivided profits will amount to £6,864. 0s. 8d. There has been a steady increase in the Company's business during the past year. The total number of 16-c.p. lamps or their equivalent on order, at December 31, 1893, was 10,223, and on the same date in 1894 the number was 12,138. The additions since the close of the financial year have brought the number up to 12,551. Several motors have for some time past been working from the Company's system, and, with the reduced scale of charges for current used for this purpose, their general adoption is only a question of time as their convenience and economy become known. During the past year Parliament has confirmed the provisional order extending the Company's operations over Edgbaston and the jewellers' quarter. These areas should ultimately form valuable additions to the Company's business. The capital expenditure during the year amounts to £12,674. 1s. 1d., and includes a portion of the expenditure on account of buildings to complete the works at Dale End, the addition of new plant, and the extensions of mains and services. Your directors have acquired certain freehold and leasehold properties in Newhall-street and Monument-lane for works in connection with the new parliamentary areas, the cost of which forms part of the capital expenditure of the year; and, as they have made arrangements to at once carry out such portions of the works as may be necessary to supply these areas, it is proposed to shortly call up the balance of unpaid original capital. To further provide for the additions to the Company's business, the following resolution will be submitted to the shareholders—viz., "That the capital of the Company be increased by £100,0000, divided into 20,000 shares of £5 each (making the total nominal capital £200,000), to be issued at such times and on such terms as the directors may from time to time think fit." It is thought desirable that a quotation on the Birmingham Stock Exchange be obtained for the Company's shares, and with this object a resolution will be proposed authorising the directors to relieve members of the Birmingham Stock Exchange from the operation of Articles Nos. 24 and 25. In accordance with the articles of association, two directors, Mr. George S. Albright and Mr. G. H. Johnstone, retire by rotation, and are eligible for re-election. The auditors, Messrs. Sharp, Parsons, and Co., also retire and are eligible for re-election.

BALANCE-SHEET, DEC. 31, 1894.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Brentford.—The Urban District Council require tenders by the 12th inst. for the supply and fixing of telephones and electric calls in connection with the fire brigade. Further particulars will be found in our advertisement columns.

Llanelly.—The Borough District Council desire plans, designs, specifications, and estimates of cost for the supply and installation of electrical plant and machinery, including street lamps and laying down mains. Plans of the district can be obtained from Mr. George Watkeys, C.E, borough surveyor, Llanelly. The plans, etc., are to be sent to the clerk of the Council before the 25th inst. Details are given in our advertisement columns.

RESULTS OF TENDERS.

Norwich.—The Town Council have accepted the tender of Messrs. Laurence, Scott, and Co., at £458, for providing and fixing fittings for lighting St. Andrew's Hall by electricity.

Kingston-on-Thames.—The Town Council have accepted the tender of Messrs. Harrison, Cole, and Co. for establishing telephonic communication between the electric light station and the engineer's house.

BUSINESS NOTES.

Hove.—The Works Committee of the Urban Council do not at present favour street-lighting by electricity.

Eccles.—The Town Council have decided to carry out an electric lighting scheme at an expenditure of £20,000.

Blackpool.—The Corlett Engineering Company have received an order from the Corporation to supply two dynamos.

Alverthorpe (Wakefield).—It is the intention of the Parish Council of this village to light it either by gas or electricity.

Digitized by Google

Bradford.—The Gas and Electric Lighting Committee have under consideration a proposal to extend the electricity works.

Shrewsbury.—The work of laying the mains has been commenced by the Shropshire Electric Light and Power Company.

Pupil Required.—The engineer (Mr. J. E Stewart) to the Derby Corporation electric light station has a vacancy for an articled pupil.

Liverpool.—It is possible that the Corporation will call in the services of a consulting engineer to advise them on electric lighting matters.

United Ivy Mines.—A cablegram states that the new mill is in perfect order, but that Moodie's electric power plant is not yet quite completed.

Mersey Railway.—The Company are promoting a Bill to empower them to work their railway by electric or other motive power, and to raise additional capital.

Radcliffe.—A member of the District Council believes that there is sufficient water at the New-road Mill to produce electrical energy for the lighting of the district.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 24th ult. amounted to £847, as compared with £616 in the corresponding week of last year.

Office Alterations.—The Establishment Committee of the London County Council have authorised an expenditure of £20 for alterations to the electric light fittings at the central offices.

Aroscopic Lens Company, Limited.—This Company has been registered with a capital of £1,000 in £1 shares, to carry on business as manufacturers of and dealers in electrical, medical, and optical instruments.

Bournemouth—The Town Council have resolved to write to the electric supply company asking them to supply to the Council electrical energy for all purposes on the same terms as they supply to the winter garden.

Atcham.—The Board of Guardians have instructed the clerk to communicate with the telephone company and ascertain the cost of connecting the telephone with the workhouse and the medical officer at Shrewsbury.

City of London Electric Lighting Company.—Mr. J. Cecil Bull, the manager and secretary, informs us that the warrants for the dividends on the preference and ordinary shares of the Company have been posted.

Universal Governments' Army, Navy, and Commercial Manufacturing Company, Limited.—This Company has been registered, with a capital of £937. 10s., to erect rolling-mills, etc., and to manufacture machinery, dynamos, etc.

W. J. Robinson and Co., Limited.—This Company has been registered, with a capital of £40,000 in £5 shares, to acquire the business of electrical engineers now carried on, under the style of Messrs. A. J. Robinson and Co., at Liverpool.

Bellingwe Development Syndicate, Limited.—This Company has been registered, with a capital of £30 000 in £1 shares. to acquire lands, mines, etc., in South Africa or elsewhere, and to carry on business as electrical and general engineers.

New Electrical Firm.—Messrs. Wood and Co , of 74, Cheapside, London, E.C , have established a branch as electrical engineers for the carrying out of complete electric light and power installations. Mr. L. A. S. Wood is the consulting electrician.

John Crossley and Co., Limited.—This Company has been registered, with a capital of £5,000 in £5 shares, to acquire the business of engineers, ironfounders, etc . now carried on at Bank Bottom Mills, Halifax, Yorks., by Messrs. John Crossley and Co.

Tramcar Lighting.—The North Staffordshire Tramways Company propose to make their cars additionally attractive by lighting them by electricity. A similar decision has been arrived at in the case of the London, Deptford, and Greenwich Tramways Company.

Blackburn.—The Blackburn Corporation have decided to light the Town Hall by electricity, and have instructed Mr. E. M. Lacey, A.M I C.E., of 19, Old Queen street, Westminster, S.W., to prepare plans and specifications for the carrying out of the work.

Wandsworth, S W.—The District Board of Works have resolved to ask the Board of Trade to reconsider their decision sanctioning the use of transformer-chambers in the public streets by the electric lighting company proposing to supply the district with electricity.

Battery and Motor Company, Limited.—This Company has been registered, with a capital of £12,000 in £5 shares, to adopt an agreement made between H. T. Barnet and F. J. Moffatt for the purchase of certain patents relating to improvements in primary batteries and motors.

Newington, S.E.—The General Purposes and Lighting Committee of the Vestry have appointed Mr. A. E. Smithers and Mr. J. A. Dawes delegates to join the deputation to the Treasury for the purpose of getting the period for granting electric lighting loans extended from 20 to 42 years.

Bailey's No. 2 South Gold Mining Company, Limited.—This Company has been registered, with a capital of £100,000 in £1 shares, to acquire any gold mines, mining rights, and auriferous land in Western Australia or elsewhere, and to construct and maintain rail and tramways, telegraphs, telephones, etc.

New Showrooms.—Messrs. Wm. Whitehouse and Co., of Empire Works, Brueton-street, Birmingham, makers of gas and electric light fittings, have opened permanent showrooms at 59, Holborn-viaduct, London, E C., where they have on view samples of their newest designs in gas and electric light fittings, etc.

Swindon.—The Water Board desire to have erected a telephone between the Board's offices in Old Swindon and the Public Offices at New Swindon. The clerk has been instructed to obtain the cost of having a private wire connected with the exchange.

City and South London Railway.—The receipts of the Company for the week ended February 24 were £949, against £945 for the corresponding week of 1894, or an increase of £4 The total receipts for the current period of the present half-year are £7,988, against £7,610 in the corresponding period of 1894, an increase of £378.

Tamworth Gold Mining Company, Limited.—This Company has been registered, with a capital of £85,000 in £1 shares, for the acquisition of any gold mines, mining rights, grants, concessions, and auriferous land in New South Wales and elsewhere, and to construct and maintain tram and rail ways, telegraph and telephones, etc.

Electric Power in Engineering Works.—Messrs. Greenwood and Batley, Limited, of Albion Works, Leeds, announce for the benefit of those who are watching the developments of electric transmission of power in engineering works, that they have secured from a foreign Government a large order for machine tools with electric motors combined.

Business Announcement.—The Unbreakable Pulley and Mill Gearing Company, Limited, of Hyde-road Engineering Works, West Gorton, Manchester, inform us that they have appointed Mr. John Chorley, Buttermarket-street, Warrington, as their agent for the sale of their "unbreakable" wrought-iron pulleys, mill gearing, special steel shafting, "Gorton" gas-engines, etc.

Empire Economic Steam Producer, Limited.—This Company has been registered, with a capital of £80 000 in £1 shares, to adopt an agreement, made between R. Klostermann and O. Friederici and C. W. Williams, for the acquisition of certain letters patent relating to improvements in grates used in boiler furnaces, and to carry on business as ironfounders and mechanical engineers.

Halifax and Bermudas Cable Company.—An official notice has been given in the Private Bill Office of the House of Lords that the Halifax and Bermudas Cable Company, Limited, does not intend to proceed any further with its deposited Bill for this session. Under this Bill it was proposed to make further provision with reference to the investment of the subsidy payable to the Company by her Majesty's Government.

Kingswood (Bristol).—A letter has been read at a meeting of the Kingswood District Council from the Bristol electrical committee, stating that the surveyor to the Kingswood Council might visit the Bristol central station with a view to obtaining any information he could as to the manner in which testing lights can be carried out. It was decided that the chairman, the surveyor, and Mr. A. Evans should visit the works in Bristol.

Cardiff—The Joint Standing Committee of the Glamorgan County Council had brought under their notice on Monday by Councillor Jotham the question of introducing the electric light into the County Offices. Mr. O. H. Jones said that the electric light in Cardiff was in a state of confusion. He thought that until they had the electric light in working order the county had better leave it alone. Alderman Rhys moved that the matter be postponed for six months, the motion being agreed to.

Kingston-on-Thames.—It appeared from the minutes of the Lighting and Market Committee, presented to the Town Council last week, that Major General Crozier had been appointed by the Local Government Board to hold an enquiry at the Town Hall last Monday in reference to the application by the Corporation for sanction to borrow an additional £10,000 for electric lighting purposes. The Town Council have decided to allow discounts ranging from 2½ to 10 per cent. It is probable that the post office will be lighted by electricity. The enquiry was duly held.

Bath.—The minutes of the Electric Lighting Committee presented to the Town Council last week contained a reference to the fact that the authority had decided to oppose the application of the electric light company for a provisional order by applying for one itself. The Mayor said he had asked the clerk what had been done, and he was told that at present nothing further could be done. Alderman Sturges said the Board of Trade had had informal notice of the intentions of the authority. Mr. Radway hoped the clerk would not allow the matter to slide too long, and it was decided that an early meeting of the Electric Light Committee should be called.

Killarney.—A report was presented last week to the governors of the district lunatic asylum stating, in regard to the lighting of the asylum, that the Killarney Electric Light Company had written a letter to the effect that they are prepared to lay the connecting mains from the distributing station in the town, including the construction of a transformer-house at the asylum end to the specification, and under the supervision of the consulting electrical engineer acting on behalf of the directors. The governors decided to approve of the installation of the electric light in lieu of gas, and requested Mr. Leake to prepare plans and specifications to enable them to advertise for tenders.

Southampton.—Attention was drawn at a meeting of the Harbour Board last week to the delay in completing the electric lighting contract at the Town Quay, the time for which was stated by the electrical engineer (Mr. J. G. W. Aldridge) to have expired. The clerk had been instructed to write to Messrs. Crompton and Co. calling their attention to the matter. Messrs. Crompton and Co. wrote, in reply, expressing regret that the Works Committee should feel dissatisfied that their contract was not quite completed. They urged that they had had some difficulties which

Digitized by Google

were quite unexpected, and that no effort would be spared to get the work completed and out of hand.

Brighton.—The minutes of the Lighting Committee presented to the Town Council last week reported with reference to negotiations with the owners and lessees of 39, North-road, with a view to the purchase of those premises for the extension of the electricity generating station. It was resolved to accept the offer made and to apply to the Local Government Board for sanction to borrow £750 for 40 years to defray the cost. The manager was instructed to purchase at the sale of the plant belonging to the Brighton and Hove Electric Light Company, Limited, such articles as he deemed necessary for the Corporation electricity installation at an expenditure not exceeding £500. The Town Council confirmed the minutes.

Yeadon.—A special meeting of the Yeadon District Council has been held for the purpose of discussing the electric light question. Mr. James Flaxington, after a lengthy speech on the advantages of electric lighting, proposed that the Council call in an expert electrician to examine and report upon the tenders which had been sent in to the Council for the lighting of Yeadon by electricity. Mr. Herbert Marshall seconded the proposition. Mr. John Cooper opposed the motion, on the ground that electric lighting for Yeadon would not be a profitable undertaking, and moved, as an amendment, that the Council abandon the project altogether. The amendment was not seconded, and Mr. Flaxington's motion was carried.

St. Luke's, E.C.—The St. Luke's Vestry have been in correspondence with the Board of Trade on the subject of transformer-chambers under the footpath. It appears that the late surveyor of the parish pointed out that the gas-mains in the City-road were defective and that gas was continually escaping, and that at any moment a serious explosion might occur. Major Cardew, who had inspected the works with the engineer of the electric light company, stated that the company were willing to put clean shingle in the boxes in order to prevent an accumulation of gas. The Vestry agreed that this should be done in cases where it was possible, but decided to insist upon proper ventilation of the larger street boxes used as converting stations.

Appointments Vacant.—The Corporation of Cardiff are about to appoint a practical man to take charge of their electric lighting station at Canton, under the general supervision of the borough engineer, and invite applications for the post. Applicants must be experienced in electrical work and engine fitting, and have had actual experience in the charge of a high-pressure alternating system at an electric lighting station. The salary offered is £200 per annum Further particulars of the duties may be obtained on application to Mr. W. Harpur, borough engineer, Town Hall, Cardiff. Applications are to be delivered at the office of Mr. J. L. Wheatley, town clerk, Town Hall, Cardiff, by 7th inst. The Corporation of Walsall invite applications for the position of electrical engineer at the electric lighting station. The salary offered is £150 per annum. Applications are to be sent to Mr. John R. Cooper, town clerk, before the 16th inst. Further information is contained in our advertisement columns.

Birmingham.—The Technical School Committee of the Town Council will present a further report to the Council on Tuesday, furnishing additional particulars respecting the proposed expenditure of £14 000 upon the educational and other fittings in the new school, and £6,271. 8s. for lighting the school by electricity. At the last meeting of the Council the committee's recommendation as to lighting by electricity was criticised, and it was pointed out that the gas department tendered to light the school with ordinary flat-flame burners for £892. 17s , and with incandescent gas burners for £1,382 17s. The further discussion of the report was adjourned, it being understood that the committee in the meantime would provide the Council with other details as to their proposed expenditure. These details are contained in the report now issued. Six firms tendered for the equipment of the 116 rooms of which the new school will consist, the tenders varying from £20,510 to £13,226. It was resolved that the latter, that of Messrs. Parker, Limited, should be accepted. A revised specification was, however, issued. To the revised specification 29 tenders were received, and, subject to the approval of the Council, the committee purpose accepting the tender of Messrs. D. and G. Graham, of Glasgow, at the sum of £5,515. 14s. 2d. For the ornamental and other fittings, which were not included in the revised specification, it is estimated that a sum of £565 will be required, which sum, added to the amount of Messrs. Graham's tender, will make a total expenditure on this head of £6,080. 14s. 2d.

Leeds Tramways.—A deputation from the Leeds City Corporation had an interview with Mr. Bryce, President of the Board of Trade, at the House of Commons last week, to solicit his assistance in facilitating by the suspension of the standing orders the passage through Parliament of the Bill promoted in the House of Lords by the Corporation for the extension of the city tramways, and making provision for electric or other traction. The proceedings took the form not so much of set speeches as of general discussion, in which the arguments on behalf of the corporations were stated, and the matter thoroughly gone into. It was pointed out that only two corporations possess working powers such as the Leeds Corporation desire to obtain—namely, the Glasgow Corporation and the Huddersfield Corporation. Not caring to work under a license which might be withdrawn at any time, as in the case of Huddersfield, the Leeds Corporation desire to possess statutory powers to work the tramways without being called upon to let them except by a resolution of the Corporation itself. The President of the Board of Trade, as the London County Council have a similar Bill before the House of Lords, suggested that the Leeds Corporation should wait until they saw what was done with that Bill at the committee stage. At the close of the discussion, Lord Playfair suggested that the chairmen of committees for the House of Lords and House of Commons should confer together on the matter, feeling qnite sure that if they could only agree to a suspension of standing orders, this advice would have great weight with both Houses of Parliament.

Bankruptcy Proceedings.—An application was made last week at the London Bankruptcy Court to Mr. Registrar Hope for an order of discharge on behalf of William David Gooch, electrical engineer, formerly of Victoria-mansions, Westminster. The bankrupt attributed his failure chiefly to loss on contracts for lighting by electricity various exhibitions. He also had a contract for three years at Manchester for electric lighting. In connection with that contract he made a loss of £300 a year, and only got out of it by giving up the machinery. Mr. H. Brougham. the official receiver, reported that the accounts showed ranking liabilities £4,365, and no available assets. Proof to the amount of £2,147 had been lodged with the trustee. The bankrupt carried on business on his own account from 1885 to 1888, during which time he incurred the bulk of the indebtedness in connection with speculative electrical contracts, etc. Mr. B. Dennies appeared for the bankrupt in support of the application, and offered to have judgment for £150 entered against the bankrupt as a condition attaching to the discharge. After hearing the case, the learned Registrar said such an offer could not be entertained, as it was simply sanctioning a scheme for the payment of less than 7s. 6d. in the pound. He regarded the offence of insufficient assets in a rather serious light, seeing that the debts amounted to £4 300 and there were no assets. It had been urged that £1,000 of those liabilities were put upon the bankrupt in connection with the Oldham exhibition under circumstances of a misleading nature to the bankrupt. Allowing for the deduction of that sum, there was still a deficiency of over £3,000. It was clear that the bankrupt had undertaken electric lighting contracts without having sufficient funds at his command to carry them through with success. Having regard to all the circumstances of the case, the order of discharge would have to be suspended for three years.

Private Installations.—The contract for lighting the new Isle of Wight County Asylum has been obtained by Mr. F. Shalders, of High-street, Southampton The plant will consist of engine and dynamo for the heavy load, engine and dynamo for charging battery and for use as reserve, switchboards, steam-pipes, and wiring for about 800 lamps. Mr. Shalders is now putting down an installation at Fen Place, the residence of Mr. J. Stewart Oxley. The plant comprises engine and dynamo, accumulators, motors for pumping, churning, and cream separating, switchboards, and wiring for about 200 lamps. He is also wiring throughout the new County Offices, Winchester, for about 120 lamps. A complete organ-blowing plant for the Church of St. Lawrence, Southampton, has been installed by Mr. Shalders. The power for driving the motor is obtained from the local supply company's mains. The supply and regulation of wind are perfect in every respect, and give extreme satisfaction. This plant was designed and laid down by one of his assistants, Mr. T. Davis, who also superintended the installations previously mentioned. Messrs. Bennett and Druce, of Preston, have just completed an electric light plant for the St. Joseph's Church and Canon Walmsley's house, Preston. The installation consists of nearly 150 lights, complete with Crossley gas-engine, shunt-wound dynamo, and accumulators. In this installation the light is taken from the accumulators solely, the engine and dynamo being used simply for charging the latter. The firm have also received instructions to proceed with the electric lighting of the three-storeyed sheds at the Manchester Ship Canal Company's Salford Docks, where about 500 lamps of 32 c.p. and 50 c.p will be required. The lighting of the new Farmer's Arms Hotel, Preston, has also been entrusted to this firm. About 150 lamps will be installed, the current being taken from the Supply Company's mains.

Acton, W.—The District Council last week again discussed the question of the application of the London United Tramways Company for the Council's sanction to their project to carry their tramway to Acton-hill. Messrs. Walter Webb, the solicitor to the company, Mr. White, the chairman of the directors, and Mr. Kincaid, the engineer, have had several interviews with the Council on the subject. At present the company are empowered to double their line from the Shepherd's Bush boundary to Birkbeck-grove, at Acton, and to relay the whole of the present line with granite setts. What they desired to do, in addition, was to double the line from Birkbeck-grove to Birkbeck-road, with interlacing under the railway arch, and to carry a single line from Birkbeck-road to the top of Acton-hill. The offers made by the company were not considered by the Council to be sufficient, and the tramway people were reminded that the Council and the County Council had spent £20,000 in the widening of the High-street, which had made the proposed extension possible. After consideration the Council asked the company to pave the whole of the present and proposed track with hard wood, and to make a money grant of £1,000 to the Council in exchange for the concession of the sanction of the Council to the extension. Having deliberated with his colleagues, Mr. White said the company would make the money grant, but were not prepared to adopt wood paving throughout their line until they were permitted to use electric instead of horse traction. These terms the Council declined to accept, and it was suggested that the company should consent to repave the whole of their track

Digitized by Google

with wood whenever the Council undertook the wood-paving of the rest of the road. This suggestion was not accepted, and ultimately the promoters of the undertaking were asked to decide between the extension, plus the wood-paving of the whole track, or no extension. Mr. White then intimated that if these were the minimum terms of the Council the company must abandon the extension project for the present. As neither side had further propositions to submit, the matter ended. The Council definitely decided not to consent to the extension.

FEBRUARY 18.

3458. **Improvements in and connected with arc lamps.** John Brunswick Barton, 18, Southampton-buildings, Chancery-lane, London. (William Jandus, United States.)

3511. **An improved method of electrically signalling upon railways.** John Wesley Courtis, Frederick Parker Sibley, and Charles Dallimore, 22, Southampton-buildings, Chancery-lane, London.

3512. **An apparatus for electrically communicating from a fire-engine to a fireman in charge of hose on building.** John Wesley Courtis, Frederick Parker Sibley, and Charles Dallimore, 22, Southampton-buildings, Chancery-lane, London..

FEBRUARY 19.

3548. **Improved electric switch.** William Edge, 25, Tabard-street, Borough, London.

3573. **Improvements in telephonic apparatus.** Norval Landon Burchell, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

3582. **Improvements in casings for electricity conductors.** Henry Reason, 111, Gloster-road, Brighton.

3593. **Improved wire draw vice and key, particularly intended for use in telegraph and telephone wire line work.** William Broomhead Shaw, 22, Glasshouse-street, Regent-street, London.

3622. **Improvements in electric dental engines.** William Eugene Wheeler, 53, Chancery-lane, London.

3625. **An improved process for coating or plating metals with aluminium or aluminium alloys by electrolysis.** Carl Oppermann and Ernest Bailey, 2, Wynyatt-street, London.

FEBRUARY 20.

22965A. **Improvements in the method of and apparatus for electrically heating metal or other conducting bodies.** William Phillips Thompson, 6, Lord-street, Liverpool. (Charles Lewis Coffin, United States.) (Date claimed under Patents Rule 19, November 27, 1894.) (Complete specification.)

3633. **Improvements in or connected with the distribution of electricity.** Thomas Parker, John Harold Woodward, and Edmund Scott Gustave Rees, Wolverhampton.

3662. **Improvements in electrical contacts for torpedoes.** Joseph Rogerson Scott, Akenside-hill, Newcastle-on-Tyne.

3679. **Improvements in the construction of electric arc lamps.** Thomas Sedgwick Foster, 18, Buckingham-street, Strand, London.

3685. **Improvements in the insulation of electric conductors.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

3687. **Improvements in or relating to electric traction.** Wilfrid Swanwick Boult and Cedric Randal Boult, 323, High Holborn, London.

3693. **New and improved electric lock and system of electric locking for the purpose of securing additional safety in railway signalling.** James Frederick Walter Morris and George Mumford, 20, Grummant-road, Peckham, London.

3701. **Improvements in electrical driving gear for vehicles.** Walter Charles Bersey, 53, Chancery-lane, London.

FEBRUARY 21.

3770. **Improvements in or connected with the filaments of incandescent electric lamps.** Jesse Graham and Harry Chapman, 33, Chancery-lane, London.

3779. **Improvements in economising apparatus for the carbons of electric arc lamps.** Alfred Albrecht, 40, Chancery-lane, London. (Complete specification.)

3788. **Improvements in electric locomotives chiefly designed for use in mines.** Bruno Lebrun, 45, Southampton-buildings, Chancery-lane, London.

FEBRUARY 22.

3809. **Improvements in electric and galvanic batteries and accumulators.** Joseph Baxeres Torres, 13, Golden-square, London.

3812. **Improvements in electrical switches or circuit closers.** Meyer H. Goldstone and James H. Ward, Gorton Brook Electric Works, Manchester.

3821. **A new form of alternating-current dynamo-electric generator.** James Finlayson, 114, West Nile-street, Glasgow.

3841. **Improvements in the method of and apparatus for ventilating manholes, electric light boxes, and underground chambers or cellars of all sorts.** George Hinde Nisbett, 6, Lord-street, Liverpool.

3864. **Improvements in power gearing and current-controlling apparatus for electric cars.** Elmer Ambrose Sperry, 40, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, July 24, 1894, being date of application in United States.) (Complete specification.)

3866. **Improvements in electrical switches.** Reginald Wilmot Hayes Newington and Richard Hewlett, 1, Queen Victoria-street, London.

3874. **Improvements in adjustable electric lights.** Alexander Leslie Fyfe, 22, Southampton-buildings, Chancery-lane, London.

FEBRUARY 23.

3903. **An improvement in electrical conductors.** Hugh Donald Fitzpatrick, 70, Wellington-street, Glasgow. (The Electric Bell and Resistance Company, United States.) (Complete specification.)

3954. **Improvements in and relating to telephone systems.** Salomon Berditschewsky (called Apostoloff), and Moïse Freudenberg, 45, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1890.

9361. **Electric reduction of metals.** Willson. (Third edition.)

1892.

21696. **Electric smelting of ores, etc.** Willson. (Second edition.)

1894.

1903. **Secondary battery electrodes.** Wuillot.

2493. **Electric lampholders.** Randell.

2730. **Protector for electric cables.** Grant.

25076. **Telegraphic transmitters.** Boult. (Spiro.)

1895.

56. **Electrical cut-out.** Siemens Bros. and Co. (Siemens and Halske.)

157. **Telephone call stations.** Jensen. (Jacobsen.)

NOTES.

Private Bills.—The Leeds Corporation Tramways Bill was read a second time in the House of Lords on Monday.

Chemical Society.—The anniversary dinner of this society will take place at the Hotel Metropôle on Wednesday, the 27th inst.

Battersea Polytechnic.—The annual distribution of prizes and certificates in connection with this institution took place on Wednesday night.

Institution of Electrical Engineers.—Mr. N. S. Keith, member, will read a paper on "The Electrolysis of Gold" before this Institution on Thursday next, the 14th inst.

Institution of Mechanical Engineers.—The summer meeting of this institution will be held in Glasgow. The meeting will commence on Tuesday, July 30, and will last four days.

Thames Valley.—A committee of the Conservators of the River Thames have resolved to consider a suggestion that the locks in the Thames valley should be connected either by telegraph or telephone.

Telegraphy between Burma and Siam.—The Indian Government have sanctioned a survey for a telegraph line from Mone in the Shan States to the buffer State on the Siam frontier.

University Examiners.—The Senate of the University of London, on April 24, will elect examiners in various departments, including two in mathematics and natural philosophy and two in chemistry.

Electro-Culture.—The members of the Wolverhampton Gardeners' Mutual Improvement Society met on Wednesday at the Midland Café, Queen's-square, when a lecture was delivered by Mr. G. W. Fairall upon "Electro-Culture."

Smoking Concert.—The third annual smoking concert of the employés of Messrs. Drake and Gorham was held at Cloot's Restaurant, Victoria-street, S.W., on Wednesday evening. A very pleasant programme was provided.

Transmission of Power.—The Italian Minister of Agriculture and Commerce has appointed a commission to investigate the law passed last year relating to the electrical transmission of energy over long distances for industrial purposes.

Sydney.—In the prospectus issued this week of the Sydney Harbour Collieries, Limited, it is mentioned that it is proposed to sell the small coal for steam-raising purposes in connection with the electric lighting of Sydney, New South Wales.

Utilisation of Refuse.—In the course of a lecture delivered last week by Mr. P. Fyfe, sanitary inspector of Glasgow, the speaker gave an outline of a system under which the city refuse could be utilised for raising steam in connection with electric lighting.

National Exhibition.—Preparations are being made to hold a National Exhibition of Industry and Fine Arts in the city of Mexico, to be opened on April 2, 1896. Though the exhibition is termed national there will be a foreign department, to which it is expected that foreign nations will contribute.

Protection of Electrical Conductors.—A description, together with illustrations, is given in the *Elektro technische Zeitschrift* of February 21 of a device introduced by Messrs. Richard Hegelman, of Erfurt, as an auxiliary to lightning protectors, so as to safeguard from the effects of heavy currents conductors carrying weak currents.

Powdered Lead Accumulators.—Referring to the article on this subject published in our last issue, Mr. G. Straus, of 130, Queen Victoria-street, E.C., writes that he is the sole agent for the United Kingdom for the patentees, and that he is open to entertain proposals for the manufacture of the batteries or for disposing of the patents.

United States Patent Law.—The Supreme Court in Washington, in giving its decision on Monday in the Bate refrigerator case, held that the date of the issue of a patent, and not the date of application for such patent, determines whether patent rights in the United States expire simultaneously with the patent rights secured abroad.

Madras Electric Tramways.—A trial trip with a car was made recently from the power station at Egmore as far as the Madras Ice Factory. The *Indian Engineer* states that the car was in charge of Mr. Gadsby, the electrician of the company, who fitted the car with small temporary lamps. The car ran at the rate of about eight miles an hour.

Lecture.—An interesting lecture on recent advances in electrical applications was delivered on Monday at Stoke Newington by Mr. Fred H. Taylor, A.I.E.E. The lecturer dealt with heating and cooking by electricity, transmission of power, electric bleaching, electric welding, traction, signalling through space, electrically-operated musical instruments, etc.

Northern Society of Electrical Engineers.—A meeting of this society will be held on Monday next, the 11th inst., at the University College, Liverpool, commencing at 7 p.m. Mr. F. G. Baily, M.A., member, who will read a paper on "The Scientific Principles of Electrical Engineering," will allow his laboratory to remain open for the inspection of members previous to the meeting.

Institution of Civil Engineers.—The monthly ballot on Tuesday resulted in the election as members of Messrs. A. Crombie Humphreys, Westminster; Basil Mott, A.R.S.M., Stockwell; F. J. Sprague, New York; and A. W. Willet, L. and N.W. Railway; and the associate members elected included the names of Messrs. John Hesketh, of Blackpool, and H. Field Parshall, of Westminster.

Private Bill Legislation.—The Standing Orders Committee have decided to dispense with the standing orders in the case of the petition of the Cork and Fermoy Railway Company and of the petition of Baron Ardilaun against the Dublin United Tramways Bill. The Vestry of Lambeth have presented a petition against the proposal of the City and South London Railway Company to extend the time for carrying their underground electric railway forward to Clapham.

Royal Institution.—Among the members elected at the meeting on Monday were the Duke of Newcastle, Lieutenant-Colonel W. W. Rawes, R.A., Dr. Marmaduke Prickett, and Messrs. G. S. Albright, E. G. Betts, R. A. Bray, M. Bullock, G. Bywaters, G. F. N. Clay, C. S. Dickson, J. J. Elliott, J. Garvie, F. L. Harris, E. G. Harrison, S. C. Hogg, E. Law, G. H. Ogston, B. P. Portal, S. J. Portal, W. T. Shaw, J. H. Skelton, J. J. Walker, W. H. Walker, and A. F. Walter.

Storage Battery Traction.—Following the example of London, Paris, and Brussels, Berlin is now to be the scene of experiments with accumulator cars. The tests are to be made on the line from Moabit to Grossgörschen-

Digitized by Google

strasse. Brussels, however, is not content with the unsatisfactory results obtained with the Julien system a few years ago, as is shown by the fact that a commission, consisting of officials of the Belgian State Railways, have inspected the Hagen Accumulator Works, and propose to introduce the zinc-copper batteries into Belgium for traction purposes.

Institution of Engineers and Shipbuilders.—The sixth general meeting of the present session of the North-East Coast Institution of Engineers and Shipbuilders will be held in the lecture hall of the Subscription Literary Society, Fawcett-street, Sunderland, on Tuesday next, the 12th inst., at 7.40 p.m. The discussion will be concluded on Mr. W. C. Mountain's paper on "The Design and Efficiency of Plant for the Transmission of Power by Electricity," and Mr. Henry Foster's paper on "The Application of the Electric Arc to Machinery and Boiler Repairs" will be discussed.

Telegraphic Interruption.—Not for years, the *Daily News* states, has telegraphic working with the Continent suffered from such a series of mishaps as that which has marked the present winter. On Tuesday it was reported at St. Martin's-le-Grand that the cable from Beachy Head to Dieppe had been severed, this being the fifth cable to break down within a period of only a few months. Continental telegrams had for a considerable time past been subject to delay on account of the few wires available, and the consequent necessity of diverting the traffic over indirect routes, and this latest casualty has added seriously to the difficulty of prompt despatch.

Explosions in Underground Mains.—The following letter from Mr. L. Epstein appears in the *Standard* of yesterday: "A possible explanation for the deposit of the metallic sodium, which, according to Major Cardew's report, has caused the recent explosions, may be found in the following hypothesis. Assuming that the glazing of the earthenware insulators has been produced by the usual material—viz., common salt (which forms a silicate of sodium with the unglazed material)—is it not possible that the leakage current between positive and negative mains, across the earthenware insulators, sets up electrolysis, resulting in the deposition of the metal sodium from its silicate?"

Determination of the Resistance of Electrolytes.—Prof. G. Kohlrausch criticises in the *Zeit. Physikal. Chem.* the method employed by Wildermann, an abstract of which is given in the *Journal* of the Chemical Society. The author is of opinion that the telephone method with alternate currents can be employed for much higher resistances than those examined by Wildermann, and is more convenient and simple than the method of the latter, which involves the use of strong batteries. In the cases of much higher resistances, 100,000 ohms and more, he does not consider Wilderman's method sufficiently accurate to render its application useful.

Forthcoming Lectures.—A special course of four lectures on electric light wiring will be delivered in the Heriot-Watt College on Monday evenings at seven o'clock, commencing on Monday next, the 11th inst., by Mr. R. Mullineux Walmsley, D.Sc., F.R.S.E., etc., professor of electrical engineering. The points considered will be those of importance to wiring contractors and to householders and others who propose to take advantage of the public supply of electric current by the Edinburgh Corporation. The first lecture will deal with conductors and circuits (rules for safety); the second with positions and fixing of conductors; the third with switches, fuses, and other small fittings; and the fourth with lampholders, brackets, and electroliers.

Terrestrial Magnetism.—The Royal Astronomical Association listened last week to a paper by Mr. Adams on "The Connection between Variations of Terrestrial Magnetism and Solar Surface Disturbances." Father Cortie (Stonyhurst Observatory) said that probably the sun-spots were only one manifestation of some agency at work in the sun. Though Lord Kelvin had, he believed, proved mathematically that it was impossible that outbursts on the sun could affect the earth magnetically, yet it was possible that both the solar disturbances and the disturbances of terrestrial magnetism might be effects of one cause. He had found that it was spots of a particular kind that accompanied magnetic storms, the position of the spot having no effect.

The Proposed Hawaiian Cable.—A telegram from Washington on Monday stated that the Senate has passed a resolution declaring that it still adheres to its amendment voting 500,000dol. for the Hawaiian cable, but that the House of Representatives persists in refusing to agree to it. In opposing the cable project in the Senate, Mr. Pettigrew, member for South Dakota, said: "Let Great Britain lay the cable; there is no reason to fear her." Mr. Morgan, in supporting the scheme, declared that Great Britain proposed to extend her dominion to Hawaii, and opposition to the cable meant only that the United States should yield to Great Britain to enable the latter to obtain the dominion. A subsequent despatch states that the Senate has withdrawn the amendment to the Diplomatic Appropriations Bill providing for the sum of 500,000dol. for the laying of a cable to Hawaii, thus definitely killing the project.

Electric Athletes.—A festive throng gathered on Friday at the Holborn Town Hall, a considerable portion of those present being members of the Electric Athletic Association in connection with the Central Telegraph Office, St. Martin's-le-Grand. The occasion was the annual distribution of prizes, together with an attractive entertainment made up of a long programme of music. The association consists of several of the clubs which, until a couple of years ago, had each a separate existence in connection with St. Martin's-le-Grand and its branches, but which were then amalgamated. The Postmaster-General (Mr. Arnold Morley, M.P.) was unable to be present, but among those who attended were Mr. Fischer, Mr. W. H. Preece, Mr. Lewin Hill, Mr. J. T. Hill, Mr. A. Askins, Mr. W. Wright, Mr. A. J. V. Adams, Mr. G. C. Newbury, the hon. general secretary and treasurer, Mr. F. J. Gilliver and Mr. E. Menzies, hon. assistant secretaries, etc.

Railway Rates.—The President of the Board of Trade stated, in reply to a question in the House of Commons on Monday, that about 1,800 complaints had been filed against increased railway rates by traders. Many of these, however, contained complaints from a number of traders against more than one railway company, and in most of them a number of rates was involved. The principal permanent officers of the Department had been engaged in dealing with the cases, but the pressure of work was so great that he had appointed Mr. Pelham, who was recently employed in connection with the revision of canal tolls and charges, to assist the Department. The Board of Trade were using their best endeavours to consider those complaints as expeditiously as possible in order that in those cases in which no amicable settlement could be arrived at, traders might be able to lodge their complaint as soon as possible with the Railway Commissioners.

Personal.—Mr. Frank B. Lea will be glad if correspondents will address him at 2, Rue de la Republique, Rouen, where communications may be sent to him for the next few months, during the conversion of the Rouen

Digitized by Google

tramways to electric traction. Mr. Lea is acting as resident engineer for the Tramways Electric Traction Company, Limited, who have a controlling interest in the Rouen system.—Mr. H. W. Kolle resigned on the 1st inst. his position as chief of the staff of Messrs. Ferranti and Co., Limited, in order to take up an engagement with the Babcock and Wilcox Company. As a mark of great esteem, a handsome massive silver salver was presented to Mr. Kolle by the employés, the presentation being made in a kind speech by Mr. Ferranti, who expressed regret at his leaving and best wishes for success.—Mr. A. S. Blackman, who has been in charge recently of the Aberdeen station, has now been appointed electrical engineer in place of Mr. Ruthven Murray, who resigned.

Light Railways.—It is stated that in the Bill which the President of the Board of Trade hopes to introduce this week, the Government will propose to give effect to the principal suggestions made by the committee of the recent conference on light railways. The measure will enact that proposals for the construction and working of light railways and tramways, especially in the case of lines built through sparsely-populated and agricultural districts, should be submitted in the first instance to the county council (with exceptional provisions as to large municipalities). In cases of compulsory acquisition of land, the report continues, there is to be a power of appeal to the Board of Trade. If any doubt arises as to whether a railway is a light railway, to be dealt with locally, or is a scheme which should properly be dealt with by Parliament, the Board of Trade is to determine the question. No provisions are made in the Bill as to the gauge of the proposed light railways, which may differ in different parts of the country, and no proposal is made to empower local authorities to contribute funds towards undertakings of that character.

Metric System of Weights and Measures.—The Select Committee of the House of Commons on the subject of weights and measures sat again on Tuesday, Sir H. Roscoe presiding. Mr. Chaney, of the Standards Department, Board of Trade, gave further evidence. He stated that the Board of Trade were authorised to verify metric weights and measures for purposes of science and manufacture, but not for trade. A manufacturer might for the purposes of his manufacture use metric weights and measures, but, on the other hand, he was liable to the consequences of his act if he used them for the purposes of trade. The inspectors had power to interfere with any existing weights of illegal denomination. Mr. Amos Dowson, C.E., chairman of committee of the New Decimal Association, referred to the educational aspect of the question. The scholars in our primary schools were being taught the principles of the metric system on the assumption, as he observed, that it would be adopted in this country. He gave some curious examples furnished by the secretary of the Nottingham and Midland Merchant Traders' Association and others of discrepancies in existing local standards. The witness also gave it as his opinion that the adoption of the metric system would be an advantage to our foreign trade. Our merchants were placed at a disadvantage because foreign customers preferred to deal according to the metric system, with which they were familiar.

Institution of Junior Engineers.—A number of the members of this institution availed themselves on the 23rd ult. of the opportunity afforded by the president, Mr. Alexander Siemens, for visiting Messrs. Siemens Bros. and Co.'s works at Woolwich. Special arrangements had been made for their guidance over the extensive works, which cover an area of 7½ acres, and the occasion was rendered exceedingly interesting in every way. The new and old dynamo shops, the milling, bobbin, fitters', and rubber shops, the central power and lighting station, the switchboard erecting-room, the cable shop, tank-houses, lead-cable shop, cable testing, instrument calibrating, and show rooms were seen. At the conclusion of the inspection, the members were hospitably received by the president, who expressed the pleasure he felt in meeting them, and the chairman, Mr. H. J. Young, conveyed the thanks of the institution for the facilities extended in connection with the visit. On Friday last a meeting of the institution was held at the Westminster Palace Hotel, Mr. Young presiding, when a paper on "Locomotive Repairing Work" was read by Mr. A. H. Newsam Smith, member, of the Great Northern Railway repairing shops, King's Cross. By permission of Mr. S. W. Johnson, locomotive superintendent, the members of the institution will visit on Saturday next the goods station and depôt and repairing shops of the Midland Railway, at St. Pancras and Kentish Town.

Electrolytic Dissociation.—Mr. S. Tanatar, in the *Zeit. Physikal. Chem.*, an abstract of which appears in the Chemical Society's *Journal*, says that the decrease of conductivity of salts by the addition of alcohol is ascribed, not to a decrease in the dissociation, but to the increase of the ion friction. Addition of alcohol, however, also caused a decrease in the inversion velocity of sugar by salts, although this is dependent on the dissociation only. The author, therefore, attempts to estimate, by means of the thermal effects, the dissociation changes caused by alcoholic dilution. In all cases the thermal effects due to the water alone are observed simultaneously, and allowed for in the results. The addition of a 2N solution of hydrochloric acid to an equal volume of alcohol produces a heat absorption of only 0·137 Cal., so that the 2N solution in water and the 1·03N solution in 44 per cent. alcohol appear to be approximately equally dissociated. The addition of 300c.c. alcohol to 250c.c. of a 2N solution produced a development of about 1·02 Cal., apparently indicating increased dissociation. Potassium chloride dissolved in alcohol gives rise to a greater heat absorption than in water, the quantity being determined, both indirectly and directly, with concordant results. This effect is not an exceptional one, the same result obtaining with alcoholic solutions of potassium nitrate, sodium chloride, cane sugar, acetic acid, and methylic alcohol, whilst it is also noticeable that the freezing point depression with potassium chloride is greater in dilute alcoholic than in aqueous solution.

Electric Traction at Bristol.—The construction has been commenced this week of the trolley line from the present terminus at St. George to Kingswood, where it will end near the King's Arms Hotel. Many months have been spent in making preparations for the work, particularly in dealing with frontages and widening the road, so as to meet the Board of Trade requirements, and to provide double lines as much as possible. Now everything is ready the line will be rapidly constructed. The contract for the electrical equipment of the line between Kingswood and Old Market-street has been let to the British Thomson-Houston Company. The existing depôt of the Bristol Tramways Company at St. George's is to be used for a generating station, and the alteration and reconstruction of the buildings necessary to receive the plant have been entrusted to Mr. A. J. Beavan. Mr. A. Krauss has accepted the contract to make the line between St. George's and Kingswood, and to do the necessary relaying and alterations of the present track from St. George's to Old Market-street. In Old Market-street the proposal is to place ornamental standards in the centre of the road, between the outward and inward lines, to carry double brackets of an ornamental type. If deemed advisable,

Digitized by Google

these standards may be used by the Corporation for their arc lamps. Everything was ready on Monday morning to make a start with the extension of the line from the St. George's terminus. The alteration of the existing line between St. George's and the city is to be taken in hand within a month, and its adaptation will go on concurrently with the construction of the new section of the line. The doubling and bonding are to be done chiefly at night, so that the traffic may not be interfered with. The major portion of the electrical plant is being imported from America. The cost of the whole work and appliances will be £50,000. The cars are to carry 50 passengers, to have outside garden seats, and to be illuminated outside and inside by electricity, the light to be sustained by means of storage cells, while the cars travel downhill by gravitation. The directors of the company are considering the advisability of introducing stopping-places, so as to save time and to ensure punctuality.

Electromotive Force of an Iodine Cell.—A paper on this subject was read recently by Mr. A. P. Laurie, M.A., before a meeting of the Chemical Society. A cell consisting of a zinc and platinum plate, immersed in a solution of iodine in potassium iodide, gives a definite and constant E.M.F., the zinc being dissolved at the expense of the iodine surrounding the platinum plate. On diminishing the strength of the iodine solution the E.M.F. gradually falls off, the rate increasing as the iodine becomes very dilute—the E.M.F. for a 0·1 per cent. solution being 1·460 volts, and for a 0·001 per cent. solution 1·369 volts. If potassium iodide free from iodine is used, an E.M.F. of about 1·172 volts is obtained. This value is uncertain, and varies for different platinum wires and at different times for the same platinum wire, the highest value being obtained with a wire boiled in soda, then in nitric acid, then washed, and finally heated white hot. If this wire, however, is left in the solution it gradually falls in E.M.F. to about the value given above. On adding a trace of iodine, 0·0001 per cent., the E.M.F. at once rises to about 1·320 volts, the reading differing slightly for different wires, and on increasing the amount of iodine the E M.F. goes on rising, the readings rapidly approximating until before 0·001 per cent. is reached the readings are all the same. Above this value the E.M.F. rises more slowly, but with regular movements, consequently the E.M.F. becomes a measure of the strength of the solution. The author proposes to use these results for measuring the rate of diffusion of very dilute solutions of iodine, and has made more preliminary experiments with the view of doing this. On diffusing a solution of 0·01 per cent. iodine from a short glass tube, with a platinum wire inserted in the closed end, into a mixture of potassium iodide, and taking readings of E.M.F. every half hour, a very regular curve was obtained showing the gradual diminution of the strength of the iodide solution, and in substituting cadmium for potassium iodide as the solvent, results were obtained so nearly agreeing that apparently the iodine is diffusing independently of the potassium iodide or cadmium iodide molecules. The author is now engaged in trying to measure the actual rate of diffusion and the relation between the rate of diffusion and the temperature of the solution. Incidentally the results show that determinations of the E.M.F. between metals and solutions require in certain cases to be made with considerable care, if the results are to be of any value.

Electrical Communication with Lighthouses.—On the Board of Trade vote, in the House of Commons on Tuesday, for £2,500 for the Mercantile Marine Fund (grant in aid), Sir E. Clarke said the vote was in aid of the expenditure on electrical communication with lighthouses. Nearly three years since the House accepted a resolution in favour of establishing electrical communication with the lighthouses of the country, and a Royal Commission was appointed, which had made two reports upon the matter, and recommended what was looked upon as a limited scheme. The whole sum required had been put at from £200,000 to £300,000. So far only £24,000 had been voted. Mr. A. C. Morton said that he found that the telegrams from lighthouses to the shore as to the locality of wrecks were communicated by the coastguard to the National Lifeboat Association's stations, and were withheld from volunteer lifeboat crews. This was because the first boat to reach the wreck received salvage. He moved to reduce the vote by £1,000. Mr. Bryce said that he was much concerned to hear that anything of the kind had taken place. Clearly every opportunity ought to be given for saving life, and to conceal necessary information would be very wrong. He could only speak for the Board of Trade, and not for the stations which were under the Postmaster-General; but with that limitation he would have enquiries made. As to the point raised by the hon. and learned member for Plymouth, this £2,500 was really a revote of what had been voted in previous years. The works were not begun in time, and the money had to be refunded to the Treasury. The amendment was withdrawn. Sir E. Clarke called attention to an answer given by the right hon. gentleman in June last with regard to the work then completed. Mr. Bryce said that the Gunfleet, the Haisborough light-vessel, and the Tuskar Rock lighthouse had been dealt with, and that three other lights still remained to be done of those to which the money had been devoted. Mr. Hanbury asked what control the Board of Trade would have over the spending of this money. Mr. Bryce said this money was not specially voted or earmarked for the first time. There had been two preceding years in which these special grants had been made. The whole thing had arisen out of the appointment of a commission which recommended that electrical communication should be established in certain cases. The Board of Trade had endeavoured to carry out these recommendations, and in two preceding years Parliament had voted special money for the purpose. It was quite distinct from the Mercantile Marine Fund, the affairs of which were being investigated by a committee presided over by Mr. Courtney. The vote was then agreed to.

Inspection of Electric Light Installations.—Under the auspices of the Chambre Syndicale des Industries Electriques, the Bureau de Contrôle has become an important institution in Paris, exercising, as it does, a kind of paternal government over those private electric light installations the owners of which are members of the bureau. In return for an annual payment the bureau inspects and tests the installations, and for this purpose visits are made and reports on the condition of the installations are drawn up and forwarded to the subscribers. Although under the patronage of the Chambre Syndicale, which nominates the manager and deals with the regulations, the bureau is entirely independent in the carrying out of its work. In order to ensure impartiality in its operations, the manager is forbidden to act as a contractor or manufacturer of electrical appliances, and to possess any interest whatever in any contracting or manufacturing concern. The bureau undertakes, on the ordinary terms, to make two examinations yearly of the installations, these including tests of the insulation and of the meters. In case of any failure the members of the bureau are requested to immediately inform the manager of the bureau, who at once sends an inspector to ascertain the cause and remedy the matter. Tests of the efficiencies of dynamos and

Digitized by Google

accumulators and of measuring instruments are also conducted by the bureau. The annual charges, which are based upon the number of incandescent lamps installed, an arc lamp being considered as five incandescents and each motor or dynamo as 10 lamps, are as follow:

	s.	d.
10 lamps or less, a fixed rate of	4	0
10 to 20, per lamp	0	4¾
20 „ 23, fixed charge.....	8	0
23 „ 50, per lamp	0	4½
50 „ 56, fixed rate.....	18	0
57 „ 100, per lamp	0	4
100 „ 115, fixed charge	32	0
116 „ 200, per lamp	0	3½
200 „ 233, fixed rate	56	0
234 „ 500, per lamp	0	3
500 „ 600, fixed charge	120	0
600 „ 1,000, per lamp.....	0	2½
1,000 „ 1,250, fixed rate	200	0
1,250 upwards, per lamp	0	2

An additional visit to a consumer is charged at the rate of one-third of the annual subscription, with a minimum of 4s. A meter is verified for 16s., and the payment for the labour of an employé is 16s. for half a day and 24s. for a whole day. In cases where the services of the bureau are requisitioned by a non-subscriber, a charge is made at the rate of two-thirds of the annual fee which would have to be paid, according to the number of lamps installed, if the person had been a client.

The Government and Telephony.—The motion mentioned in our last issue for the appointment of a Select Committee to consider the proposed draft agreement between the Postmaster-General and the National Telephone Company, and report with reference to the monopoly which may thereby be created, the granting of telephone licenses to municipalities, and generally on the future policy of the Post Office with reference to the extension of the telephone service, was moved by Mr. Benn in the House of Commons on Friday. In doing so he contended that the agreement could not be regarded as binding, because one of the parties to it, the New Telephone Company, had ceased to exist, having been absorbed by the National Telephone Company, and he submitted that a body which could thus buy out a competitor was at least not entitled to the most delicate treatment. Captain Bagot, who seconded the motion, said that if the present agreement were carried into law, there would be established a gigantic monopoly which would control the whole telephonic system of the country. The Postmaster-General said that the committee which investigated this question reported that the agreement should be submitted to Parliament. But he had spoken to several members of that committee, and they agreed that what was meant was that Parliament should be informed of what had been done. He had not promised that the agreement should be discussed. Any other course than that he proposed to follow would be a repudiation by the Government of the acts of their predecessors, and he could not consent that the agreement should be referred to such a committee. He was not responsible for the terms of that agreement, but he had tried honourably to carry it out. The agreement created no monopoly. The right was reserved by the Postmaster-General to enter into agreements with or grant licenses for telephones to persons, companies, or other bodies. The telephone system was no more local than the post or telegraph service, and to grant municipal licenses would be to treat it as a local and not as an Imperial matter. The Government were, however, prepared to assent to the appointment of a committee to consider the question as to whether the present service was adequate, and whether it might be supplemented by municipal service or otherwise. Sir John Gorst said the policy of the agreement was embodied in the Telegraph Bill, and by passing the Bill Parliament had endorsed that policy. The intention of the late Government was not to create a monopoly, but to prevent the creation of a monopoly. Mr. Goschen, as one largely responsible for the agreement, said the rights of the Government were reserved in the strictest possible way. The power of granting licenses to other companies or to municipalities remained with the Government. The motion as modified to meet the suggestions of the Postmaster-General was agreed to.

Electrical Precipitation from Cyanide Solution. The Siemens and Halske process for the recovery of gold has now been in operation for some months at the Worcester mines of the Rand Central Reduction Company, South Africa. This system was described recently by Mr. A. von Garnet, in a paper read before the Chemical and Metallurgical Society of South Africa. The author, speaking of the working results at Worcester, said there are now in use five leaching vats of 2ft. in diameter with 10ft. staves, each holding 2,700 cubic feet. One tank is discharged and filled each day. The strong solution used contains from ·05 to ·08 per cent. cyanide, and the weak washes ·01 per cent. The actual extraction of fine gold has averaged 70 per cent., while the consumption of cyanide has been ¼lb. per ton of tailings treated. The precipitation plant consists of four boxes 20ft. by 8ft. by 4ft. Copper wires are fixed along the top of the sides of the boxes, and convey the current from the dynamo to the electrodes. The anodes are iron plates 7ft. long, 3ft. wide, and ⅛in. thick. They stand on wooden strips placed on the bottom of the box, and are kept in vertical position by wooden strips fixed to its sides. In order to effect circulation in solutions passing through the box, some of the iron sheets rest right down on the bottom, while others are raised about 1in. above the level of the solution, thus forming a series of compartments similar to those of a zinc-box; the difference being that the solution passes alternately up and down through successive compartments. The sheets are covered with canvas to prevent short-circuit. The lead sheets (cathodes) are stretched between two iron wires, fixed in a light wooden frame, which is then suspended between the iron plates. The boxes are kept locked, being opened once a month for the purpose of the "clean up," which is carried out in the following manner: The frames carrying the lead cathodes are taken out one at a time. The lead is removed and replaced by a fresh sheet, and the frame returned to the box, the whole operation taking but a few minutes for each frame. By this means the ordinary working is not interrupted at all, and the cleaning out of the boxes, which is necessary in the zinc process, is only required at very long intervals. The lead, which contains from 2 to 12 per cent. of gold, is then melted into bars and cupelled. The consumption of lead is 750lb. per month, equal to 1½d. per ton of tailings. The working expenses, including filling and discharging tanks, comes to 3s. per ton. When working on a larger scale the expenses will, of course, be reduced. After the facts mentioned in this paper it will, no doubt, be conceded that electrical precipitation has emerged from its experimental infancy and grown into healthy manhood, and proved itself to be a technical and commercial success, and that it is in every respect at least as good a method of precipitation as the zinc process. Any way, it exists as a tangible fact, which cannot be explained away by argument or ignored by commercial men, who require the best work at the cheapest rate. Sufficient has been said to place the Siemens and Halske process within the category of practical precipitants of gold from cyanide solutions.

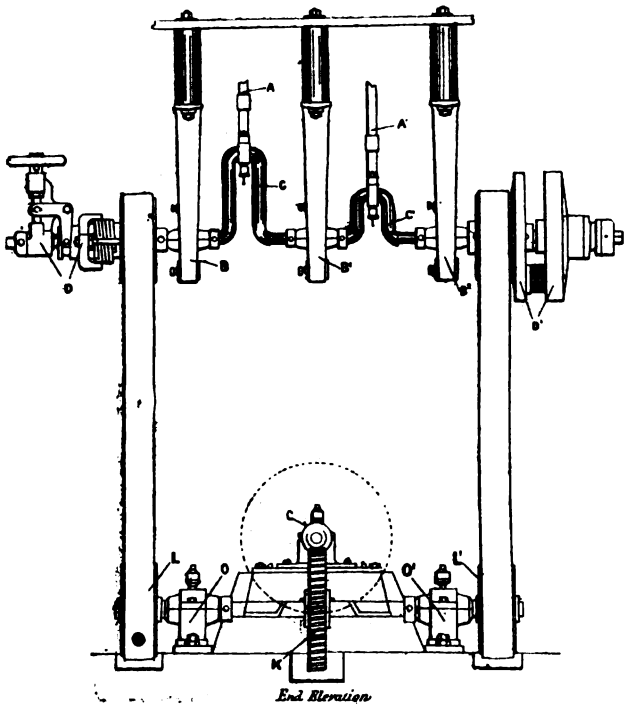
ELECTRIC POWER FOR ORGAN-BLOWING.

In our last issue we gave an abstract of a paper read recently by Mr. Walter J. Fryer, A.I.E.E., on "The Practical Applications of Electricity," before the Institution of Junior Engineers. The author referred, among other matters, to an installation which he had carried out, where electric power is used for the blowing of organ bellows. The motor employed was described in our last issue, and we now give some details of the gearing and clutches, together with an end elevation of the plant.

Referring to the illustration, A, A^1, are the rods connecting the two cranks with the lever of the bellows—A^1 to the heavy pressure, and A to the light pressure; B, B^1, B^2 are hangers with adjustable bearings; C is a 1¼in. crankshaft with 10in. throw; C^1 is a similar crankshaft with a 5in. throw to the crank (these two shafts act quite independently of one another, as they are divided in the centre); D is a clutch pulley made specially for this particular plant by the Coil Clutch Company. It works evenly and well, and consists of a solid cast cone of steel upon which the pulley is keyed. This is loose upon the shaft. A coiled steel spring fits over the cone, and is held by a cast-iron U-shaped clamp on one side and



two L-shaped bolts on the other. The clamp runs horizontally upon a feather, and has a circular groove turned out of it at the end, into which fits a split gunmetal collar attached to a right-angle lever pivoted at the corner and shaped at both ends so as to form forks, one of which grips the gunmetal collar and the other grips the tapped socket, working up and down the screw as the handwheel is turned. The clutch can be so adjusted that the pulley can be caused to run loose at any desired horse-power. The operation is as follows: By turning the small wheel round from left to right the right-angle lever presses against the clamp, moving it to the right, forcing the spring on to the cone, and this gripping the pulley causes the crankshaft C to revolve. The pressure of the spring upon the cone is so adjusted that as the bellows A become full the pulley slips, and the whole of the power can then be utilised for working the opposite crankshaft, C^1. As the bellows become partly empty the spring again grips the cone, and the bellows are once more filled. An eighth of a turn of the small regulating wheel is all that is necessary about once every six months, in order to allow for the wear of the spring and cone. The arrangement works in an automatic manner, without the slightest jerk, and quite noiselessly.

A clutch of entirely different construction, practically consisting of two pieces, is shown at D^1. The half upon which the pulley is cast runs loosely upon the shaft, and is held in position by two collars; projections 3in. long by ½in. in width are cast upon the side of the pulley. The other half is fixed to the shaft by means of a feather, and has 40 bunches of elastic metal teeth 3in. long by 2in. wide attached to it. These teeth engage with the metal projections on the opposite side, and thus cause the shaft C^1 to revolve. The depth of the engagement of the teeth is regulated by means of a brass bush and locking nut. The pulley will then slip when overloaded—that is to say, when the bellows A^1 are full. The spaces between the teeth are filled up with tallow so as to deaden the noise as much as possible; but although this makes a perfect elastic coupling for ordinary use, as it goes into gear without the slightest jerk, it is not so suitable for this purpose as the one previously described. The sizes of both pulleys are 10in. by 4in., and they work at 50 revolutions per minute.

The motor, M, which was described last week, is of 3 b.h.p., capable of working up to 4½ h.p. for short periods; the speed is 2,000 revolutions per minute, and the length of shaft over all, 1ft. 8¼in. The lubrication is carried out by means of loose brass rings dipping into oil. The frequency is 100 cycles per second; the voltage 100; starting current about 68 amperes; current at full load, 41 amperes. The motor is connected on to the worm, G (which is cut out of the solid), by means of a cone coupling. The wheel, K, consists of 40 teeth, thus giving a speed of $\frac{2,000}{40}$ = 50 revolutions per minute to the pulleys, $L L_1$. The wheel is keyed to a 1¾in. shaft supported by two adjustable plummer blocks on sole-plates, $O O^1$, the 10in. by 4in. pulleys being keyed on to the outside of the plummer blocks, and the whole of the gearing is enclosed in an oil bath. The power is then transmitted by means of two double leather orange tan belts, travelling at 135ft. per minute.

INSTITUTION OF CIVIL ENGINEERS.

ELECTRIC TRANSMISSION OF POWER.

Two papers were read on Tuesday before the Institution of Civil Engineers dealing with the electrical transmission of power, Sir Benjamin Baker, K.C.M.G., vice-president, occupying the chair.

The first, on "Electrical Haulage at Earnoch Colliery," by Mr. Robert Robertson, B.Sc., M.I.C.E., opened with an account of the general features of the colliery and of those of its seams into which electric haulage had been introduced. The arrangements of the shafts and the capacities of the cage and coal-hutches were such that the daily output amounted to 1,200 tons. Details were given of the lengths and gradients of the main haulage roads in the Ell and Main coal seams, and of the two steam hauling engines operating those roads on the main and tail and endless-rope systems respectively. Electrical hauling engines had been introduced to drive endless ropes, and to replace horse traction between the main haulage roads and the working faces.

The electrical generating plant comprised a dynamo for supplying power to the electrical hauling engines, capable at a speed of 620 revolutions per minute of an output of 100 amperes at 490 volts. It was driven from a shaft coupled direct to two single-acting Westinghouse engines having cylinders 13½in. in diameter with a length of stroke of 12in. and developing together, when running at their normal speed of 350 revolutions per minute, 122 h.p. with a steam pressure of 50lb. per square inch. The electrical circuits were metallic throughout, and the conductors were highly insulated, being sheathed also in iron pipes in the shaft and supported upon insulators in the workings. The two electrical hauling engines, of which the main features were similar, were next described and illustrated. The motor of the engine in the Ell coal seam, when running at a speed of 770 revolutions per minute, developed 35 h.p. with a current of 76 amperes at a pressure of 400 volts. It was geared, through an intermediate shaft, to two pulleys with Hurd clips, each provided with a friction clutch and brake, by which the cables were driven at a speed of three miles per hour. The two cables were of stranded steel wire ¾in. in diameter, and, after passing over balance-wheels placed

Digitized by Google

in recesses near the engines, operated circuits of 2,160 yards and 1,020 yards in length respectively. The cables were supported at intervals of about 30ft. along the roads by rollers 4½in. in diameter, and at the corners were passed over wheels 5ft. in diameter, mounted upon vertical axes below the level of the rails. The gradients were so arranged at the corners that the trains of trucks could there travel without aid from the ropes. In the Main coal seam a cable operated similarly a circuit 1,580 yards in length. The cables were driven continuously at a uniform speed, and the coal-hutches were attached to or detached from them by a Smallman clip.

The efficiency of the plant as compared with the horse traction, which it had replaced, was then considered. The electrical haulage system in the Ell coal seam was capable of a daily output of 400 tons. The daily output by horse traction had been 180 tons, and to increase this to 400 tons 30 or 40 horses would have been required, a number which could not have been employed in the available space without confusion. The daily output of the electrical haulage system in the Main coal seam, which was not yet working at its full capacity, was between 150 and 200 tons. The yearly working expenses of the two systems were compared upon the results of one and a half year's working, and were found to be £4,130 and £1,990 by horse traction and by electrical haulage respectively, showing that an annual saving of £2,140 had been effected by the latter. The total cost of the electrical installation had been £3,500.

In the second paper, "Water Power applied by Electricity to Gold Dredging," by Mr. Robert Hay, M.I.C.E., an account was given of plant which had been erected in New Zealand to utilise water power for generating electricity to be transmitted to motors operating a dredge in different portions of a distant river. The author pointed out that the transmission of water power by electricity in well-watered countries like New Zealand, rendered available deposits of gold in districts in which the scarcity of fuel would not permit of their being worked by other means. The plant described had been constructed for gold dredging in the River Shotover, the course of which was for the most part in rocky gorges through rugged country, accessible only by tracks cut down the leading spurs and gullies. The source of the water power and the method of its application were then described, and illustrated by a longitudinal section of the pipe line. The water was obtained at a creek one and a half miles distant from the dredging ground, and was brought by a race cut in the side of the hill, or in places where the ground was not suitable in a timber flume, to a pressure tank at a level of 524ft. above the pipes at the generator-house. From this tank to the Pelton wheel the water was carried in rolled-steel pipes constructed in lengths of 19ft. 6in., bolted together by wrought-iron flanges riveted to the pipes.

The prime mover of the generating plant was a 4ft. Pelton reaction waterwheel, upon the buckets of which the water from a nozzle 1½in. in diameter impinged at a pressure of 228lb. per square inch. This wheel drove two series-wound dynamos working at a normal speed of 700 revolutions per minute, each developing a current of 40 amperes at an E.M.F. of 650 volts, or together nearly 70 h.p. The dynamos were coupled in series, and to guard against damage from abnormal increase of current, a regulator was so arranged as to throw into the circuit an artificial load, in case of the current becoming from any cause three amperes greater or less than its normal amount. The conductors, of a length of two miles, were of No. 4 S.W.G. bare copper wire, and were supported upon insulators carried by cross-arms upon old 40lb. rails. The current was conducted to two motors in the dredge—one for driving a centrifugal pump, and the other for operating the buckets, winches, and revolving cylinder. These two machines were duplicates of the dynamos, and were coupled in series so that when the bucket motor was switched off, the pump motor absorbed the surplus power by increasing the speed of the pump and causing it to throw more water. The dredge was constructed for the most part of steel, and was capable, when operating at a depth of 20ft., of an output of 90 cubic yards per hour. The dredgings were delivered through a revolving screen for separating the stones and coarser material, upon baize tables set at an inclination of 1 in 12. Two 10-ampere arc lamps lighted the dredge at night, and were joined in multiple series with the motors, with suitable arrangements for their control. A table of particulars of the efficiencies of various parts of the plant was given. The cost of the installation and the weekly working expenses, £7,000 and £35 respectively, were also tabulated.

STEAM TRAMWAYS IN ITALY.

BY P. AMORETTI.

In a previous issue we referred to the paper contributed to the *Proceedings* of the Institution of Civil Engineers on this subject by Mr. P. Amoretti, manager of the Steam Tramway Association of Turin. We now give an abstract of the paper.

At the end of the year 1890, the length of steam tramways constructed in Italy was stated in the official returns as 1,575 miles, and about 300 miles have been constructed since that time. Owing partly to the commercial crisis through which Italy has recently been passing, and partly to the unsatisfactory results of the working of many of the lines, the rate of construction has much diminished since the close of 1890.

The existing network originated in the lines radiating from large centres, such as Turin and Milan; lines, originally terminating in the immediate suburbs, being extended to outlying points, until they met or crossed lines from other centres. At first these various lines were worked independently of each other, and their functions were limited to local traffic, but as the system extended joint working arrangements were made, and through traffic was provided for between the several lines and, where practicable, over the railway systems. This development was, of course, impossible where varying gauges had been adopted. About 36 tramway companies, working 1,365 miles, have since 1886 combined to form the Italian Tramway Association, by which a common basis of working is established and all administrative matters discussed and regulated.

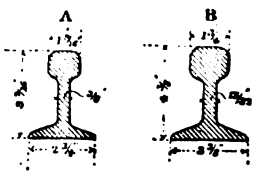


FIG. 1.

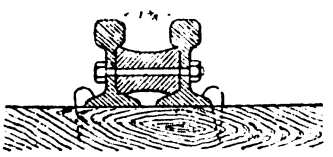

FIG. 2.

In the majority of cases the standard Italian railway gauge, 4ft. 8½in., has been adopted. The steel rails used are exclusively of the Vignoles type, fixed direct to the sleepers on straight lengths and on chairs when in curve. In towns guard rails are used to facilitate packing the metalling, the width for the flange of wheel being about 1⅜in. The rail generally adopted (Fig. 1 Type A) weighs 36lb. per lineal yard; but where the engines used weigh over 12 tons, or the traffic is very heavy, the section Type B, weighing 42lb. per lineal yard, is used. The sleepers are always of oak, which abounds in Italy, the dimensions for standard gauge lines averaging 4¼in. by 7in. by 7ft. 3in. long. The rails are secured to the sleepers with spikes, the use of coachscrews having shown very unfavourable results. Guard rails, Fig. 2, are used in nearly all cases of curves of less than 2½ chains (55 yards) radius. The points vary little from those on railways.

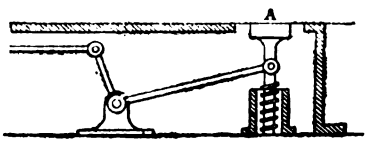

FIG. 3.

They are generally worked by levers with counterweights; but in towns where such an arrangement could not be adopted in the open street, the lever is contained in a cast-iron box flush with the ground level, Fig. 3, and is

Digitized by Google

fitted with a foot-plate and counter-spring. The plate is thus kept in its normal position, flush with the opening at the ground level; but when pressed downwards by the foot, it operates the lever and moves the points.

In regard to curves and gradients, the one general guiding principle that has been followed appears to be simply to construct the line at all hazards. The articles of concession usually state that no curves shall have a radius less than 55 yards; but the exceptions granted have been so numerous that it may be said that no practical limit is recognised. It is the same with the gradients as with the

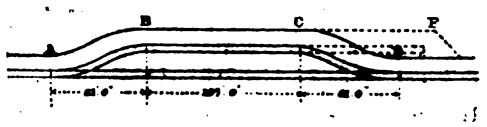

Fig. 4.

curves; in any case the limiting rate of inclination can, in view of the system of simple adhesive traction, only be considered as excessive. With but few exceptions—these being trunk routes, common to several lines—the steam tramways of Italy are all single lines, with passing places at such distances as are required by the extent of the traffic. These passing places, Fig. 4, are usually placed on the side away from the road, if an extra strip of land can be acquired for the purpose. Where shunting is of ordinary occurrence, or cars have to be left

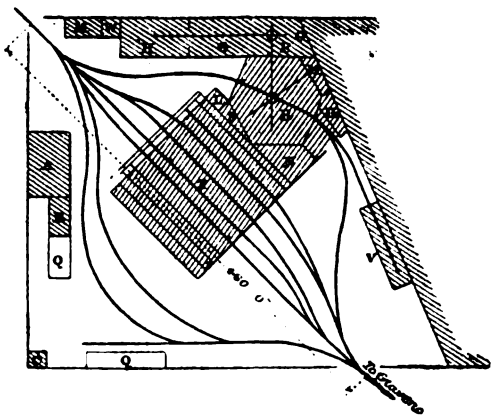

Fig. 5.

for loading or unloading, it is desirable to construct a short dead-end siding. So far as possible, these passing places are provided on public ground or at regular stations, as the tramway companies have no compulsory powers for the purchase of land.

The Turin station of the Turin, Orbassano, and Giaveno line is shown in Fig. 5. It is technically a terminal station,

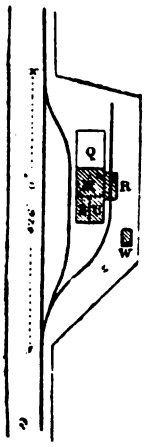

Fig. 6.

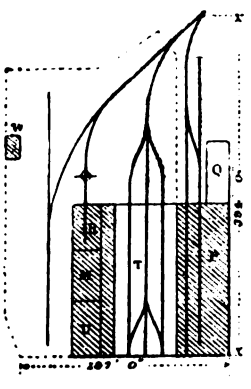

Fig. 7.

though the starting point is nearly 1,000 yards further towards the centre of the city, where it was impracticable to acquire the necessary ground. The letters on the plan indicate: A, booking-office; B, goods warehouse; Q, goods-sheds; T, carriage-shed; R, engine-shed; and M, V, F, G, and H, repairing-shops, forge, and stores. Fig. 6 is an example of a small wayside goods station at Piossasco. The passenger building (booking-office and waiting-room) is shown by S, U; M, Q, and R being respectively warehouse, goods-shed, and carriage lock-up. The terminal station of Giaveno, where there is in a small space a considerable traffic of both passengers and goods, is shown in Fig. 7. The references are: U, booking-office and waiting-room; R, engine-shed; T, roof over arrival and departure lines, forming carriage-shed; P, goods warehouse; and Q, open goods-shed.

If regular stations are of infrequent occurrence on the steam tram lines, the connections with private sidings are, on the other hand, very numerous. By the fact of their construction on the high roads the lines afford direct communication with farms, fruit gardens, dairies, mills, factories, ironworks, brickworks, limekilns, quarries, and mines in a manner unattainable on such a general scale by ordinary railways. The trucks are loaded direct, and run without any transfer straight to their point of distribution, while the materials required from the city by the works and factories are similarly brought to them with a minimum of expense in handling. The development of this important branch of traffic resources has induced the various companies to do their utmost to facilitate loading and unloading processes. The rolling-stock of the different companies varies greatly in its proportion to mileage. At

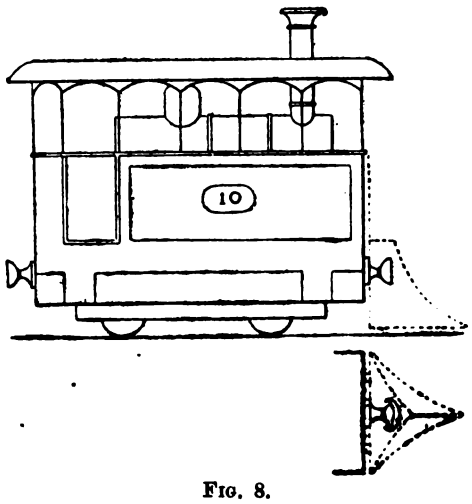

Fig. 8.

the nearest approximation to an average the number of engines is from 0·12 to 0·19 per mile of line worked, passenger cars from 0·3 to 0·6, and freight trucks from 0·3 to 0·9. The general appearance of the engine with its casing is shown in Fig. 8. The screen or casing hangs to within 4in. of the rail level. The total weight of the machine in full working order varies from eight to sixteen tons, the exceptional maximum being 20 tons. The diameters of the cylinders vary from 7in. to 11in., the usual type in 12 to 14 ton engines having a diameter of 9½in. The average distance of the axles from centre to centre is 5ft. 3in., with wheels 1ft. 11in. or 2ft. 2¼in. diameter. Neither condensers nor smoke consumers are adopted. Welsh coal is usually burnt, and wire spark-guards are fitted on the chimney. During the winter the plains in the valley of the Po, and to an even greater extent the lateral valleys, are frequently covered with a considerable

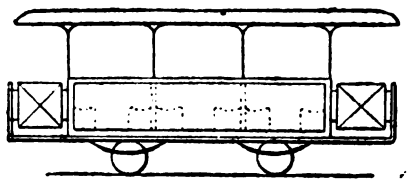

Fig. 9.

depth of snow; and to clear this, when the depth does not exceed 18in., a small snow-plough, shown by the dotted line, is fitted on the engine.

Passengers are conveyed in carriages (Fig. 9) providing 16 seats and 16 standing places, first class; or 24 seats and 16 standing places, second class; or a mixed type providing

Digitized by Google

eight seats and eight standing places, first class, and 12 seats and eight standing places, second class. In a few cases longer carriages on two bogie frames have been tried, but, as a rule, the smaller carriages are preferred, as the train is made up more easily to suit the requirements of the moment. There is no general provision of separate luggage vans, but one compartment is usually reserved for the carriage of passengers' luggage. The ordinary carriages—*i.e.*, standard gauge—weigh on an average from 3 tons to 3½ tons, and the open cars 2 tons to 2½ tons, showing a great advantage in favour of the latter during the season when they can be worked. Goods trucks generally resemble those used on the railways, their capacity ranging from 6 tons to 8 tons, and their weight (empty) varying from 2½ tons to 3½ tons for open trucks, and from 3½ tons to 4½ tons for covered vans.

All the passenger cars and nearly all the freight cars on the steam tramways are provided with brakes, so that each conductor has one close at hand. Those usually employed are chain-brakes on the passenger cars and screw-brakes on the trucks. Continuous brakes are only adopted in a few instances. On some lines, where the companies are trying to get permission from the Government to run their trains at a speed exceeding the regulation 24 kilometres an hour, the proposal has been made to adopt continuous brakes; and this arrangement, now under consideration, will most likely be accepted by the Government.

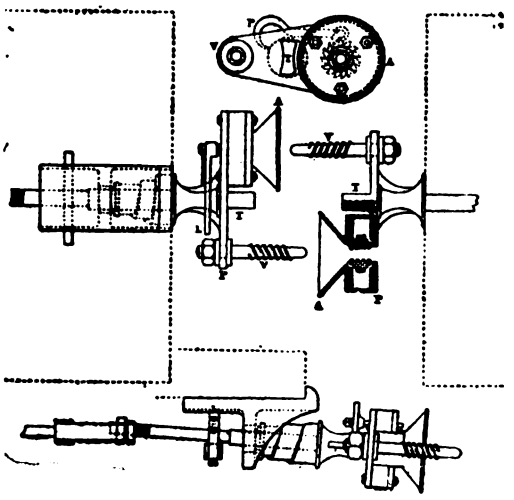

Fig. 10.

The vehicles are usually connected by a central coupling, but of late the Prada coupling (so named after its inventor) has been extensively used. This coupling is automatic in its action—that is to say, two vehicles coming into contact become at once coupled. Upon a plate, P (Fig. 10), is mounted at one end a double-threaded screw, V, and at the other end a conical guide cup, A, terminating in a collar in which is fitted a screw union revolving in one direction only while the levers, L, are in their normal position. With two cars similarly fitted, the screw, V, and the guide and union, A, of the one are respectively opposite the guide and union, A, and the screw, V, of the other. The screws, V, on coming into contact with the unions, are gripped home, and the connection remains perfect until the levers, L, are raised, when the unions are free to revolve in the opposite direction, and so to release the coupling screws. The system has now been working satisfactorily for several years. On the Italian steam tramways, it must not be forgotten that at least one telegraphic connection is compulsory between all stations and stopping places along the line. This regulation was enforced recently by the Government.

The original Government regulations for the trains to be run on public roads were:

Maximum weight of train, including engine	30 tons.
,, length ,, ,, ,, ...	100 feet.

An alternative regulation allowed four vehicles (each of about 20ft. length), and the engine about 17ft. These limits have since been extended, and for trains running at from 10 to 12 miles an hour six vehicles, in addition to the engines, are now allowed, while still greater latitude is given if the speed is reduced.

The nearest possible approximation seems to be from £1,280 to £1,920 per mile for cost of construction, of which amount about £960 is required for the permanent way, materials, and laying. The cost of land or of station buildings is, of course, not included in the above statement; it frequently works out at from £320 to £380 per mile, but it is practically impossible to arrive at any general average. In regard to rolling-stock, the cost of equipment varies from £450 to £570 per mile. Sundry items of supervision, compensation, workshops, telegraph or telephone, furniture, etc., come to from £100 to £200 per mile. The average total, therefore, as nearly as can be stated, is £2,600 per mile.

Leaving out of consideration some exceptional cases, both of bad and of good receipts, the average gross earnings are about £400 per annum per mile of line worked. The average of working expenses cannot be less than £125 per mile over flat country, or £160 per mile on hilly ground. The average of returns which the author has been able to analyse give, in round figures, £300 per mile—*i.e.*, 75 per cent. of the average gross receipts. The net earnings are therefore about £100 per mile, and the average dividends — *i.e.*, on ordinary shares — are about 3 per cent.

PRACTICAL NOTES ON DYNAMO CALCULATION.*

BY ALFRED E. WIENER.

(Continued from page 250).

The combination of two horseshoes with common pole-pieces furnishes two further forms of field-magnet frames. Fig. 81 shows the horizontal double-horseshoe type, and Fig. 82 the vertical double-horseshoe type.

Machines of the former type, Fig. 81, are built by the United States Electrical Company (Weston), New York; the Brush Electrical Company, Cleveland, O.; the Ford-Washburn Storelectric Company, Cleveland, O.; the Western Electric Company, Chicago, Ill.; the Fontaine Crossing and Electric Company ("Fuller"), Detroit, Mich.; by Crompton and Co., London, England; by Laurence, Paris, and Scott, England; and by Schuckert and Co., Nuremberg, Germany.

The latter form, Fig. 82, is employed in dynamos of Fort Wayne Electric Corporation ("Wood"), Fort Wayne, Ind.; La Roche Electric Works, Philadelphia; Granite State Electric Company, Concord, N.H.; Electric Construction Corporation (Elwell-Parker); and Crompton Company, London, England.

If one or both the pole-pieces of a consequent-pole double-magnet type are prolonged in the axial direction—that is, toward the armature—and the winding is transferred from the cores to these elongated pole-pieces, then a type is obtained in which the magnet frame forms a closed iron wrappage with inwardly protruding poles. Forms of this feature are known as iron-clad types, and according to the number of magnets and to their position are single-magnet and double-magnet, horizontal and vertical iron-clad types.

Fig. 83 shows the horizontal iron-clad type, having two horizontal magnets. It is used by the General Electric Company ("Thomson-Houston arc light type"), Detroit Electric Works, Detroit, Mich.; Eickemeyer Company, Yonkers, N.Y.; Fein and Co., Stuttgart; and Aachen Electrical Works (Lahmeyer), Aachen, Germany.

A modification of this type consists in letting the poles project parallel to the shaft, one above and one below, or one on each side of the armature; the only magnetising coil required in this case will completely surround the armature. This special horizontal iron-clad form, which is illustrated in Fig. 84, is realised in the Lundell machine, built by the Interior Conduit and Insulation Company, New York.

In Figs. 85 and 86 the two possible cases of the vertical single-magnet iron-clad type are depicted, the magnet being placed above the armature in the former and below the armature in the latter case. The single-magnet iron-clad

* From the *Electrical World* (New York).

Digitized by Google

overtype, Fig. 85, is adopted in the machines of the Muncie Electrical Works, Muncie, Ind., and in the battery fan motor of the Edison Manufacturing Company, New York. Machines of the single-magnet iron-clad undertype, Fig. 86, are built by the Brush Electrical Engineering Company ("Mordey"), London, and by Stafford and Eaves, England.

The vertical double-magnet iron-clad type, Fig. 87, having two vertically projecting magnets, one above and one below the armature, is employed in machines of the Wenstrom Electricity Company, Baltimore; the Triumph Electric Company, Cincinnati, O.; the Shawhan-Thresher Electric Company, Dayton, O.; the Card Motor Company, Cincinnati, O.; the Johnson Electric Service Company, Milwaukee, Wis.; the Erie Machinery Supply Company, Erie, Pa.; and the Zurich Telephone Company, Zurich, Switzerland.

There are various other bipolar types, which, however, mostly are out of date, and therefore of very little practical importance. These can easily be regarded as special cases of the types enumerated above.

(b) Multipolar Types.—Multipolar field-magnet frames can have one or two magnets for every pole, or each magnet can independently supply two poles, or one single magnet, or two magnets may be provided with pole pieces of such shape as to form the desired number of poles of opposite polarity.

If the number of magnets is identical with the number of poles, the magnets may either be placed in a radial, a tangential, or an axial position with reference to the armature, and in the two first-named cases they may be put either outside or inside of the armature.

The radial outer-pole type is shown in Fig. 88; this form has been adopted as the standard type for large dynamos of the General Electric Company, Schenectady, N.Y.; of the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa.; the Crocker-Wheeler Electric Company, Ampere, N.J.; the Riker Electric Motor Company, Brooklyn; the Stanley Electric Manufacturing Company, Pittsfield, Mass.; the Fort Wayne Electric Company, Fort Wayne, Ind.; the Eddy Electric Manufacturing Company, Windsor, Conn.; the Belknap Motor Company, Portland, Me.; the Shawhan and Thresher Electric Company, Dayton, O.; the Great Western Electric Company (Bain), Chicago; the Walker Manufacturing Company, Cleveland, O.; the Mather Electric Company, Manchester, Conn.; the Claus Electric Company, New York; the Commercial Electrical Company, Indianapolis; the Allgemeine Electric Company (Dobrowolsky), Berlin, Germany; the Oerlikon Machine Works, Zurich, Switzerland; Alioth and Co., Basle, Switzerland; the Berlin Electric Construction Company (Schwartzkopf), Berlin, Germany, and numerous others.

In Fig. 89 is represented the radial inner-pole type, which is used by the Siemens and Halske Electric Company, Chicago, Ill., and Berlin, Germany; by the Alsacian Electric Construction Company, Belfort, Alsace; by Naglo Bros., Berlin, Germany; by Fein and Co., Stuttgart, Germany; and by Ganz and Co., Budapest, Austria.

The tangential outer-pole type, Fig. 90, is employed by the Riker Electric Motor Company, Brooklyn; by the Baxter Motor Company, Baltimore, Md.; the Mather Electric Company, Manchester, Conn.; the Dahl Electric Motor Company, New York; the Electrochemical and Speciality Company, New York ("Atlantic" Fan Motor); and by Cuenod, Sautter, and Co. (Thury), Geneva, Switzerland; generators of this type are further used in the power station of the General Electric Company, Schenectady, N.Y.; and in the Herstal, Belgium, Arsenal.

Machines of the tangential inner-pole type, Fig. 91, are built by the Helios Electric Company, Cologne, Germany.

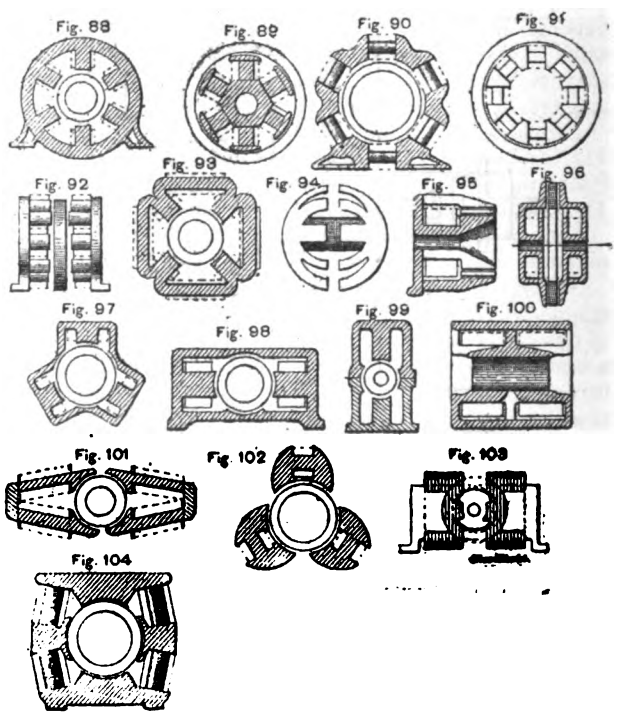
In the axial multipolar type, Fig 92, there are usually two magnets for each pole, one on each side of the armature, in order to produce a symmetrical magnetic field. This form is used by the Short Electric Railway Company, Cleveland, O.; Schuckert and Co., Nuremberg, Germany; Fritsche and Pischon, Berlin, Germany; Brush Electric Engineering Company, London, England ("Victoria" dynamo); and by M. E. Desroziers, Paris, France.

Fig. 93 shows the raditangent multipolar type, which is a combination of the radial and tangential outer-pole types, Figs. 88 and 90 respectively, and which is employed by the Standard Electric Company, Chicago, Ill.

If only one magnet is used in multipolar fields, the pole-pieces may be so shaped as to face the armature in an axial or in a radial direction. In the former case the axial-pole single-magnet multipolar type, Fig. 94, is obtained, which is used by the Brush Electrical Engineering Company (Mordey), London, England; and by the Fort Wayne Electric Company (Wood), Fort Wayne, Ind.

In the latter case the outer-inner pole single-magnet type, Fig. 95, results, in which the pole-pieces may either all be opposite the outer or the inner armature surface, or alternately outside and inside of the armature; the latter arrangement, which is the most usual, is illustrated in Fig. 95, and is employed by the Waddell-Entz Company, Bridgeport, Conn., and by the Esslingen Works, Wurtemberg, Germany.

If two magnets furnish the magnetic flux they are placed concentric to the armature and the two sets of pole-pieces so arranged that adjacent poles on either side of the armature are of unlike polarity, but that poles facing each other on opposite sides of the armature have the same polarity. Such a double-magnet multipolar type is shown in Fig. 96; it is that designed by Lundell, and built by the Interior Conduit and Insulation Company, New York.



In giving the yoke of the radial multipolar type, Fig. 88, such a shape as to form a pole-piece between each two consecutive magnets an iron-clad form is obtained, having alternate valient and consequent poles, and requiring but one-half the number of magnets as a radial multipolar machine of same number of poles.

Fig. 97 shows a field frame of the multipolar iron-clad type, having six poles, which is the form employed in the gearless street car motor of the Short Electric Railway Company, Cleveland, O. In Figs. 98 and 99 two special cases of this type are depicted, both representing four-polar iron-clad types, and differing only in the position of the magnets. The horizontal four-polar iron-clad type, Fig. 98, is used in the Edison iron-clad motor (General Electric Company) and in the dynamos of the Wenstrom Electric Company, Baltimore, Md. The vertical four-polar iron-clad type, Fig. 99, is employed by the Elliott-Lincoln Electric Company, Cleveland, O.

Fig. 100 shows a special case of the horizontal four-polar iron-clad type, obtained by symmetrically doubling the frame illustrated in Fig. 84, and providing four poles instead of two. The cores are so wound that the centre of the cylindrical iron wrappage has one polarity and the ends the opposite polarity. Two oppositely situated pole-pieces

Digitized by Google

are joined to the middle, and the two sets of intermediate ones to the ends of the magnet frame; the lower half of Fig. 100 consequently is a section taken at right angles to the upper half, the diametrically opposite sections being identical. This type has been developed by the Storey Motor and Tool Company, New York.

Multipolar fields may also be formed by a number of independent horseshoes arranged symmetrically around the outer armature periphery. Figs. 101 and 102 show two such multiple-horseshoe types, double-magnet horseshoes being employed in the former and single-magnet horseshoes in the latter type. Multiple-horseshoe machines of the double-magnet form, Fig. 101, have been designed by Elphinstone and Vincent, and by Elwell-Parker Electric Construction Corporation, England, while the single-magnet form, Fig. 102, is employed by the Electron Manufacturing Company (Perret), Springfield, Mass.

Further forms of multipolar fields can be derived from the bipolar horizontal and vertical double-magnet types respectively. If in the vertical double-magnet type, Fig. 76, an additional pole-piece is provided at the centre of the frame so as to face the internal surface of the armature at right angles to the outer pole-pieces, the four-polar vertical double-magnet type is created, which when laid on its side will constitute the four-polar horizontal double-magnet type, Fig. 103. If in the vertical double-magnet type, Fig. 78, the two cores are cut in halves and additional pole-pieces inserted at right angles to the existing ones, the vertical quadruple-magnet type, Fig. 104, is obtained; the same operation performed with the horizontal double-magnet type (77) will give the horizontal quadruple-magnet type.

Four-polar horizontal double-magnet dynamos are, Fig. 103, built by the Zurich Telephone Company, Zurich, Switzerland; and vertical quadruple-magnet machine, Fig. 101, by the Duplex Electric Company, Corry, Pa.

Numerous other multipolar types have been invented and patented, but have not yet come into practical use.

Selection of Type.—If the type is not specified, the field-magnet frame for a large-output machine should be chosen of one of the multipolar types, as in these the advantage of a better proportioning and a higher efficiency of the armature winding, and the possibility of a symmetrical arrangement of the magnetic frame, results in a saving of copper as well as of iron; while for smaller machines—below 10 kilowatts capacity—the bipolar forms are preferable on account of the great complication caused by the increased number of armature sections, commutator divisions, field coils, etc., necessary in multipolar machines, and on account of the narrowness of the neutral or non-sparking space on a multipolar commutator.

The field, moreover, should have as few separate magnetic circuits as possible; thus in the case of a bipolar type, it should be a single magnetic circuit rather than the consequent-pole type which is formed by two or more magnetic circuits, of one or two magnets each, in parallel, because the former is more economical in wire and in current required for excitation. In two-circuit consequent-pole machines, for instance, such as the double-magnet types, Figs. 77, 79, and 80, and the double-horseshoe types, Figs. 81 and 82, according to Table LIII., Chapter 43, there is 1·41 times the length of wire, and consequently also 1·41 times the energy of magnetisation, required than in a single circuit, round cores being used in both case, and the single circuit having exactly twice the area as each of the two parallel circuits in the consequent-pole machines. Triple and quadruple magnetic-circuits—*i.e.*, three or four cores, or sets of cores, magnetically in parallel—are still more objectionable, requiring, when the cores are of circular cross-section, 1·73 and 2·00 times as much wire respectively as a single magnetic circuit having a round core of equal total sectional area.

If a machine has several magnetic circuits, each of which, however, passes through all the magnets in series, then the frame is to be considered as consisting of but one single circuit, for the subdivision only takes place in the yokes, and it is immaterial as to the length of exciting wire whether the return path of a single circuit is formed by one yoke or by a number of yokes magnetically in parallel. The above-named objection to divided-circuit types consequently does not apply in the case of the iron-clad forms, Figs. 83 to 87.

According to Table LII., Chapter 40, the horizontal double-magnet type, Fig. 75, and the horizontal iron-clad type, Fig. 83, are the best bipolar forms, magnetically. The iron-clad types, furthermore, possess the mechanical advantage of having the field windings and the armature protected from external injuries by the frame of the machines, which makes them eminently adaptable to motors for railway, mining, and similar work.

The inverted horseshoe type, Fig. 68, which ranks very highly as far as its magnetic qualities are concerned, has the centre of its armature at a comparatively very great distance from the base, requiring very high pillow-blocks, which have to carry the weight as well as the downward thrust of the armature inherent to the inverted forms having the field windings below the centre of revolution (see Chapter 24). The side pull of the belt with a high centre line of shaft tends to tip the machine, and the changes in the pull due even to the undulations of the belt will cause a tremor in the frame, which jars the brushes and eventually loosens their holders, and which has a disastrous influence upon the wearing of the commutator. On this account the inverted forms, or "under-types," can only be used for small and medium sized machines, in which the height of the pillow-blocks remains within practical limits.

In selecting a multipolar type, Table LII. shows that the radial inner-pole type, Fig. 89, offers the best advantage with regard to the magnetical disposition; with this type, however, are connected some mechanical difficulties, due to the necessity of supporting the frame from one of its ends, laterally, and the armature from the other.

In the outer-pole types the armature core can be supported centrally from the inner circumference, and the frame suitably provided with external lugs or flanges resting upon the foundation, a most desirable arrangement for mechanical strength and convenience. The most favourite of the outer-pole forms is the radial outer-pole type, Fig. 88, on account of its superiority, magnetically, over the tangential and axial multipolar types.

In all dynamo designs the consideration is especially to be borne in mind that the whole machine, as well as its various parts, should be easily accessible for inspection, and so arranged that they can conveniently be removed for repair or exchange. A large number of machines owe their popularity chiefly to their good disposition in this respect.

The shape of the frame in all cases is preferably to be so chosen that the length of the magnetic circuit in the same is as short as possible.

(To be continued.)

LEEDS TRAMWAYS.

In the report presented to the Tramways Committee of the Leeds City Council, the city engineer (Mr. Hewson) states that he is in favour of a quicker service of cars than obtains at present. He thinks it should not be less than one of 7½ minutes, with short routes across the city, and consequent overlappings of 3¾ and 1⅞ minutes' service in the centre. On this basis, Mr. Hewson makes a comparison of cost between the present system of haulage, the cable, and the electric system. He takes first the capital, and secondly the annual sum each would require, remarking, however, that his estimates do not include the use of the spare heat at the refuse destructors, his reason for this being that, even supposing the whole cost of fuel could be saved by utilising this heat, the saving would be less than the gain from having the overhead electric generating system at one central station, or the cable system at a minimum number of stations, all being placed in the best situation for coal, water, and economical working. With respect to the present system, he finds that the total first cost, and the cost of remodelling the existing tramways, including buildings and improved equipment up to 7½ minutes' service, would be £265,884. As to the cable, his estimate

Digitized by Google

is £428,922. For the overhead electric system, the estimate is £378,499.

With regard to the annual cost of working these three systems, the figures are based on the service suggested—viz., 7½ minutes in the outskirts and 3¾ and 1⅞ minutes in the centre of the city. The total annual cost of the present system he puts down at £117,292; of the cable at £101,819; and of the overhead electric system at £90,072. Thus we have:

	Estimated capital account.	Estimated annual cost.
Present system	£265,884	£117,292
Electric system	378,499	90,072
Cable system	428,922	101,819

The difference in favour of the overhead electric system over the cable system is therefore £50,423 in capital account and £11,747 in annual cost. As the number of cars and service in each of the systems would be alike, the income on each of the systems would be exactly the same.

In conclusion, Mr. Hewson remarks that whilst it is true that the cable cars with a certain frequency of service beat the electric overhead in point of cost, excepting in towns having more severe gradients and a longer length of them than there are in Leeds, this feature has been greatly exaggerated. He finds that the frequency required must be less than a 1⅞ minutes' service; but it should be remembered (to be complete in this respect) that that service must extend over the whole tramway system, or the cable system of the city fails. Such a service is out of the question. For instance, supposing Briggate and North-street, Boar-lane, Wellington-street, and Woodhouse-lane to Hyde Park-corner were on such a service as would give the advantage to the cable—say a one-minute service—the cable system for the whole undertaking of Leeds would then have only 6½ miles of paying line to meet the loss of 28½ miles in the remaining—*i.e.*, the slower part of the system. It has been suggested to Mr. Hewson—and until going into figures he thought such an arrangement might be feasible—that the centre of the city should be worked by cable system and the outskirts by electricity, but from the figures he has already given it will be seen that the cable system with its necessarily quick service and the traffic needful to warrant such a service would be so limited in length as to render such a suggestion not practicable. Comparing the advantages of the two systems, even ignoring finance, it appears, putting it broadly, that if it were not for the objectionable appearance which the poles and wires of the electric overhead system lends to the streets and the weight of the car, that system would be practically in all respects superior to the cable. In regard to the weight of the car, it is only 6¼ tons, and not 9½ tons, as is generally stated, and the weight of those now being made is only five tons, whilst the weight of the present bogie cars drawn by steam-engines is 4½ tons, thus leaving little to be complained of in this respect. As to the poles and wires, a great improvement can be made in regard to them also. All the wires running along the footpath should be laid underground, and all the poles placed against the buildings, or when the width of the streets will permit, ornamental posts carrying arc lights should be placed in their stead in the centre of the roadway. With these improvements, and remembering that electric traction has a wider field for improvement than cable, he is of opinion that the overhead electric system of haulage is certainly the cheapest and the best system for the city of Leeds.

THE RECENT GAS EXPLOSIONS IN ST. PANCRAS.

ANOTHER EXPLANATION OF THE CAUSE.

The following is a copy of a letter addressed by Sir Courtenay Boyle, on the 28th ult., to the chairman of the Electric Lighting Committee of St. Pancras Vestry:

Adverting to the interview which you were good enough to give me yesterday, and to the conversation which we had on the subject, I am directed by the Board of Trade to state, for the information of the Electric Lighting Committee of the St. Pancras Vestry, that Major Cardew, the electrical adviser of this department, has discovered in his investigations into the recent explosions in the street boxes used for electrical supply in St. Pancras, that a remarkable deposit on some of the insulators contained a considerable quantity of the metal sodium.

The presence of this metal, which is highly inflammable by contact with water, appears to be so grave a source of danger, and to afford so reasonable an explanation, in connection with the accumulation of escaped coal gas, of the several explosions which have recently occurred, that it devolves upon the Board of Trade without any delay whatever to investigate the causes of the deposit of this substance with a view to its prevention, and in this investigation they have asked for the assistance of the Royal Society and of the Institution of Electrical Engineers.

In the meantime, in order to prevent as far as possible the recurrence of similar explosions, the Board of Trade would strongly urge that the Vestry, through their Electrical Committee, should immediately—

(1) Provide a thorough system of ventilation for their conduits and street boxes.

(2) Reduce as far as possible the space in their street boxes within which an accumulation of gas can occur.

(3) Make a thorough inspection of their mains and remove the above-mentioned deposit wherever it is found to exist.

As regards the means to be taken for prevention of the recurrence of such deposit, the Board of Trade hope to be able to communicate with you further without delay.

Mr. A. E. Pycraft, of the Electricity and Public Lighting Department of the St. Pancras Vestry, sent the following reply to Sir Courtenay Boyle on the 1st inst.:

A special meeting of the Electricity Committee was held last evening, when the chairman reported the conference held at your offices on Wednesday last on the subject of the recent explosions, and your letter of the 28th ult. was considered. I was instructed to inform you that the committee desire to record appreciation of the courtesy shown by you in the desire to assist the Vestry, and are thoroughly in accord with the Board of Trade in their desire to prevent a recurrence of the explosions that have recently taken place.

With regard to the several recommendations contained in your letter, the committee have instructed their engineer to have fixed without delay ventilating pipes for getting rid of any accumulation of gas in the manholes and culverts, and pending further consideration respecting reducing the size of the manholes to fill them up as far as practicable with bricks. Extra men have also been engaged inspecting the mains and removing whatever deposit may be found on them. The committee note the Board of Trade have asked the Royal Society and Institution of Electrical Engineers to investigate into the causes of the deposit of the metal sodium, and that the Board will inform the Vestry the result of such investigation.

The committee also expressed a hope that the Board of Trade would bring pressure to bear on the gas company to remedy the defective state of gas mains and services in this district, and thus remove the primary cause of the explosions.

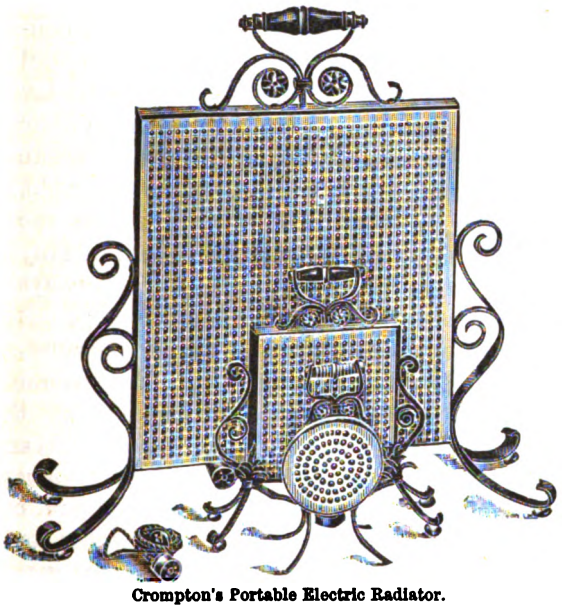
ELECTRIC HEATING OF THEATRES.

In a previous issue we referred to the recent introduction in the Vaudeville Theatre, at very short notice, of electric heating appliances, which have given satisfaction both to the lessee and to theatre-goers. The introduction of electric heating in this theatre should be of interest to the electrical profession, as marking an era in the use of electricity for warming purposes. The fact that heat produced by electricity at the present rates is more expensive than by other systems would seem to prohibit its use in large buildings, but it does not follow that the cost per unit of heat being higher the total cost of heating for a certain period will also be higher. The time of heating required is necessarily an important point in considering this matter, and with a theatre this is only a short period, say, three or four hours out of the 24. If therefore a system of heating can be employed for four hours in place of a method which requires eight hours from start to finish, it is evident that the former will be as cheap in the end as the latter, even though it may cost twice as much per unit of heat produced. It is customary during the winter, with steam or hot-water systems, to keep the fires in day and night in order to provide sufficient warmth for the hours of performance. With electric heating, however, it is only necessary to turn on the current a comparatively short period before the performance takes place. Again, most systems hitherto adopted require constant attention, and a suitable spot must be found in which to place the heating furnace and flues with safety. This part of the heating arrangement is carefully supervised by the fire insurance offices and the local authorities, and in crowded parts, where theatres are mostly situated, it is not always an easy matter to find a suitable place for these dangerous elements. Many theatres are unprovided with warming arrangements, as the gas formerly used for lighting produced more heat than was

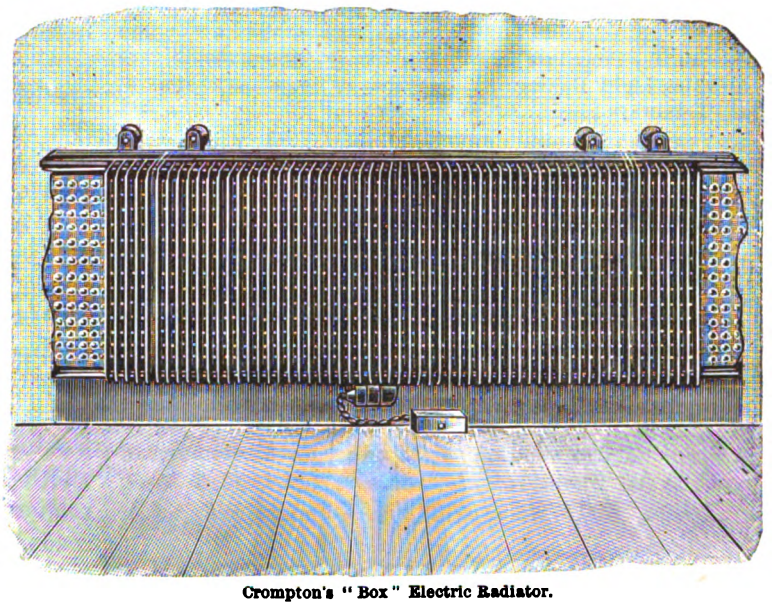
Digitized by Google

actually required. Since, however, the electric light has been introduced it is necessary to provide some system of warming, and fortunately the same agent which produces light is now available for producing a welcome degree of warmth. The use of the electric light has purified the air of the theatre and made the "theatre headache" a thing of the past, and the electric radiators now coming into use will in no way contaminate the air or offer any other objectionable feature. Small electric radiators have been in use in houses for some two years past, and their use is growing rapidly, but most engineers have hitherto discouraged any attempt to use electricity for heating on a large scale.

The authorities at the Vaudeville found it necessary to provide some system of warming, and, after considering the usual methods, they came to the conclusion that electricity offered advantages over all others. A trial was made with four large radiators of the "Crompton-Dowsing" type, taking 12 amperes, with a total of 36 square feet of heating surface. These radiators were connected with the lighting circuit, and placed in the best positions for warming the most important parts of the theatre. A week's trial showed excellent results, and it was evident that with more heating surface sufficient heat could be obtained for all requirements. An order was, therefore, placed with Messrs. Crompton and Co., Limited, of 148, Brompton-road, S.W., for the supply of electric radiators, to be fixed around the skirtings on either side and along the front of the orchestra. These radiators are of "box" form—that is to say, the plates have a front radiating surface studded with projections fixed in cast-iron cases, which are screwed by means of lugs and insulators to the walls and partition. Each box radiator is 2ft. long and 1ft. wide, and therefore offers a radiating surface of two square feet. The air is allowed to circulate between the case and the wall, so that an extra heating surface is obtained. There are six box radiators on either side and 12 attached to the partition in front of the orchestra. The latter are cased in at the back, and a good current of air is obtained by carrying the casing below the boxes containing the radiators.



Crompton's Portable Electric Radiator.



Crompton's "Box" Electric Radiator.

The four large portable radiators originally supplied on trial are arranged for use either in the stalls or at the sides. Four wall sockets are fixed on each side and four on the chair supports in the centre of the stalls. By means of these connectors, the radiators may be employed to warm the centre before the performance begins, and afterwards removed to the sides. Each radiator, portable and fixed, has a safety connector, and can be detached from the circuit at will. The radiators reach the usual temperature of hot-water pipes, and they are found to produce quite sufficient heat. The average temperature of the theatre inside after the radiators have been working a reasonable time is about 60deg.—*i.e.*, temperate—when the corridors are about 40deg. Most theatres are subject to draughts from the frequent opening of doors and from the stage, but notwithstanding these, the temperature of the Vaudeville Theatre is maintained fairly constant. Arrangements are now being made to warm the stage, and no doubt this will prevent the passage of the cold currents of air usually experienced when the curtain is raised.

The current taken by each large portable radiator is 12 amperes, and the small box radiators take three amperes each, making in all a total of 114 amperes, but as only two of the large radiators are found necessary, the current actually used for warming the auditorium is 90 amperes at 100 volts. Thus it will be seen that nine units per hour are required when the whole apparatus is in full work, and the cost—at 4d. per unit—is 3s. per hour. To warm the theatre, therefore, for a period of four hours, the cost would be 12s., and it is believed that a suitable hot-water system (particularly where gas is employed, as proposed for the Vaudeville), including attention, loss of heat in transmission, and in other ways, would cost as much. Moreover, there is the danger of a red-hot furnace in close proximity to the stage, but this is obviated by the use of electricity. Another distinct advantage makes electric heating far preferable to other systems, and that is, the perfect regulation. Thus, the whole or any number of the electric radiators may be put on or cut off at will, and there is no fear of overheating the theatre and making it uncomfortable at any time. No attention whatever is required with the electric radiators, and any of the theatre attendants can turn the current on or off according to the requirements of the case. Owing to the fact that the radiators have not to be turned on until a short time before the performance begins, the state of the weather may be judged and the heat graduated accordingly. In comparing the up-keep of the electrical plant with hot-water systems, Messrs. Crompton and Co. state that the former will in all probability be considerably less than the latter, owing to the fact that there is no furnace to burn out and no rusting or wearing out during long periods of disuse. Electric radiators are found to be very durable, they are not required to reach high temperatures, and they offer a large radiating surface. With other heating and cooking arrangements, where a far higher temperature is required, damage is often caused by leaving the apparatus connected after the cooking operation has been completed. This allows of an accumulation of heat in the electric heater which may cause it to fail altogether. The electric radiators, however, are so constructed that they cannot overheat themselves; they radiate the heat as freely as it is produced, and, as a consequence, may be left to work without attention and in perfect safety.

The installation at the Vaudeville has been carried out with the greatest care; Henley's cables, of high insulation, are used, and the switches, cut-outs, safety connectors, etc., are of the latest and best type. This being a pioneer installation, some difficulties were at first experienced with regard to the insurance rules, none of which were applicable to the special circumstances of the case. Mr. Musgrave Heaphy, of the Phœnix Fire Office, who had to pass the work, has now drafted out a set of rules with regard to electric heating which will be applicable to all work of the kind in future. The cost of installing the electric heating apparatus at the Vaudeville has been found to be about the same as for hot-water heating, and, taking all into consideration, the electric system of heating offers many advantages over the older forms of heating employed which would justify even a higher price.

It may be stated that electric radiators are on trial at several other theatres and public buildings, and in many places where other systems of heating are in use it is proposed to employ these radiators for temporary assistance in extra cold weather, or for use at a moment's notice when no provision has been made for warming the whole of a building in the usual manner. Cold corners and other places may now be warmed where other systems of heating were entirely barred on account of the danger in their use. It is proposed to use electric heating in churches, and electric foot-warmers have been suggested. The latter were to be used at the Vaudeville Theatre, but the time required for supplying and fixing them would take too long. Altogether there appears to be a field for the use of electricity for heating purposes, and it rests with the supply companies to make their charges as low as possible in order to induce business in this direction.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

LIGHT RAILWAYS.

The subject of light railways has now been brought very prominently before the public, and although we do not think that such railways would immediately be hailed as a panacea by the agricultural classes, there can be little doubt that continental competition for the supply of produce to the London market is immensely facilitated by the presence of such means of cheap transport in Belgium, France, and Denmark. The papers recently read by Mr. A. C. Pain before the Surveyors' Institution, by Mr. Meik before the International Railway Congress in London, and by Messrs. W. W. Beaumont and Stephen Sellon before the Society of Engineers, all point to the great interest shown in the subject by engineers. There can be no doubt, if capitalists can be induced to support one or two projects for light railways in properly selected districts, that a wide field will be opened up for further development. Personally, we have very strong ideas upon the subject, and we feel sure that if the present stringent regulations dealing with railway traffic are not very much relaxed, nothing of importance will result from the present agitation. Before all things, the proposed lines must be constructed cheaply, and, judging from continental practice, it will be found far the best plan to lay the lines along the sides of the ordinary public roads. In many parts of the country the waste land alongside the road is four or five yards wide, and where such a width cannot be obtained the roadway itself might be encroached upon. Many persons seem to consider that these light railways should be constructed upon the ordinary gauge, but we believe that this is a very great error, because, firstly, the rolling-stock used on such lines would never be allowed to travel upon main lines, as it would not be well enough built; and, secondly, the width required to allow for passing places would render it quite impossible to use the sides of public roads. Rolling-stock of ordinary gauge would be also far too heavy to be handled with ease by manual labour, and, in our opinion, that requirement is an essential for success.

We cannot look with favour upon the various projects which have been brought before the public whereby it is thought the advantages of the ordinary and narrow gauges can be both combined. We refer to the construction of loose bodies of trucks which can be put upon bogies of ordinary gauge on the main lines, and on narrow-gauge bogies on the light railways: all such bodies are far too heavy, and would necessitate a very strong permanent way. The ideal line is, in our opinion, of the type first brought out by Decauville, in France, and now made by many firms in this country: a gauge of about two feet, with the line laid permanently alongside the road, and having what we may term flexible ends to go right into the fields, brickyards, or other places whence goods are to be transported. The farmer must be able to take the trucks into his fields and load them there, then run them through his farmyard either by manual labour or horse power, and then the same trucks must be taken along the light railway to the station on the main line.

Digitized by Google

If a light railway is to be made in such a way that it cannot enter the farmyard, the farmer will be obliged to load his produce into carts as he does at present, and once in a cart he may as well avoid transhipment by carting it to the station of the main line. The portable portions of the track in the fields and the wagons could either be let on hire to the farmer by the light railway company, or he might be supplied gratis with the wagons and be required to purchase the portable portion of the track. The chief point, however, is to put the farmer himself to as little expense as possible. He is now stated to be in the last stage of poverty, and it is impracticable to burden him further. The lines should be worked by the overhead wire system of electricity, the wires being carried upon side brackets standing out from posts in the hedgerows. The potential used would be, say, five hundred volts, and if such light railways radiated from the main-line station the service of trains upon them might be so arranged that the maximum output from the generating plant would not be greatly in excess of that required for, say, a single train. The speed required would not exceed eight to ten miles per hour, and passengers could be carried on the well-known jaunting-car system. No system of storage of electricity is yet sufficiently cheap to be of service, either in the trains or in the generating station.

The crux of the whole question is, however, the obtainment of capital to carry out the projects. Nothing will be done if it is necessary to apply to Parliament for powers for each separate scheme, as the system is far too expensive and leads to enormous over-capitalisation. We believe that the only practicable method is to offer a guarantee out of the rates, and call upon the public for a portion only of the capital required. The Board of Trade might well be made the final authority before which evidence would be given, and the county or district councils would be the bodies directly in touch with the promoters. All appeals would then be heard by officials of the Board of Trade. If this method were carried out, and powers for construction could be cheaply obtained, such light railways might be expected to pay from 3 to 4 per cent. dividends. As traffic increased it would be possible to improve the lines, but at present the cheapest possible system is, we are firmly convinced, the only one which can be profitably employed.

CORRESPONDENCE.

Justice needs that both be heard."

TESTING INSTRUMENTS.

SIR,—We notice a letter in your issue of 1st inst., under the above heading, evidently referring to our catalogue, which you lately noticed. Our attention is particularly directed towards the last sentence of this letter as to copying original designs of other makers.

Mr. Paul has apparently forgotten the old saying advising people what not to do when living in glass houses. We have before us a list of his manufactures (List No. 5) in which we find but three illustrations besides those of the galvanometer he refers to. Two of these (Nos. 5 and 6) are practically copies of our original designs, and will be found in our catalogue of a quarter of a century ago; whilst the third (No. 4) bears a wonderful family likeness to an illustration given in a catalogue published many years ago by M. Carpentier, of Paris. For our own part we make no objection, believing imitation to be the sincerest form of flattery.—Yours, etc.,

London, March 6, 1895. ELLIOTT BROS.

REVIEWS.

Dynamo Construction: A Practical Handbook for the use of Engineer-Constructors and Electricians-in-Charge By JOHN W. URQUHART. Price 7s. 6d. Second edition, revised and enlarged. Crosby Lockwood and Son.

That this work has passed through a first edition and that a second has been called for shows that, whatever opinion a critic may hold, there is a demand for a simple descriptive book on the subject. The best friends of Mr. Urquhart cannot accuse him of originality, but they may claim that he is an energetic seeker amongst current literature for that which will assist him in compiling books. Such compilations have considerable value, for in these busy times it is almost impossible for everyone to find time to make himself acquainted with the various improvements in all directions which have taken place in dynamo work. Very broadly speaking, there are two classes of technical books—one descriptive of what has been done, the second dealing with principles to show how it is and why it is done. Both have their uses. This book is of the first kind, and of its kind is good.

PARLIAMENTARY PROCEDURE AS AFFECTING LIGHT RAILWAYS AND TRAMWAYS.

The members of the Society of Engineers, at a meeting held at the Westminster Palace Hotel on Monday, Mr. Wm. George Peirce, president, in the chair, listened to a paper by Messrs. W. Worby Beaumont, M.I.C.E., and Stephen Sellon, A.M.I.C.E., on "Parliamentary Procedure as Affecting Light Railways and Tramways."

In the first part of this paper the authors referred to the stagnation which has for years characterised the light railways, tramroads, and tramways construction branches of engineering. This they consider is chiefly due to the heavy capital burden with which most projects are loaded, capital which is not required either for the construction of working of the lines, and which, moreover, is never available for either of these purposes. The costs of obtaining permission to construct a line, even where called for by the inhabitants of the districts to be served, are at present excessive, as a result of the procedure according to which a scheme is not examined as to its merits by any responsible body or department before all the costly machinery necessary for meeting opposition from any source is put in motion. This introduces the speculative element into the first stages of the promotion of a scheme, inasmuch as considerable sums of money have to be provided to put and keep this legal and other machinery in motion and to buy off opposition. This money has to be provided before it is known that the scheme will receive or is likely to receive assent, and hence the money provided for these purposes is only advanced on extremely heavy terms. The authors referred to these questions and to the heavy expenses incurred to meet the Board of Trade rules, the rules as to standing orders and others framed under statutes.

As an example of the necessity for more freedom in the exercise of discretion with regard to mechanical and minor matters affecting tramroads, it may be mentioned that whilst every Tramway Act permitting the use of mechanical traction requires all steam locomotives to be fitted with automatic speed governors and brakes, a requirement which the Board of Trade officers are bound therefore to enforce, no such requirement is demanded by them with regard to electrical tramcars. They do not feel bound to enforce it because electric locomotives are not steam locomotives. Part of the South Staffordshire tramways is worked by 17 electric motor cars, weighing six tons each, where formerly it was worked by steam locomotives. On this piece of line no such automatic governors and connected brakes have ever been found necessary, neither have they at Leeds or Blackpool. Clauses such as these inserted in Tramway Acts hamper the engineer in the proper working of a line, and the Board of Trade official becomes a mere clerk of works following a specification, whereas he should be free to insist on

Digitized by Google

or to relax provisions with regard to mechanical details according to circumstances and to the requirements of the case as affected by progress in construction, and by the demands of a district or by the kind of traffic.

The authors propose various relaxations in the Board of Trade rules, and propose that with regard to any *bonâ fide* schemes the proposition and proof of public utility should be heard first somewhat after the manner of a Local Government enquiry, and that opposition should be heard afterwards if the proposed preliminary enquiry gives encouragement to proceed. According to present arrangements, the Standing Orders Committees give assent in response to a prayer that the scheme be allowed on the grounds of its public advantage, and yet the public advantage thus admitted and the admission of the good grounds of the prayer may count for nothing in the face of opposition of one man or one Board of Trade rule, which may be founded on obsolete or antiquated statutory requirements.

The authors propose that agreements entered into before date of standing orders should come before the committee, so that unreasonable sums should not be added to the necessary capital by way of bought-off opposition or excessive promises to pay for accommodation by speculative advances which may ruin the prospects of a scheme from the first and make high rates and fares necessary. The authors also propose that instead of two separate committees, one of each House, there should be a joint committee so that the expense should be that of one enquiry instead of two, but they propose that the decisions may be either joint or independent as may in each case seem needful. The authors also propose that no clauses should be inserted in a Bill at the instigation of opposing parties without investigation by the committee, and also that the relation between the proposed capital and reasonable cost of construction and equipment should be considered by the committee, as restricted debentures provide no protection against over-capitalisation. Numerous other modifications are referred to as necessary to secure facilities for the construction and working of tramroads and tramways which shall place them on a footing comparable with that which obtains in France, Belgium, and elsewhere.

The authors consider that light railways are required in some districts, but that there is a greater field for the profitable construction and working of tramroads and tramways if the proposed modifications in procedure and the proposed relaxations in rules are made. The paper concludes with reference to the recent Board of Trade Committee on Light Railways and reproduces some of the proposals made by several members of the committee who disagreed with the general report as insufficient, and at offering very little aid towards a settlement of the questions raised by the Board of Trade reference or towards definite proposals on the questions raised by the President of that Board.

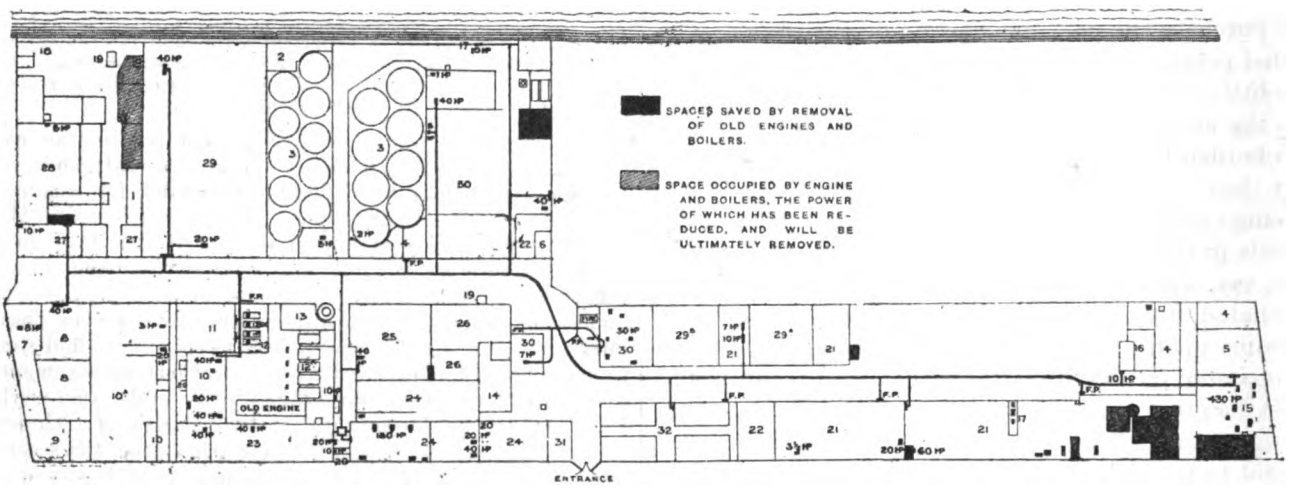
ELECTRIC TRANSMISSION OF POWER.

BY ALEXANDER SIEMENS.

Some three months ago a paper was read by Mr. Alexander Siemens on "Electric Transmission of Power" before the North of England Institute of Mining and Mechanical Engineers. This paper, of which the following is an extract, is published in the *Transactions* of the Federated Institution of Mining Engineers:

The writer's principal object is to lay before the members some results of the adoption of the electric transmission of power at the Woolwich works of Messrs. Siemens Bros. and Co., where the change was commenced about two years ago, and is even now not quite completed. The diagram, Fig. 1, shows a plan of the works, which cover about six acres of ground.

At the central station, 12A, there are five boilers working at a pressure of 130lb. per square inch of the "gunboat" type—*i.e.*, two-flued multitubular boilers, each 18ft. long and 9ft. in diameter. They are hand-stoked, and supply steam to the machinery of the central station, to the steam-engines driving the guttapercha shop, and for heating purposes. Condensers are placed on the roof of the boiler-house, each sufficient for 25 i.h.p. These condensers consist of two cylinders, one placed



SPACES SAVED BY REMOVAL OF OLD ENGINES AND BOILERS.
SPACE OCCUPIED BY ENGINE AND BOILERS, THE POWER OF WHICH HAS BEEN REDUCED, AND WILL BE ULTIMATELY REMOVED.
OLD ENGINE
ENTRANCE

FIG. 1.

inside the other, forming an annular space into which the steam passes from the engines while cold water is trickling down the outside of the larger and the inside of the smaller cylinder. The condensing water is used to feed the boilers and to supply the guttapercha and indiarubber washing-tanks, and the condensed steam is allowed to run to waste. In the engine-room, 12, which measures 42ft. by 30ft., there are four steam dynamos, each capable of giving a current of 1,500 amperes at 120 volts pressure when running at 350 revolutions per minute. All four dynamos are exactly alike, being two-polar drum armature machines of the Siemens H.B. $^{24}/_{36}$ type, shunt wound, and

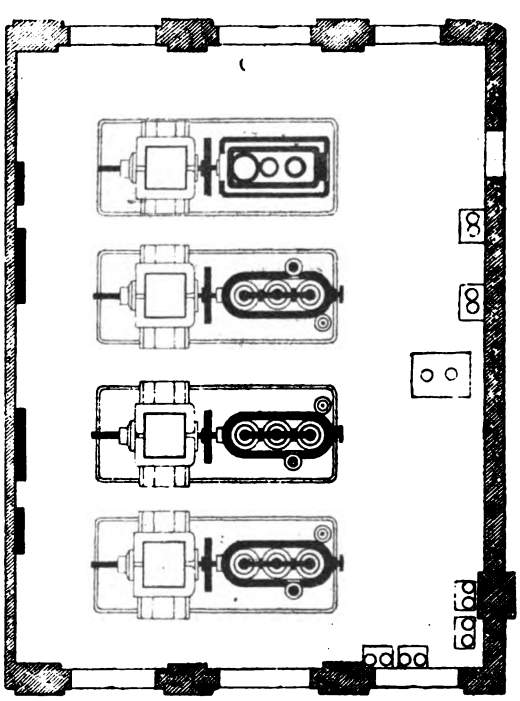


FIG. 2.

fitted with switch and resistances for varying the exciting current by hand. Three of the dynamos are driven by three Willans III compound condensing single-acting engines, and the fourth is coupled to a Belliss compound condensing double-acting engine, Fig. 2.

The four generating sets are coupled in parallel to an omnibus bar, with ampere indicators showing how much current each set is giving, and from this bar the main cables are laid to the various departments, a safety fuse and an indicator being fitted in each circuit. Provision is also made on the switch-

Digitized by Google

board for coupling two of the generating sets in series, when a current of 240 volts pressure is required at any part of the works, Fig. 3. The return cables are also all joined to one bar, and from this bar the current passes through a registering meter before it returns to the dynamos, Fig. 4. In this way an exact record is kept of the current generated at the central station. The total length of cable laid between the switchboard in the engine-room and the distributing-boards in the various departments is a little over 18,000ft., the area of the cross-section of the copper conductor varying from ¼ to 1½ square inches. Each department has its distributing-board, to which the current is brought from the central station by one or more main cables; it is fitted with a registering meter, and with fuses for the branch cables which lead to the various motors in the department, Fig. 5. All the main cables have the copper conductor insulated by impregnated jute, covered with lead, which in its turn is protected by tarred jute and steel ribbon, again covered with jute and compound. These cables are laid directly into the ground without farther protection, and have never given any trouble. Owing to the rules of the London County Council, each motor is completely enclosed, and by no means readily accessible. Some motors are quite closed in with sheet iron, so that nobody may come in contact with moving parts.

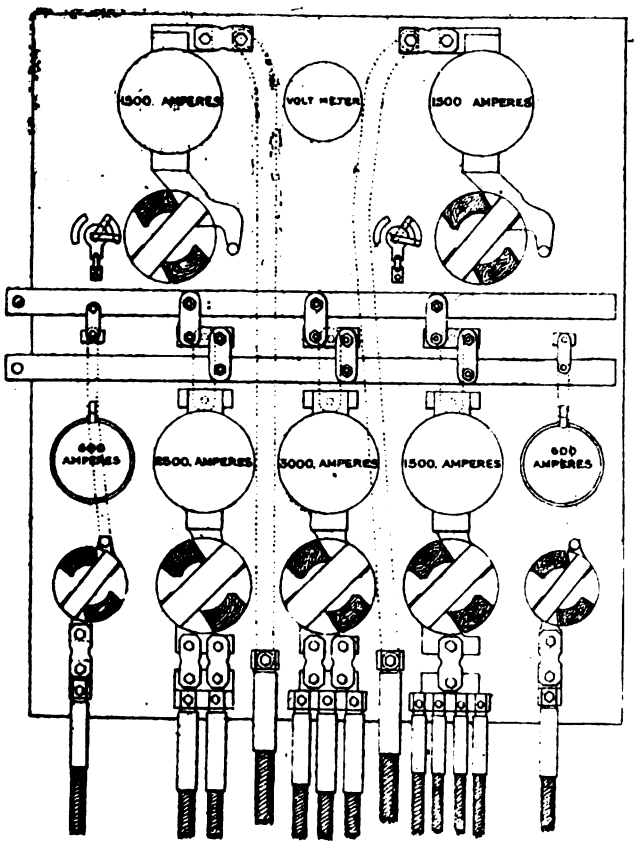

FIG. 3.

In other instances an iron framing covered with iron netting is put round the motor, and this arrangement has the advantage of permitting a free circulation of air. At the present time 72 motors are in use, varying in size from 100 b.h.p. to ⅛ b.h.p, and capable of giving a total of 1,407½ b.h.p.

The output of the central station is 1,200 i.h.p., which with an efficiency of 86 per cent. gives 1,130 e.h.p. available at the central station, or, roughly, 1,000 b.h.p. at the moters in the workshops. With regard to these figures, it should be remembered that the whole plant is capable of producing from 25 to 30 per cent. more output, when required for a few hours, without any danger of straining any part of it, and this is the safeguard to which the author has already called attention, and which ensures the satisfactory working of such an installation. Before the electric transmission was introduced, 18 steam-engines were employed, capable of yielding altogether 1,446 i.h.p. These correspond to about 1,150 b.h.p. then available for driving machinery. Seven of the old steam-engines, giving about 380 b.h.p., are still in use, so that the total power now at disposal for motive purposes is 1,787 b.h.p., while, in addition, the central station furnishes current for 72 arc lights and about 1,600 16-c.p. incandescent lights.

A comparison of these figures will at once show that the works have been considerably extended since the first steam dynamo was started, on June 20, 1892, and for this reason it has been rather difficult to find out how the cost of power at the present time compares with that of working steam-engines alone. Another circumstance which made such an enquiry complicated was that the work on a large cable contract this year increased all expenses of fuel and labour to such an extent, that the preceding years cannot be compared with it in order to determine the exact saving that has been effected. In former years, cable work of equal duration increased our consumption of

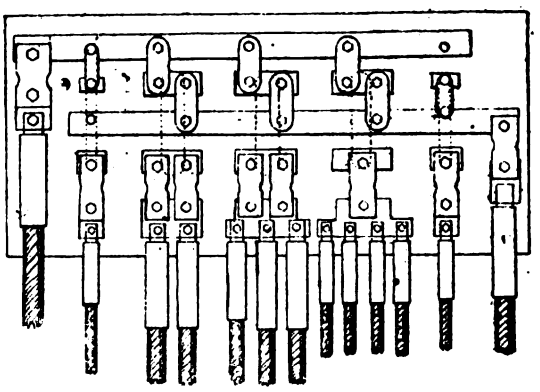

FIG. 4.

coal by nearly 5,000 tons, but this year the increase has not been more than about 2,000 tons, so that an actual saving appears to have been effected of about 3,000 tons of coal. The steam-engines and boilers of the old installation were tended by 10 stokers and nine engine-drivers, while at the present time eight stokers are employed, of whom three attend to the old boilers still in use, and five engine-drivers, three of whom attend to the old engines. The electrical part of the machinery in the central station is attended to by one electrician and a boy, while the motors are attended to by the oilers of the various departments. When the arrangements are completed, all auxiliary boilers will be abolished, and a farther saving of attendants will be effected.

As far as they go, these comparisons prove that the electric transmission has been economical, but in order to obtain satisfactory information as to the performance of the plant a series of tests were conducted by the experiment department, under the direction of Dr. Eugin Obach, as follows: The boiler tests and engine tests were carried out separately in two series. The first series was intended to determine the weight of steam generated per pound of fuel, and this test extended over a month of ordinary working, and included all necessary coal for lighting up. The second series was intended to determine the weight of steam required by the engines per Board of Trade unit delivered to the distributing bars of the central-station switchboard. This was found by exhausting the engine under test into the main condenser and measuring the overflow from the air-pump, taking care that no other water could mix with the overflow. These engine tests were subdivided again into two kinds: (1) running on steady artificial loads of about a quarter, half, three-quarters, and full load; and (2) running on the ordinary day load. The second set of tests was undertaken to see if a varying day load required the same weight of steam per Board of Trade unit as a perfectly steady load giving the same output. This was found to be the case: the point obtained by the day-load test fell exactly on

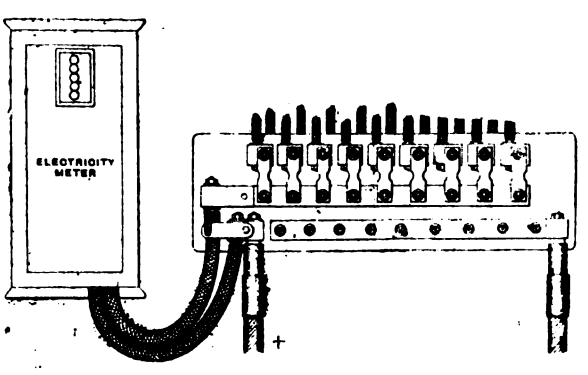

FIG. 5.

the curve obtained from the steady-load tests, Fig. 6. As factors involved in the cost of generating a Board of Trade unit, the steam taken by all the auxiliary pumps had to be taken into account. This was done by condensing the steam exhausted from the feed-pump, air-pump, and circulating-pump and weighing the water discharged. As the feed-pump supplied water to all the boilers, only a part of its steam was taken in the proportion which the air-pump discharging from the condenser bore to the total feed water.

The coal was weighed out of the barges in quantities of 15cwt. at a time; a reliable steelyard was slung on the crane hook

and compared from time to time with standard weights. A sample was taken from each skip, and all the samples were afterwards ground up and well mixed, thus affording a thoroughly representative sample of the coal for analysis. The water was fed from a feed-water heater into a measuring tank holding 6,270lb.; this tank stood over a shallow supply tank, and could be emptied into it through a 6in. valve. The temperature of the feed water was frequently taken. The test was started with a perfectly clean stokehold floor, the furnace having been supplied from a separate store of coal, which was locked up as soon as the use of the weighed coal was commenced. The water levels in the gauge glasses were marked, and the steam pressures and state of fires were noted. A log-book was kept, with the following entries: (1) time of shift (eight hours); (2) name of person in charge of shift; (3) boilers in use; (4) amount of coal weighed into bunkers; (5) state of bunkers; (6) pounds of water fed during shift; (7) mean temperature of feed water; (8) mean steam pressure; and (9) water level in feed-tank at end of shift. At the end of the first week the boilers were worked down to the same condition as at starting, and all the coal used up, feed water noted, etc., to form a check. Then the test was continued, and went on until the month was up, all the conditions being the same at the end.

The engines and dynamos were run for five hours on each load—that is, four tests on each type of engine, eight tests in all on the steady loads. Simultaneously, the auxiliary pumps,

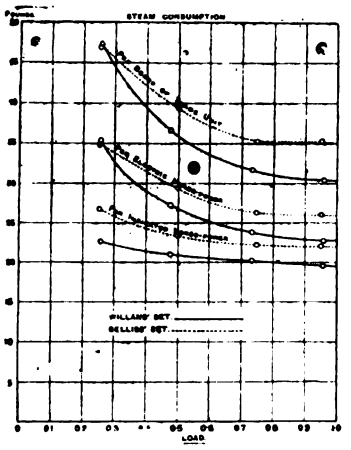

FIG. 6.

etc., were measured, and the electrical output of the dynamos was gauged. The engines were indicated every half-hour, giving 10 sets of diagrams for each load. To ensure simultaneous readings of the electrical instruments and indicators a whistle was blown. The electric current was measured in two ways: (1) by three Siemens ammeters A53 type, which were frequently compared with the standards, in the positions in which they were used, and were set up in such a way as to have no disturbing effect on one another—the readings of these three instruments were adopted; (2) by a large plate of German silver carrying the main current, and having its difference of potential measured at two points by a delicate galvanometer. The two methods described above gave very consistent results, particularly at the two lower loads. The volts were measured by (1) a Siemens torsion galvanometer, checked with the Clark standard cell before and after all the tests, and found correct; (2) a Weston standard voltmeter. These two methods also agreed, the difference being quite negligible. The voltmeters were placed at a distance from any machines or cables carrying current. These readings were adopted. To ensure the greatest possible accuracy in the efficiency tests, all the steam-engine indicator springs were tested by an independent manufacturer, and a correction table applied to the indicator cards.

In making up the cost of a Board of Trade unit, the following items were included: coal, including cost of delivery to bunkers; water, auxiliary pumps, etc.; oil, waste, and sundry stores (for last six months); removal of ashes, engine-room drivers and machine-tenders, electrician and switchboard boy, stokers, and repairs. This cost only refers to the Board of Trade unit at the switchboard, and takes in no charges connected with the distribution plant. The actual results obtained are stated below.

Boiler Efficiency.—Boilers of gunboat type:

	Square feet.
Nos 3 and 4 boilers, heating surfaces—	
Tubes	1,033
Flame-boxes	222
Total	1,255
No. 5 boiler, heating surfaces—	
Tubes	1,110
Flame-boxes	215
Total	1,325

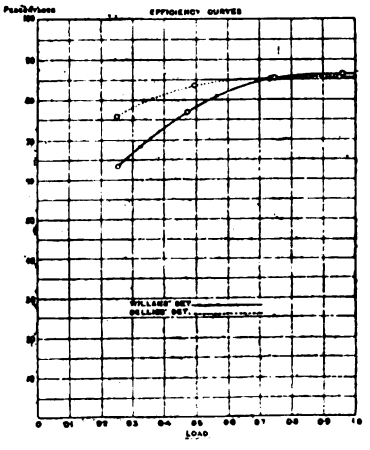

FIG. 7.

The grate area of boilers Nos. 3, 4, and 5 was 41 square feet for each. The duration of test was 356½ hours. The total of boiler-hours was 988. Nixon Navigation coal was used, the mean thermal value of four samples being 14,221 British thermal units. The evaporative power at 212deg. F. was 14·65lb. of water per pound of coal. The mean carbon value of the coal was 0·993. The coal burned per boiler per hour was 625lb., and per square foot of grate area per hour it was 15·25lb.

The water evaporated per boiler per hour was 5,576lb. The weight of water evaporated per pound of coal (including coal used in lighting fires) into steam at a pressure of 127lb. per square inch was 8·923lb. The weight of water evaporated per pound of coal from and at 212deg. F. was 10·083lb. The weight of water evaporated per square foot of total heating surface per hour was 4·42lb. The weight of water evaporated per square foot of grate area per hour was 136lb. If the coal used

Digitized by Google

in lighting up be neglected, the evaporative efficiency becomes 9·16lb. of water per pound of coal at a mean pressure of 127lb. per square inch, and 10·35lb. of water per pound of coal from and at 212deg. F. The annexed experiments were made on steady loads (resistance frames):

DAY-LOAD TESTS OF FIVE HOURS, THE VARIATION OF LOAD BEING ABOUT 15 PER CENT.

	Willans engine, etc.	Belliss engine, etc.

Weight of coal used per electric horse-power per hour (pounds)	2·62	2·93
Weight of coal used per Board of Trade unit (pounds)	3·51	3·93
Proportion of full load	0·778	0·789

These engines were not indicated, owing to the impossibility of taking simultaneous readings. From these experiments two diagrams have been prepared, one showing the steam consumption per Board of Trade unit, per electric horse-power, and per indicated horse-power (Fig. 6); and the other the efficiency of the steam dynamos (Fig. 7). It will be seen that the steam consumption of the Belliss engine was greater than in the Willans, but it should be stated that this was the first engine of its kind ever built of that description, and that it has the worst position as far as the exhaust steam is concerned. On the other hand, the efficiency shows to greater advantage in the Belliss set, the dynamos being identical. After the consumption of fuel and of water had been determined by these experiments, the value of the stores issued to the central station for the last six months was ascertained, together with the wages paid and the cost of the repairs done to the central station and to all the electric plant, including motors.

The output of the station had been at the rate of 1,797,120 Board of Trade units per annum, representing a load-factor of 0·285. The actual cost per Board of Trade unit was, therefore, for the six months ending October 31, 1894:

	Per Board of Trade unit. Willans. Pence.	Belliss. Pence.
Coal (including cost of delivery and removal of ash), 17s. 5d. per ton. Willans, 3·41lb.; Belliss, 3·95lb. per Board of Trade unit	0·3180	0·3680
Water (7½d. per 1,000 gallons)	0·0228	0·0264
Stores, oil, waste, boiler fluid, etc. (taken from last six months' consumption)	0·0416	0·0416
Wages, stokers, trimmers, drivers, labourers, electrical assistant (half time), and switch-board boy	0·0977	0·0977
Steam for auxiliary pumps, feed (only 0·7 taken), air, and circulating, water 0·003d., coal 0·026d.	0·0290	0·0290
Repairs to central-station plant and motors	0·0802	0·0802
Total cost per Board of Trade unit	0·5893	0·6429
Total cost per electric horse-power per hour	0·440	0·480

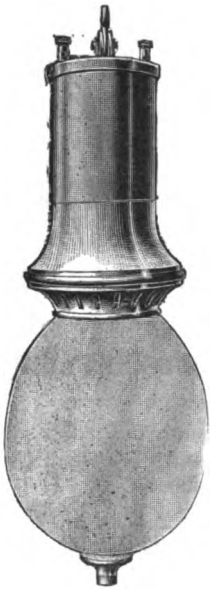
The cost for steam supplied to auxiliary pumps, etc., is too high, as there was only one set exhausting into the main condenser during the tests, and the steam of one circulating pump and the air-pump was charged to this set: probably a very little more steam would suffice for the full working load on the condenser. This cost is that of a Board of Trade unit at the switchboard in the central station. The loss of energy in the cables is not more than 5 per cent., and the average efficiency of the motor being taken at 90 per cent., the cost of a brake horse-power, or 746 watts, may therefore be taken at 0·515d. per hour. No attendance has been charged to the motors, and the expense of oiling is very trifling, especially in motors fitted with Meneely bearings, of which a model was shown. Such bearings were applied to the three bearings of a Siemens H.B. : $^{15}/_{20}$ motor, developing about 40 b.h.p. at 360 revolutions per minute in driving part of the machines in the lead-cable sheathing-shop. Two of the journals are 2¾in. in diameter by 7 3-16in. long, while the third is 3¼in. in diameter by 6 7-16in. long. During the first week's run, one of the roller bearings got rather hot, but not sufficiently so to necessitate stopping the motor; and since that time—the beginning of July, 1893—they have all been running satisfactorily. The consumption of oil after the first few weeks was at the rate of one pint per month for the three bearings.

In order to make a comparison between the outlay for an electric plant and for a steam plant, the author has had a table prepared showing the cost of the old steam-engines and boilers at Messrs. Siemens's works, together with the cost of foundations, erection, and of the chimneys. A statement, similarly, of the cost of the new boilers, of the pipework, of the auxiliary engines, the condensers, the steam dynamos, the cables, motors, switches, and all accessories has been also prepared. In the old steam plant of 1,446 i.h.p., taking into account the long lengths of shafting that had to be driven, the author does not think that more than 60 per cent., or 867 b.h.p., was really utilised. On the other hand, there are now 1,407 b.h.p. available at the motors, and 240 h.p. devoted to electric lighting purposes. The author does not wish to publish the exact costs, but the capital outlay per brake horse-power was 30 per cent. higher in the case of the old steam plant than for the present electric central-station plant. Moreover, the load-factor—viz., the proportion of the actual output of the central station to the possible output, which, as stated above, is 0·285—shows that we can connect to the present generating plant many more motors without much fear of overloading it. There can, therefore, be little doubt that for new works electric transmission of power is certainly more economical than the employment either of separate steam-engines or of transmission by belts or ropes.

Whether a change from the old system to electric transmission can be recommended depends entirely on local circumstances, and this question can only be ascertained by carefully weighing all the factors that come into play. Generally speaking, electric transmission is most applicable where power is wanted at a number of places scattered over the works, and especially in and about mines and collieries. Such a case has lately been investigated by the writer's firm, and they have made an offer to replace various engines, exerting altogether about 800 b.h.p., by an electric plant, comprising a central station similar to that at Messrs. Siemens's works, but having only three boilers and three sets of steam dynamos, all switches, cables, and motors to do the above work for a certain sum. By this conversion the colliery owner would save sufficient money—counting 15 per cent. of his outlay for interest and depreciation—to repay the outlay in 10 years, or, in other words, the cost of working the plant for a year would be less than the present cost by an amount equal to 25 per cent. of the outlay. These figures show that there is a wide field for successfully applying electric transmission of power—in works as well as in mines—where electric motors must be especially welcome, as they do their work without forming any by-products that have to be dealt with by costly contrivances. In these times of ever-increasing competition it is well worth while to utilise all advantages that science places at the disposal of industry, and anything that increases the amount of power at our disposal for each pound of fuel consumed should meet with hearty support in this great centre of mining and industry.

THE "RICHARDSON" BRITANNIA ARC LAMP.

The type of arc lamp illustrated herewith is suitable for both internal and external illumination. It has been specially



designed for working on central-station circuits, and is readily handled and trimmed by those unskilled in the use of arc lamps. The lamp is of the differential-focussing brake-wheel type, and is mechanically and electrically as perfect as possible. The magnets are of a large area, and are, therefore, not liable to become unduly heated. The working parts are few, and, having a most perfect feed, the light is absolutely steady. We are informed that this lamp, which is made by Mr. A. W. Richardson, of Patricroft, near Manchester, has been adopted by many engineers and companies, and that it is at work on most of the existing Corporation electric light supply mains.

THE RECENT ACCIDENT AT BRISTOL.

Major Cardew, R.E., has held an enquiry this week at the Guildhall, Bristol, as to the circumstances of the fatality which happened on February 25 in one of the transformer-rooms of the Bristol Electric Lighting Department, by which Robert Coleman lost his life. Mr. D. Burges (town clerk) and Mr. Wise represented the Corporation, and there were also present Mr. George Pearson, chairman of the Electric Lighting Committee, and Mr. Faraday Proctor, the chief electrical engineer.

Wm. J. R. Wilcocks, an improver at the Corporation electric light works, said that on February 25 he was at the Old Market-street transformer-room with Coleman, who removed the fuses of the high-tension fuse-board. He then proceeded to dust the board and brass terminal, and at the commencement did so with his right hand, upon which he had an indiarubber glove. He meanwhile kept his left hand in his pocket; but after a time he used it for holding the other end of the duster, and worked with both hands. In this way he cleaned three of the terminals, and was doing another, when he looked up as if to speak to witness. As he did so the knuckles of the left hand touched the terminal, the deceased uttered a sharp cry, and went up on his toes perfectly rigid. His hand was not clutched on the terminal, but there was a "sizzling" noise. He seemed perfectly rigid, and looked unconscious. He was leaning towards the board, and that kept him in contact. Witness went behind him, caught his coat, and pulled him off. This was a matter of a few seconds. Artificial respiration was tried. Dr. Page was sent for, and he continued to try artificial respiration, but without avail.

William Coleman, brother of the deceased, gave evidence of the deceased having had 13 years' electrical experience, 11 years being at telephone works, and the remaining two years at Messrs. Siemens Bros. and the Corporation electric light works. The deceased was aware of the danger of touching any high-pressure terminal.

Dr. Page gave evidence that he had made a *post mortem*, which led him to believe death was due to electric shock. The death was practically instantaneous.

With Mr. Faraday Proctor, and several others connected with the electrical department, the inspector then went to the cellar where the transformers are placed, at 76, Old Market-street. There **Mr. Faraday Proctor** explained how the accident occurred. The deceased had simply to dust the fuse-board, and should have done so using only one hand, and that protected by a non-conducting indiarubber glove. Instead he used both hands, his left being unprotected. He took the duster, one end in each hand, and placing it in a U-shaped slot in the terminal, moving the duster backwards and forwards. He need not have dusted the slot. While doing so he looked towards another employé of the Corporation, as if about to speak, and inadvertently touched with his bare hand one corner of the terminal in which the slot was. He at once fell forward over the board, but was pulled back by the other employé, Mr. Wilcocks. He did not touch both terminals; the current, which came from the central generating station at a pressure of 2,000 volts, passed through his body to the ground and killed him.

The **Inspector** made a series of suggestions, with a view of increasing the safety of those who might have to work in the cellar. One was that there should be a substantially-made guard of vulcanite, or other non-conducting material, around the terminals where they, bare of any insulation, projected on the fuse-board; and that the bare terminals and projected fittings be painted with the non-conducting red solution used for such work. Major Cardew further suggested that, as there was plenty of room in the cellar, there might be a reserve board to which the high-pressure current could be switched while one board was being cleaned, the floor of the cellar be laid with asphalte so as to obviate danger of earth connections, and indiarubber boots used as a precaution.

Mr. Faraday Proctor made a note of the suggestions, which it was understood, although not expressly stated, applied to the other transforming stations (14 in number) owned by the Corporation.

THE PROPOSED PACIFIC CABLE.

The following is a copy of further correspondence between Sir Charles Tupper and Sir John Pender on the subject of a proposed Pacific cable:

SIR CHARLES TUPPER TO COLONIAL OFFICE.

Victoria-chambers, 17, Victoria-street,
London, S.W., Dec. 12, 1894.

Sir,—I have observed that in the recently issued parliamentary paper [C. 7,553] relating to the Colonial Conference at Ottawa a letter from Sir John Pender to the Marquis of Ripon, dated June 2, 1894, enclosing certain correspondence between him and myself, is printed (pages 367-371).

After the date of that communication, however, a further correspondence took place between Sir John Pender and myself on the subject at issue, which should be read in conjunction with that presented to Parliament in the Blue-book referred to.

I therefore beg to enclose herewith a copy of this later correspondence for the information of Lord Ripon, and for publication if his lordship sees no objection.—I am, etc.,

CHARLES TUPPER.

SIR CHARLES TUPPER TO SIR JOHN PENDER.

Office of the High Commissioner for Canada,
17, Victoria-street, London, W.C.,
June 4, 1894.

Dear Sir John Pender,—In reply to your letter of the 30th of May, I beg to remind you that we joined issue on the following points: 1. Whether the "existing service was established solely by private enterprise." 2. Whether the life of a cable is 14 years. 3. Your assertion that my "description of the existing system as a monopoly cannot be justified." 4. That a Pacific cable has no strategic value.

I respectfully submit that the admission that the "existing service" has already received Government subsidies exceeding £2,000,000 settles the first issue.

You reject the authority of the Berne list, for the accuracy of which I supposed you were responsible, quoted by me in support of my contention as to the life of a cable, but you have not met my quotation from a recent speech of your own, which showed the life of a cable to be nearer 25 years. Permit me to quote the further evidence of another high authority on that question—your late colleague, Sir James Anderson—who was knighted for laying the first successful cable between England and America. In October, 1886, at a meeting of the Direct Spanish Telegraph Company, Sir James Anderson, presiding, said: "They estimated the life of the Barcelona cable at 25 years." It had then been in operation 13 years, and great improvements have been made in the manufacture of cables since the Barcelona cable was constructed. I think I may now fairly consider the second part of our controversy disposed of.

As to the "monopoly" question, you intimate that Mr. Raikes was misled by Mr. Fleming. I will now give you an authority which I am sure you will respect, for it is your own. I find the following statements in a letter written by you to Sir Henry Holland, dated April 18, 1887: "If reference is made in any way to the existing companies as a monopoly, my answer is that it has been so created by the great energy with which the company have carried on their extensions. . . . I would also draw your attention to the fact that, while it has been made a monopoly through the circumstances I have stated," etc. While this public record remains, you will, I imagine, hardly repeat the statement that I am not justified in considering the "existing system as a monopoly."

As to the question of the strategic value of a Pacific cable, not only the *Globe*, from which I quoted, but the Press generally of this country, of Australasia, and Canada have been emphatic in their declarations in opposition to your views, nor can I see how any disinterested man can hold any other opinion. The cable communication between this country and India and Australasia passes through several foreign countries, and in the contingency of a European war could not be relied on.

You say, in reply to the statement in the *Globe*, that, in the case of your cable between Aden and Bombay being injured communication with India would be interrupted, that you have three other routes practically under your control. I suppose the three routes you refer to are those given in the official maps of the International Bureau: (1) through Russia, Siberia, Japan, and China; (2) through Germany, Russia, and Persia to Kurrachee; (3) through Constantinople and the Euphrates Valley to Kurrachee.

I am not aware that these long overland lines are under the control of the Eastern Telegraph Company.

For Imperial purposes, the first and second routes present insuperable difficulties, and I do not think that your experience in telegraphy with India will lead you to consider as reliable the Euphrates Valley line, which belongs to the Turkish Government, and passes through a country bristling with physical difficulties, rendering the maintenance of good communication almost impossible. You must, however, admit that if the Indian land wires in the neighbourhood of Kurrachee and Bombay were interrupted, all communication by telegraph between these towns and Calcutta, Madras, and Australia would require to be transmitted to Europe for retransmission through the only remaining route open to the East—viz, through Russia, Siberia, Japan, and China. An all-British line, *vid* Canada to Australia, remote from any hostile influence, might at any moment, therefore, become vital to the best interests of the Empire. As to the financial prospects of this enterprise, I am glad to find that you have revised the estimate you submitted to Lord Ripon in April, and now make the deficit £48,000 instead of £120,000, at which you then stated it. I beg to suggest that if you will place the amortisation of the cable at 25 years, and add the receipts of the large volume of United States and Canadian traffic that will be created by a Pacific cable, and make fair allowance for the usual increase of traffic, your latest calculation will be considerably modified. Allow me to add that your adherence to 14 years as the life of the cable in order to show the scheme financially impracticable will in my opinion convince many persons that the enterprise cannot be condemned by fair calculations.—I remain, etc.,

CHARLES TUPPER.

Sir John Pender, G.C.M.G., M.P.

P.S.—I am sending this letter to the *Times*.

SIR JOHN PENDER TO SIR CHARLES TUPPER.

The Eastern Extension, Australasia, and China Telegraph Company, Limited,
Winchester House, 50, Old Broad-street, London, E.C.,
June 6, 1894.

Dear Sir Charles Tupper,—I have received your letter of the 4th inst., from which it is quite clear that our views on the Pacific cable question are so divergent that no practical purpose will be served by continuing the correspondence any longer.

Digitized by Google

But before closing it permit me to briefly deal with the principal points raised in your last letter, and to express the hope that the facts and figures which have been elicited by the correspondence may be found useful to the Ottawa conference, and more particularly to the investing public, who will eventually have to decide the question, if it is to take a practical shape.

With regard to the first point, I think any unprejudiced person reading my previous letter will have been convinced that the pioneer service to Australia was established solely by private enterprise, and that the Government subsidies granted years afterwards for an entirely different purpose have no bearing on the argument.

As to the second point, it is true that there are cables still working which were laid 25 years ago; but, on the other hand, many cables equally well manufactured and laid have been known to require entire renewal in as short a time as 12 to 17 years after they have been submerged. In short, the life of a cable is notoriously uncertain, depending very largely on the locality and nature of the bottom over which it is laid, and it is therefore impossible to accurately measure such an unknown quantity. I have never, however, asserted that a Pacific cable would last only 14 years. All I have done is to base my calculation for amortisation on the period fixed by the Wellington conference for the proposed guarantee—viz., 14 years.

If, however, we take 20 years, which is the more usual period for subsidy or guarantee arrangements of this kind, as the basis of calculation, the financial result to an investor would still be most disappointing, as shown by the following figures:

Capital		£1,800,000
Working expenses	£25,000	
Maintenance	35,000	
	£60,000	
Amortisation to replace capital at end of 20 years	67,000	
		£127,000
Less earnings estimated on basis of one-half existing traffic	45,000	
Four per cent. guarantee	72,000	
		117,000
Leaving an actual loss to investors of		£10,000

And if the Pacific cable were duplicated, which I contend would be absolutely necessary to make it a successful competitor to the existing system, the loss would, of course, be immensely greater.

When writing to Sir Henry Holland the letter to which you refer, I was endeavouring to meet objections raised by opponents to the strong position which we had built up, and which had been described as a monopoly. As a matter of fact, our control of the Australian traffic has never depended on the possession of exclusive privileges, which alone would constitute a monopoly in the strict sense of the word, but it has been the result of good businesslike work carried out on strictly economical principles.

As to the strategic question, I can only express surprise that you should think a Pacific cable would be safer in time of war than the existing cables, which follow the principal trade routes, where British war-vessels would presumably be found in far greater force than in such a remote region as the Pacific Ocean.

The three alternative routes which I had in mind when referring to the *Globe* article were (1) the cables from England to Aden round the coast of Africa; (2) the Indo-European Company's system; (3) the Great Northern Company's system.

With the Indo-European and Great Northern Companies we have working agreements, and the first named route is, to a large extent, owned by the Eastern Company.

With regard to your last point, the only difference between the figures submitted to Lord Ripon and those given in my letter of the 30th ultimo is that in the one case the deficit includes 4 per cent. interest on capital, and in the other the deficit is shown without interest. But the practical result to an investor is precisely the same, and, with such figures before you, I would again ask whether you would be prepared to put your name to a prospectus inviting subscription from the public for such an unprofitable scheme.

Having now answered your letter the correspondence must cease, as your time and mine is much too valuable to be taken up with an academic discussion of this kind. If, however, the question should take a more definite shape, I shall be happy to resume the discussion with a view to arriving, if possible, at a practical result.—Yours faithfully, JOHN PENDER.

To the Honourable Sir Charles Tupper, Bart., G.C.M.G., C.B.

SIR CHARLES TUPPER TO SIR JOHN PENDER.

Office of the High Commissioner for Canada,
17, Victoria-street, London, S.W.,
June 8, 1894.

Dear Sir John Pender,—I am not surprised to find by your letter of the 6th inst. that you wish to close the correspondence which you initiated, and I cannot help thinking that those who have followed it will wonder why it was ever commenced. I am quite satisfied to leave all the questions at issue to the judgment of the public. Your admission that the "existing service" has already received over £2,000,000 of Government subsidies; that the life of a cable may fairly be estimated at 20 years; and that you are responsible for the statement that the existing service to Australasia is a "monopoly" is very satisfactory to me. I am also glad that I have been able to induce you again to revise your estimate. In reply to your question, I venture to suggest that capitalists will not be influenced in this matter by your opinion or mine, as their decision will depend upon the action of the Governments of the United Kingdom, Australasia, and Canada.—Yours faithfully, CHARLES TUPPER.

Sir John Pender, G.C.M.G., M.P.

KINGSTON-UPON-HULL ELECTRIC LIGHTING ACCOUNTS.

The accounts of the electric lighting department for the year ended October 31, 1894, have been issued. The capital expenditure during the year amounted to £6,212 and the total expenditure to December, 1894, has reached the sum of £39,031. Below is given the revenue account and general balance-sheet.

GENERAL BALANCE SHEET.

Liabilities.		£ s. d.
Net revenue account—balance at credit thereof December 31, 1893		13 2 4
Balance at credit thereof December 31, 1894		1,053 1 2
Amount due to treasurer—revenue account to December 31, 1894	£1,185 2 11	
Ditto, capital account, ditto	39,031 13 9	
		40,216 16 8
		£41,283 0 2

Assets.		£ s. d.
Capital account—amount expended for works		38,743 14 1
Stores on hand at December 31, 1894—coal £31. 2s.; oil, waste, etc., £17. 18s. 7d.; general, £287. 19s. 8d.		337 0 3
Sundry debtors for current supplied to December 31, 1894, £2,151. 19s.; other debtors, £50. 6s. 10d.		2,202 5 10
		£41,283 0 2

REVENUE ACCOUNT.

Dr. A.—To Generation of Electricity.		£ s. d.
Coal or other fuel, including dues, carriage, unloading, storing, and all expenses of placing the same on the works	£528 0 4	
Oil, waste, water, and engine-room stores	78 8 9	
Wages at generating station	424 9 2	
Repairs and maintenance as follows: buildings, £7. 12s. 3d.; engines and boilers, £92. 5s. 3d.; dynamos, exciters, transformers, motors, etc., 4s. 5d.; other machinery, instruments, and tools, £14. 14s. 10d.; accumulators and accessories, £15. 6s. 2d.	130 2 11	
		1,161 1 2
B.—To Distribution of Electricity.		
Wages and other remuneration to linesmen, fitters, labourers	81 12 1	
Repairs, maintenance, and renewals of mains of all classes, including materials and laying the same	59 1 4	
Repairs, maintenance, and renewals of transformers, meters, switches, fuses, and other apparatus on consumers' premises, together with cost of materials and lamps sold	5 3 4	
Repairs, maintenance, and renewals of apparatus at distributing stations	0 8 6

LEGAL INTELLIGENCE.

INCANDESCENT ELECTRIC LAMP COMPANY v. BRUSH ELECTRICAL ENGINEERING COMPANY.

This, case, which was an action for damages for breach of a covenant for quiet enjoyment, was heard last week before Mr. Justice Wright, without a jury.

Mr. Lawson Walton, Q.C., and Mr. Loehnis appeared for the plaintiffs, and Mr. Bigham, Q.C., and Mr. Tindal Atkinson for the defendants.

The plaintiffs are under-lessees of certain premises at Brook Green, Hammersmith, under a lease of September 20, 1893, from the defendants, containing the covenant for quiet enjoyment now sued on. The defendants were entitled, under a lease of February 21, 1889, from Mr. P. J. M'Manns, granted to the defendants by their then name of the Anglo-American Brush Electric Light Corporation, Limited. A portion of the land conveyed by these leases was and is used as a roadway by the Compressed Air Carpet and Tapestry Cleaning Company, who hold the adjoining premises under a lease from Mr. M'Manns, and there is no other approach to their works. On February 21, 1889, the defendants granted to Mr. M'Manns a right of way to the premises now occupied by the Carpet Cleaning Company for two years, or for such less period as he should reasonably require for obtaining another entrance into the said premises, and he agreed at the end of that time to block up the roadway. This agreement was subsequently extended till a certain private road, leading to the premises, should be taken over by the local authority. This had never happened ; no other entrance to the premises of the Carpet Cleaning Company was ever made, and damages were claimed for the continued use of the roadway by the latter. The plaintiffs claimed that the defendants ought to have compelled Mr. M'Manns to open another entrance and close up the roadway.

Mr. Justice Wright said that he regretted that he need not call on Mr. Bigham. Judgment would be for the defendants, with costs. This would not hinder the plaintiffs in any action they might bring for rescission of the contract, if they entered into the lease under the impression that the right of way was merely temporary. Stay of execution, pending appeal, was granted on the usual undertaking.

COMPANIES' MEETINGS AND REPORTS.

CAMBRIDGE ELECTRIC SUPPLY COMPANY, LIMITED.

The annual meeting was held at the Company's office, Thompson's-lane, on Wednesday last week, under the presidency of Mr. D. Munsey, chairman.

The **Chairman**, in moving the adoption of the report and accounts (which were published in our issue of the 22nd ult.), said that when the previous balance-sheet was sent out they had issued 2,275 shares, which gave them a capital of £22,200. Last year they issued 807 new shares, which added £6,456 to their capital. During the two months of this year they had had applications for 450 new shares, bringing in £3,600 capital. The debenture stock, which last year stood at £7,000, was now £4,000, while they also had a balance of £500 at the bank, so that practically they were £100 to the good. The interest on the debenture stock during the year had been reduced from 5 to 4 per cent. As there was only one other company paying so low as 4 per cent. on debenture stock, he thought they might be congratulated on the arrangements they had made. The amount owing to creditors in 1893 was £1,500, while at the end of last year it was £175, chiefly for current expenses during December. The numbers of consumers had increased from 176 to 260, the number of units sold was 44 per cent. more than in 1893, and this had only cost an extra 5 per cent. in the working expenses. The number of lamps had increased by 29 per cent. It was proposed to instal a small new machine which would not consume so much coal. They also proposed to have a new boiler. The directors were pleased to be able to recommend the payment of a dividend of 2½ per cent. The Chairman then moved the adoption of the report.

Mr. Sturton seconded the motion, at the same time criticising the balance-sheet.

A **Shareholder** asked if the directors proposed to have a reserve fund. He thought they ought to.

The **Chairman** said that matter had been before them, but as it was a new Company they felt that they need not do anything that year. He was almost certain that next year they would be able not only to declare a better dividend, but also to lay something by for a reserve fund.

The motion was then put to the meeting and adopted.

Mr. C. A. Parsons said that was the second year of the Company's work, and that he hoped as time went on it would pay a larger dividend. They had just turned the corner, and were now making good progress. He thought they were justified in declaring a dividend nearly equal to the earnings of the Company, as the machinery and works were new. He moved that a dividend at the rate of 2½ per cent. be paid.

Dr. Latham seconded, saying the Company was to be congratulated on the success which had attended it, and for the careful way in which matters had been supervised by the chairman.

The motion was carried unanimously.

Sir Benjamin Brown and Mr. D. Munsey, the retiring directors, were re-elected, and Mr. A. Rutter was re-elected auditor. The directors were voted the sum of £100 for the work of the past year, and a vote of thanks terminated the proceedings.

CHELSEA ELECTRICITY SUPPLY COMPANY, LIMITED.

The annual ordinary meeting was held on Tuesday at the central station, Draycott-place, Chelsea, Mr. J. J. Courtenay presiding.

The **Chairman**, in moving the adoption of the report, which was published in our last issue, stated that the satisfactory result of the year's working was partly due to a reduction on all the items of expenditure relating to the production of electricity, and partly to increased volume of business. Although they had had to pay a larger price per ton for coal (an average of 9 per cent. higher than in 1893), the coal used to produce each unit came out at a lower cost ; wages, stores, and maintenance were also less. The expenditure of £4,979 on mains was for extensions arising out of the increased demand. The mains laid were capable of taking a supply for a large number of lamps with little or no additional expenditure ; and as the erection of new buildings as leases fell in was likely to continue, they hoped for a larger return on the capital already spent. There was no question that an important element to be considered when estimating in any given residential district the probable annual increase of lamps was as to what was the amount of rebuilding actually in progress or in view ? No company had better prospects in this respect than the Chelsea, as in no part of the Metropolis were more important alterations and improvements in progress than in its district, while the houses were mostly wired when building. The capital expenditure per lamp (£2. 9s. 4d.) fixed was as low as that of any other company in the Metropolis. The premises at Cheyne-walk would be able to contain plant sufficient, when fully equipped, to supply the needs of 50,000 or 60,000 lamps.

The report, having been seconded, was adopted.

HOVE ELECTRIC LIGHT COMPANY, LIMITED.

Directors : Colonel A. J. Filgate, R.E. (chairman), Colonel H. Wood, C.B. (vice-chairman), Harold A. Hoare, Esq , Carleton F. Tufnell, Esq. Engineers : Messrs. Crompton and Co., Limited. Secretary : Francis R. Reeves, Esq.

Report of the directors to be presented to the shareholders at the annual general meeting to be held at the City Terminus Hotel, Cannon-street, E.C., on Tuesday, March 12, 1895.

The progress of the Company continues in every way satisfactory ; the supply of current to consumers has been carried on without a single hitch ; whilst the machinery, batteries, and mains supplied and laid by Messrs. Crompton and Co., Limited, have given perfect satisfaction to the Board during the whole year. The number of lamps attached to the Company's mains has increased from the equivalent of 6,915 8-c.p. lamps at the date of the last annual report to 16,473 at the present time, whilst the number of consumers has increased from 105 to 233 in the same period. The sale of current per meter, which realised £1,265. 18s. 10d. during 1893, shows an increase to £3,508. 6s. 9d. during 1894, while the result of the past year's working has been a profit of £1,243. 0s. 5d., as against £77. 5s. 8d. for the previous 12 months. After deducting £563. 17s. 11d. for interest accrued on loans and debentures, a net balance to the credit of revenue account remains of £679. 2s. 6d., as compared with a corresponding figure of £1. 2s. 8d. at close of 1893. In dealing with the £680. 5s. 2d. thus available for division, the directors propose to write off £73 from the suspense account, to declare a dividend for the year at the rate of 3 per cent. per annum upon the shares of the Company, absorbing £594. 10s. 2d., and to carry the balance, £12. 15s., forward. The debentures offered to the public in March last were readily subscribed, but the shares were not so taken, and in consequence further capital is now required to discharge the bankers' loan and to meet the liabilities to the contractors and the cost of the additional machinery which the directors foresee will be required to supply the demand for current next autumn. The directors therefore invite subscriptions from the shareholders for the remaining 3,498 shares at par upon the enclosed form of application. The list for these applications will remain open until the general meeting on March 12, after which, should any remain unalloted, the directors propose, in view of the established position of the Company, to offer them to the public at a premium. It is with regret that the directors announce that in consequence of the pressure of other business Mr. John Wilkes has felt obliged

Digitized by Google

to resign his seat on the Board. The directors do not propose to fill up the vacancy. Mr. Harold A. Hoare retires from the Board by rotation, and, being eligible, offers himself for re-election. Mr. Robert Payne, F.C.A., the auditor of the Company, also offers himself for re-election.

REVENUE ACCOUNT, YEAR ENDING DEC. 31, 1894.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Manchester.—The Manchester, Sheffield, and Lincolnshire Railway Company require tenders by the 19th inst. for the supply, among other stores, of telegraph materials, tools, and oil.

Brentford.—The Urban District Council require tenders by the 12th inst. for the supply and fixing of telephones and electric calls in connection with the fire brigade. Further particulars were given in our last issue.

Leicester.—The Watch Committee of the Corporation invite tenders by the 15th inst. for the supply of copper lamps and iron columns. Full particulars may be obtained by applying to the superintendent of lighting, Mr. John Tebb, Lamp Office, Town Hall.

Stowmarket.—The Urban District Council require by April 15 tenders for lighting the streets of Stowmarket from August 15 next to May 15, 1896, and also for lighting the post office clock. Particulars as to the number of lamps and time of lighting may be had of Mr. S. Prentice, clerk.

Bradford.—As will be seen by our advertisement columns, the Corporation require tenders by the 28th inst. for the construction and delivery of two steam dynamos for their electricity works. Specification may be had on application to Mr. Baynes, Electricity Department, Town Hall, Bradford, on payment of £1. 1s.

Llanelly.—The Borough District Council desire plans, designs, specifications, and estimates of cost for the supply and installation of electrical plant and machinery, including street lamps and laying down mains. Plans of the district can be obtained from Mr. George Watkeys, C.E, borough surveyor, Llanelly. The plans, etc., are to be sent to the clerk of the Council before the 25th inst. Details are given in our advertisement columns.

Eccles (Lancs.).—The Corporation desire by the 16th inst. tenders for an electric light installation at their sewage farm works, Peel Green-road, Patricroft. Specification of work required and all particulars may be obtained from the engineer, Mr. H. Leonard Hinnell, A.M.I.C.E. (Hinnell and Murphy), 15, Mawdsley-street, Bolton, on deposit of 10s., which will be returned on receipt of a *bonâ fide* tender. Tenders are to be sent to Mr. Geo. Wm. Bailey, town clerk, Town Hall, Eccles, addressed to the chairman of the Sewage Committee.

RESULTS OF TENDERS.

Tunbridge Wells.—The tender of Messrs. Strange and Sons, of Tunbridge Wells, has been accepted, at £140, for constructing three underground transformer stations for the Lighting Committee.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—The receipts for the past week were £3,073.

Commercial Cable Company.—This Company has declared a quarterly dividend of 1¾ per cent.

Great Northern Telegraph Company.—For the month of January the receipts were £21,200.

Wells.—A meeting of the Town Council is to be held on Monday to consider the question of gas *versus* electric light.

Blackpool.—The electric light is being installed in the Victoria Hotel, about 160 lamps being provided for all the principal rooms.

Eastern Telegraph Company.—The receipts during February were £62,342, as against £54,904 for the corresponding period of 1894.

St. George's, S.E.—The Vestry have disapproved of the construction of transformer-chambers in any of the thoroughfares of the parish.

Cuba Submarine Telegraph Company.—For the month of February the receipts were £361 more than for the corresponding period of 1894.

Ballymoney.—Several members of the Town Commissioners have suggested the adoption of the electric light or lighting the streets by oil lamps.

Direct Spanish Telegraph Company.—The receipts for the month of February were £1,690, as against £1,698 for the corresponding period of last year.

Eastern Extension Telegraph Company.—For the month of February the receipts show a decrease of £974 as compared with the corresponding period of 1894.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 3rd inst. amounted to £934, as compared with £635 in the corresponding week of last year.

Brazilian Submarine Telegraph Company.—The directors have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, tax free, for the quarter ended December 31.

City and South London Railway.—The receipts of the Company for the week ended March 3 were £953, against £934 for the corresponding week of 1894, or an increase of £19. The total receipts for the current period of the present half-year are £8,940, against £8,544 in the corresponding period of 1894, an increase of £396.

Digitized by Google

Hull.—The Electric Light Committee of the Corporation announce that there has been a profit of £1,000 upon the year's working of the electric light station. It has been resolved to reduce the price of current to consumers from 6½d. to 5½d. per unit.

Burton-on-Trent.—Alderman Lowe, in moving the adoption of the Gas and Electric Light Committee's report at a meeting of the Town Council on Wednesday, stated that the working of the electric light station during the past year had resulted in a loss of £1,802.

Sale of Business.—"Z. Y.," care of Messrs. Dawson's, 161, Cannon-street, E.C., having started a branch electrical business in a provincial city, and not having sufficient capital to carry it on and extend it properly, is desirous of meeting with a purchaser.

Huddersfield.—The Corporation are about to open a showroom for the purpose of exhibiting electrical appliances. Firms desiring to exhibit special apparatus or machinery may apply to Mr. A. B. Mountain, borough electrical engineer, St. Andrew's-road, Huddersfield.

Electro-Chemical Agency.—In the matter of the British Electro-Chemical Agency, Limited, a petition has been presented to the High Court of Justice (Chancery Division) for confirming a resolution of the above Company for reducing its capital from £75,000 to £50,000.

Hastings.—The Hastings and St. Leonards-on-Sea Electric Light Company have decided to devote their entire attention to the generation and distribution of electricity, and now invite tenders for the purchase of their installation business, with a useful stock of fittings, etc.

Kendal.—The Town Council, on the advice of the Gas and Water and Electric Light Committee, have resolved to oppose the application of the Windermere and District Electricity Supply Company for a provisional order under the Electric Lighting Acts, and to supply electrical energy themselves.

Redditch.—The Urban District Council, in regard to complaints as to the inadequate lighting of the town, have given instructions to the Public Works Committee to enquire into the existing lighting arrangements with a view to their improvement, and a deputation has also been appointed to confer with the directors of the gas company on the subject.

Brush Electrical Engineering Company.—The directors have declared an interim dividend for the six months ended December 31, 1894, at the rate of 6 per cent. per annum on the preference shares, and at the rate of 5 per cent. per annum upon the ordinary shares, payable on the 18th inst. The transfer-books of the Company will be closed until the 19th inst.

Maidstone.—The Urban District Council last week adopted the report of the Electric Lighting Committee, who stated that they had had an interview with Mr. Thomas King (manager to Mr. R. Dann), who was anxious to negotiate with the Council for a transfer of the order, and that he should be requested to send in full particulars of the scheme for consideration.

Electric Power in Mining Operations—Some new machinery is being put in the Robinson mine in South Africa. In addition, electric plant is being constructed for all the pumping plant, as well as for lighting purposes Moodies' electrical power installation having been completed, conductors have been laid to the United Ivy, Ivy Extension, and Agnes block.

Queenstown.—The Town Commissioners, having received a letter from the Queenstown Gas Company, in which it was stated that the directors could not see their way to giving a reduction in the price of gas per lamp, decided to adjourn the consideration of the letter to a special meeting, when it will be considered with a report on the proposed lighting of the town by electricity.

Wednesfield.—The Clerk to the Urban District Council mentioned to the latter last week that the Council might very well consider the question of having the electric light. He stated that there was plenty of engine power in Wednesfield, and it would, perhaps, be possible to rent that power and lay down plant. The suggestion does not appear to have met with any support.

Business Announcement.—The Unbreakable Pulley and Mill Gearing Company, Limited, of West Gorton, Manchester, inform us that they have appointed Messrs. McKenzies, Limited, of Camden Quay, Cork, and Messrs. J. P. Evans and Co., of Limerick, as their sole agents in those districts for the sale of their "Unbreakable" pulleys, adjustable swivel bearings, bright steel shafting, etc.

Sale of Plant.—"Solicitors," care of Gould's Advertising Offices, 54, New Oxford-street, W.C., have for disposal in Clerkenwell, as a going concern, plant and machinery, including a 9-h.p. gas-engine, 24 surfacing and polishing lathes, screw stamping-press, vices, forge, tools, chucks, circular saw benches, etc., together with office fittings. A lease of the workshop and house would be granted.

Messrs. Swinburne and Co., Limited.—Mr. Holt, late managing director, has been appointed general manager of this Company, with the control of their affairs as from January 1, 1895. The Company report that they are extremely busy at present, having more orders and enquiries than at any previous period. They have now opened a showroom at 66, Victoria-street, Westminster, where many of their specialities are on view.

Liverpool.—The Special Lighting Committee of the City Council met on Monday to consider the terms which the Electric Light Supply Company are prepared to accept from the Corporation for their undertaking. The negotiations have been in progress for several weeks, and the final stage was reached the other day, when the committee were informed as to the amount the company would probably take and the conditions under which the business could be acquired.

Bradford.—The Gas and Electricity Committee of the Town Council last week accepted tenders for the supply of 13,000 tons of cannel coal. A discussion also took place with regard to the proposed extension of the electricity works and the proposal to buy land in Valley-road for new works. It was eventually determined that a special meeting of the committee should be held, when the suggested site for new works will be visited and the proposals will be fully discussed.

Hampstead, N.W.—The Vestry last week adopted a report of the Lighting Committee to the effect that the remuneration of Mr. W. H. Preece, for preparation of plans and specifications, examination of tenders, and general supervision of the works already sanctioned by the Vestry, be 5 per cent. upon the outlay of such works. The committee also recommended that the remuneration of Mr. Preece for performing the above duties in connection with all future works which may be sanctioned by the Vestry be 4 per cent. on the outlay of such works. This proposal was, however, referred back for further consideration.

Burnley.—The Gas Committee of the Town Council recommended at a meeting of the latter this week that in future the charges for electricity be reduced from 6d. to 5d. per unit for lighting purposes, and 4d. to 3d. for other purposes. Alderman Collinge said the profit for last year on an income of £2,215 was over £100. They expected the reduction would create such an extra demand as to keep the profit as much as before. The reduction was agreed to, and it was decided to seek powers to borrow £3,000 for additional machinery at the electric lighting stations, and £2,500 for extensions of the mains.

Medical Electrical Institution, Limited.—This Company was before Mr. Justice North on Saturday on a motion for judgment in an action brought by debenture-holders. It appears that £2,890 worth of first debentures had been issued, which became due on the company becoming insolvent or a distress being issued. Both these events had happened, the landlord of the Company's premises having issued a distress for rent. A receiver had been appointed, and the distress paid out. This was a motion for judgment in default of defence. His lordship made the usual order, and directed the sale of the property.

Wigan.—The Tramways Committee of the Corporation have received a communication from the Sandycroft Foundry and Engine Works Company as to the new system of electric conduit for tramways. At the same meeting the town clerk submitted the draft agreement for lease of tramways to Platt Bridge. It was decided that, subject to the contractors and the tramways company giving a guarantee for the performance by the company of the conditions of the lease, the draft agreement be approved, and that the Finance Committee be recommended to raise £20,000 for the purpose of the tramways undertaking.

Bournemouth.—The electric light company announce a reduction of 1d. per unit—that is, from 8d. to 7d.—the reduction to commence after March 30; also to furnish to the consumer the "Wright" indicator, and with this in use, under certain conditions, the price per unit will be reduced to 5d. The sliding scale of discounts heretofore conceded and calculated upon the gross annual consumption will be abolished, and the "Wright" system applied to those consumers who may desire it, 5d. per Board of Trade unit being charged for all current consumed in excess of 300 hours' use per half-year of the maximum current taken as shown by a maximum demand indicator.

Edison and Swan United.—The directors have resolved to pay on account of the dividend of the current year at the rate of 5 per cent. per annum, less income tax, on the "A" shares of the Company for the half-year ended December 31, 1894. This will work out as follows: on the 89,261 ordinary shares, £3 paid, 1s. 6d. per share; on the 5,000 shares, £5 paid, allotted to the Edison Electric Light Company, Limited, 2s. 6d. per share; on the 12,139 shares, £5 paid, allotted to the Swan United Electric Light Company, Limited, 2s. 6d. per share; all less income tax. The payment will be made upon the register as it stood on the 5th inst., and the dividend warrants will be issued on the 20th idem.

Kingston-on-Thames.—As mentioned in our last issue, Major-General Crozier held an enquiry last week respecting the proposal of the Town Council to borrow £10,000 for an extension of electric lighting. There were present Councillor Collings (chairman of the Lighting Committee), the town clerk, the borough surveyor, Mr. Preece (the consulting electrical engineer), and Mr. J. Edgcome (borough electrical engineer). Councillor Collings stated that the Corporation installed the electric light in 1893, and it had since been in operation with steadily increasing success. It was soon found that with the great demands for current, it would be necessary to add to the plant and mains originally contemplated.

Dundee.—A new engine and dynamo have just been laid down at the central station. The engine is 200 h.p., and the dynamo is coupled direct. There are now seven engines and seven dynamos at the station. The number of consumers of the current continues to increase, and it is expected that further additions to the plant will have to be made before next winter. It was reported to the Gas Committee of the Town Council on Tuesday that frequent bursts had taken place in the iron pipes at the electric station, and it was recommended that brass pipes should be substituted at a cost of £40. 10s. The meeting recommended the Council to agree to the proposed substitution, and to accept the offer of Messrs. Whyte and Cooper.

Digitized by Google

Kensington, W.—The Works Committee reported to the Vestry last week that they had had before them a letter from the House-to-House Electric Light Supply Company asking the Vestry to approve of a plan submitted by them for the extension of their mains in Kensington High-street, Allen-street, and Abingdon-villas. The plan showed the construction of transformer-boxes under the public way, and the committee recommended that permission should be given for the works being proceeded with. The Vestry adopted a further report of the Works Committee recommending that permission be given for certain works to be carried out by the Notting Hill Company in Holland-park.

Islington, N.—The Vestry having considered a report from the electrical engineer (Mr. A. Gay), calling attention to the fact that electric lighting enterprise is being prejudiced by the explosions of gas occurring from time to time in conduits, and to the possible danger to life resulting from such explosions, recommends that a memorial be presented to the Board of Trade urging that steps should be taken by legislation or otherwise to obtain greater control over the gas companies as regards any escape of gas from their mains, and that a copy of such memorial should be forwarded to the other metropolitan vestries and district boards, and to the several metropolitan electric lighting authorities, with a request that they will make similar representations.

General Electric Tramways Company, Limited.—This Company has been registered with a capital of £50,000 in £1 shares. The object is to acquire tramways and tramway concessions for the construction of tramways or tramway plant, and to carry on business as tramway proprietors, electrical and mechanical engineers, and in particular to acquire certain interests in tramways at Hartlepool and West Hartlepool, county Durham. The signatories are Sir D. Ccoper, 6, De Vere-gardens, W.; Mr. J. W. Barclay, 54, Lansdowne-place, W.; Mr. P. E. Beachcroft, 10, Upper Hamilton-terrace, N.W.; Sir H. C. Mance, K.B., C.I.E., Manoro, Bedford; Mr. I. I. Courtenay, Temple, E.C.; Sir J. Pender, J.P., Rugby; and Mr. A. B. Blackburn, M.I.C.E., Bushbury Works, Wolverhampton.

South Westmoreland.—The Rural District Council have had an interview with Mr. Morse, who represented the Windermere Electricity Supply Company. Mr. Morse, in reply to the chairman, said he did not know that there were any special points in the application upon which he wished to make remarks. Two points had been raised when the application came before the Council, one of which he believed was that the area proposed by the company should be curtailed. The area had been marked as required by the Board of Trade, and he hoped it would meet with the approval of the Council. It would extend from Burton-in-Kendal on the south to a point indicated north of Kendal, and across in a westerly direction. All he asked was that the Council should approve of the application to the Board of Trade for the portion of the district defined. It was unanimously agreed to consent to the application.

Hobart Electric Tramway Company. — An extraordinary general meeting will be held at College-hill-chambers, College-hill, London, E.C., on Wednesday, the 13th inst., at 2 p.m., when the following resolution will be proposed: "That, inasmuch as the amounts of the £30,000 first mortgage debentures and the £15,000 second mortgage debentures issued by the Company are together equal to the nominal amount of the share capital of the Company issued, the directors be and they are hereby authorised, pursuant to Article 194 of the articles of association of the Company, to create and issue £5,000 further mortgage debentures ranking, *pari passu*, with the existing second mortgage debentures of the Company, or subject thereto, and to the first debentures of the Company as the directors think fit." A meeting of the holders of the second mortgage debentures of the Company will also be held on the 13th inst. at 2.20 p.m.

Leicester.—The Electric Lighting Sub-Committee of the Corporation had submitted to them on Friday by Mr. Colson, the gas and electrical engineer, his official report upon the explosion that occurred recently in the Market-street transformer-chamber near the Granville Hotel. Mr. Colson, who made an inspection of the chamber within a few minutes of the accident, states that in his judgment the explosion was caused by an electric arc being formed between the terminals in the high-pressure junction-box, and the consequent gasifying of the oil used in the box as the insulating medium. Owing to the explosion it has been decided to substitute specially prepared wax for the oil at present in use in the various transformer-chambers in the town. Mr. Colson is confident that coal gas had nothing whatever to do with the explosion. The Board of Guardians have decided to again invite tenders for fixing up a telephone.

Cheltenham.—The Electric Lighting Committee of the Town Council have had presented to them the monthly report of the borough engineer. The further consideration of suggested extension of the mains was adjourned. The committee had considered a resolution of the Public Library Committee stating that an error had been made in estimating £57. 18s. as the cost of the gas supply for the past year, the average cost for four years having been only £41. 16s. 6d., and that under these circumstances only £40 could be paid for the electric light. It was resolved to accept the offer of the Library Committee, subject to the installation being to the satisfaction and under the control and superintendence of the electrical engineer. Mr. Norman, chairman of the Electric Lighting Committee, has no doubt that during the ensuing month the electric light will be turned on by the contractors, who will run the station on their own responsibility for four weeks. By the middle of April the station will be in the possession of the Corporation.

Bangor.—Acting upon a suggestion made by an inspector of the Local Government Board, the Water and Gas Committee of the Town Council recommended on Wednesday that the borrowing powers of the Council be increased by £10,000 instead of £2,500, a large proportion of which is required for gas purposes. Dr. Grey Edwards asked whether the time had not come when the Council should consider the advisability of spending the money in question upon electric lighting. He was afraid that if £10,000 was now secured for improving the gasworks, electric lighting at Bangor would be thrown back a generation. He moved that the Water and Gas Committee be instructed to report upon the expediency and cost of providing electric lighting before proceeding to expend any large amount on the gasworks, and report to the next meeting. Mr. Robert Hughes seconded the motion. Both the recommendation of the committee and the resolution proposed by Dr. Edwards were adopted.

The Rhondda.—The Urban District Council for Ystradyfodwg received on Friday a deputation from the Rhondda Valley Chamber of Trade with reference to the proposal to light the public buildings and the streets of the Rhondda with electric light. One of the deputation complained that they were being very badly treated by the Ystrad Gas and Water Company. Another of the deputation said the Chamber had decided to offer a premium of £50 for a scheme to light the valley with electricity, but as the Council had taken the matter up they thought it advisable to approach them before taking any steps. If the scheme was carried out to a successful issue to light the streets, the deputation asked if the Council would also supply the business houses with electric light, as they now had to pay 4s. 3d. per 1,000ft. for gas of a poor quality. The Chairman (Mr. W. Jenkin, J.P.) assured the deputation that the Council were still continuing their investigation into the matter, and that they might rely upon the Board making every effort to supply them with the light if the scheme was successful.

Mersey Railway.—It was stated by the chairman at a meeting on Wednesday of the Mersey Railway Company that in the annual report it was mentioned that the subject of working the railway by electricity was still receiving the consideration of the directors, and "that they hoped by the date of the annual meeting to report further on the matter." From letters which he had received it was evident that there was a wide-spread belief that the directors had absolutely determined to employ electricity as a means of motive power, but that was not so. Some members of the Board were very strongly in favour of it, and they had been making exhaustive enquiries as to the probable outlay and the probable results. They had that day received a report from two eminent engineers upon the matter. Personally he was neither in favour of it nor against it. If it could be shown to him that the working expenses could be materially lessened by electricity, then he might consider it wise to adopt it, but until that was made clear he should not recommend the shareholders to enter upon experiments of so extensive a character.

Lighting of Printing Works.—The new printing works of the Geraldine Press, 21, Whitefriars-street, E.C., and the block of offices belonging to *Answers*, Limited, in Tudor-street, E.C., are now lighted throughout by electricity. Mr. E. R. Dolby, A.M.I.C.E., of 8, Princes-street, Westminster, acted as consulting engineer for the proprietors. The current is produced in the basement of the works of the Geraldine Press by a compound-wound direct-current dynamo, made by Messrs. Crompton and Co, and driven direct by an engine made by Messrs. Belliss and Co., of Birmingham. About 190 lamps have been installed in the works and about 80 lamps in Tudor-street, and the lighting of both premises is controlled from one switchboard fixed close to the dynamo. The large Hoe machine used for printing *Answers* and the Marinoni machines used for printing the other papers published at the same offices are lighted up internally by incandescent lamps, which much facilitate the work. The wiring of the buildings was carried out by the Electrical and General Engineering Company, of 86, Leadenhall-street, E.C., under the supervision of the consulting engineer.

Bath.—Major Cardew held an enquiry on Wednesday into the applications for provisional orders under the Electric Lighting Acts. The original applicants were the electric lighting company, for whom Mr. Morse appeared, with Sir Frederick Bramwell as an expert witness. The local authority would not consent to the application, and made a competitive one, being represented by Mr. MacMorran and Mr. W. A. Jolly. The case of the company was first heard. It was explained that the electric light was introduced in Bath by Mr. Massingham in 1890, who had a license which would expire at the end of 1897. In 1891 Mr. Massingham transferred the business to the company which now sought the order, with power to light the whole city instead of a restricted area. It was said that £40,000 had been spent in the undertaking, and that £15,000 would provide for the contemplated development. Sir Frederick Bramwell was examined as to the suitability of the town weirs and the destructor for generating purposes, as the Corporation contemplate using them, and gave it as his opinion that they are valueless. For the authority it was stated that they were dissatisfied with the company's supply, and wished to have the control of the light in their own hands.

The City.—At a meeting of the City Commission of Sewers on Tuesday, Mr. Berridge, in answer to Mr. Wallace, said that no report had been presented by his committee on the subject of the use of telephone tubes because some delay had occurred on the question as to the legality of the Commission taking any part of the rental of the telephone tubes, and counsel's opinion was now being taken. When that was received the committee would probably bring up a report. Mr. C. T. Harris said that was

Digitized by Google

exactly what he had predicted. He did not think the Commission had any right to take a rental. The Chairman wished to draw the attention of the Court to a report by Major Cardew on the subject of explosions in transformer stations. That gentleman had explained that the explosions were caused by a deposit of sodium, and that the metal sodium came in contact with the wet and caused an explosion. He wished to ask the electrical inspector whether he had had any experience of that kind in the boxes in the City. Inspector Voysey said with regard to the sodium found in the boxes in St. Pancras it had been formed by the current passing through the bare metal conductors resting on the insulators. In the City, however, there were no bare metal conductors or stoneware insulators.

Aberdeen.—The Gas and Electric Lighting Committee of the Town Council have recommended the acceptance of the offer of Messrs. Scott and Sellar, of Aberdeen, to extend the distributing mains and erect the portion of the engine block at the electric lighting station in the same manner and at the same rates as in their original contract. Sir George Trevelyan has sanctioned the raising by the Town Council of £5,000 for the execution of works under the Aberdeen Electric Lighting Order, 1890, being the balance of the loan of £25,000 sanctioned by the Council in 1893. The Town Council have decided, consequent upon the appointment of a Parliamentary Committee with reference to the question of the control of the telephone system, to join with other corporations in giving evidence on this question before the committee. For the appointment of electrical engineer, the Electric Lighting Committee recommended, a few days ago, the names of Messrs. A. S. Blackman, Aberdeen; John Christie, Londonderry; W. H. Tittensor, Dundee; and John Williamson, London. Mr. Johnston, convener of the committee, proposed Mr. A. S. Blackman for the appointment, who, he said, was in the service in the meantime, and he might say that Mr. Blackman had given the utmost satisfaction. Bailie Mearns seconded, and, on a division, Mr. Blackman was declared elected.

Tunbridge Wells.—The question of providing the Town Hall with the electric light came up for consideration at a meeting of the Town Council on Wednesday. It was said that £300 would be needed for the purpose, and to this outlay on the municipal buildings several members objected. The Mayor, speaking from his own experience, suggested that the matter of the Town Hall installation should not be hurried. First of all, let the Council develop the electric light as much as possible, and so get a source of income from the public. They themselves could afford to wait. He should suggest that the Council-chamber part of the Town Hall be not fitted up with the electric light, as it was not needed there. Councillor Wilmott said the argument worked two ways. When they said "supply the town with the new light as much as possible, but don't put it in the Town Hall," it seemed like the doctors who recommended medicine they themselves would not take. Councillor Wilmott quite agreed that they need not spend so large a sum as £300 on the Town Hall, but suggested a lesser sum as an experiment to show town customers that the Corporation could themselves use the class of light they recommended. The recommendations of the Lighting Committee were in part endorsed, but another report fully dealing with the details of the new lighting proposals as regards the municipal buildings is to be laid before the Council at a future meeting, and before any sum is voted for the purpose.

Electric Traction.—The chairman of the Barcelona Tramways Company mentioned to the shareholders at a meeting on Wednesday that there was a paragraph in the report of very great importance. It was as follows: "Your directors having become aware of the advantages, both to the companies and to the public, to be derived from the substitution of electric for animal traction are taking steps towards obtaining powers to adopt it, and during the interval which must inevitably intervene before finally obtaining the necessary permission they are diligently enquiring into the respective merits of the various systems now in use." He said that they would observe that that paragraph was carefully worded. They had studied with great attention the electric system; they had seen it at work abroad, and were convinced that the adoption of it would be of great advantage. At the same time, before actually embarking on that they must take care that the conditions under which they worked would not be made in any way onerous to them. They had one or, rather, two conditions which were sources of satisfaction as far as that company was concerned. First, they had an immense area to work upon—between 17 and 18 miles—and if they could save a large percentage in the working expenses, they were safe in adopting the system. The second consideration was that, as their fares were most moderate, there was little danger that they should suffer by being obliged to reduce them, assuming that they were able to work with better advantages.

Brighton.—The Town Council had before them yesterday the statement of accounts of the Corporation electric lighting undertaking for the year 1894. The capital invested in this undertaking is now over £120,000. The total receipts on revenue account for 1894 were £16,378, and the expenditure £6,490, leaving a balance (after providing for bad debts) of £9,800 gross profit. Against this and a balance of £300 brought forward from the last account have to be charged the interest on the redeemable stock debt, and the appropriations for the sinking fund, amounting together to £5,014, leaving a balance of £5,086 for net profit. Out of this the committee propose to make the payments for adjustment of old accounts, to set aside £3,000 to a reserve fund, and pay over £1,120 in aid of the rates. A report from Mr. Wright, the engineer of the electricity works, gives valuable information as to the working cost of the electric light station. He once more points out the importance of encouraging consumers to use electricity at times when the demand is not at its heaviest, as during those hours the costly plant is lying comparatively idle. It was with the view of affording such an inducement that the sliding scale, charging 7d. per unit for an average of two hours' working per lamp per day, and 3½d. per unit beyond that average was fixed. The committee now propose to give further encouragement in the same direction by making the lower charge 3d. per unit instead of 3½d., and to make the limit of the 7d. charge an average of one hour, instead of two, per lamp per day. They also recommend that the meter rent be reduced from 5s. to 2s. 6d. per quarter. Mr. Wright suggests that all meter rents should be abolished except to customers using less than one hour's light per lamp per day. The committee propose to recognise Mr. Wright's services in connection with the undertaking by offering him an increase of salary, from £400 to £600.

Leeds Tramways.—The Corporation Tramways Bill came before the Standing Orders Committee of the House of Lords on Thursday on the question of whether the standing orders should be dispensed with. There were present the Mayor and Town Clerk of Leeds, Alderman Ward, Alderman Firth, Councillor Battle, Councillor Wilson, and Mr. Hewson, city engineer. Mr. Hewson produced plans of the proposed generating stations, and explained them to the committee. The committee decided to dispense with the standing orders as regards the revival of powers for the construction of tramways, but declined to do so as regards the generating stations, the chairman observing that no doubt there might be found some means of getting round the question. After the promoters had left the House, Lord Morley sent a messenger to the office of the parliamentary agents with a request to see Mr. Pritchard. On that gentleman attending, his Lordship informed him that he had reconsidered the matter, and that, considering the importance of fixing the generating stations, he would allow an amended clause fixing the stations as they appeared upon the plan submitted by the city engineer. That being so, the Bill will now be reported as having complied with the standing orders. The only point now remaining for settlement has reference to granting power to the Corporation to work the tramways. At a meeting of the Town Council on Wednesday, Alderman Spark said the Corporation, according to the Bill, were asking for power to produce electricity. It seemed to him that if they got such power it would not be competent for the Council to discuss the question of haulage. Mr. Battle replied that the power was permissive, and not obligatory. The whole question of haulage must be discussed by the Council, but it would have been foolish when they were going for powers not to have asked sanction for electrical haulage. The Town Clerk confirmed what Mr. Battle had stated. There would, he said, be no obligation resting upon the Corporation to put down an electric power station in the event of parliamentary consent being given. The power had been asked for in order to comply with the standing order, which said that certain things, including the use of electric power, should not be used without consent. The Council would not be prejudiced in the least as between electric and cable haulage by powers being received to put down an electric power station.

Monmouth.—A special meeting of the Town Council was held last Friday to meet Mr. Harris, of Messrs. Bramwell and Harris, the engineers for the electric lighting part of the Corporation's combined drainage and electric lighting scheme, and Mr. Lailey, the engineer for the drainage section of the scheme. Major Lister, the Duke of Beaufort's agent, was present. The Mayor, Mr. W. Honeyfield, who presided, observed that it was a special meeting called to consult with the engineers on the completion of their plans for the combined drainage and electric lighting scheme. Before, however, they went into that matter, Major Lister was present and would answer any questions they would like to ask with reference to the proposed site for works on the Monnow at the Forge. If the Corporation would consider that matter first, they would then be able to set Major Lister at liberty. The Mayor, addressing Major Lister, asked whether in the event of the Corporation wanting water power at the Old Forge, he was prepared to let the Corporation have a 99 years' lease. Major Lister replied that on the terms of £50 for the use of water power, he would be prepared to grant the Corporation a 99 years' lease. The extent of the site was then considered by means of the plans, and after some conversation with the Mayor and members, Major Lister withdrew. The Council then resolved itself into committee to consider the scheme, as it had developed, with the engineers. The Town Council on Monday considered the plans for a combined scheme for drainage and electric light, prepared by Messrs. Bramwell and Harris, C.E., and Mr. Lailey, C.E., London. The Council discussed the plans in conjunction with the engineers in committee on February 22, and an addition of about £4,000 to the cost of the scheme was proposed, owing to additional details in the drainage of the streets of the town (Mr. Lailey's portion of the work), which would raise the original estimated cost of £18,000 to £22,000. Mr. Cossens proposed that that portion of the scheme which related to the electric light be relinquished, and that the Local Government Board be approached again for permission to drain into the Wye by gravitation. This was seconded and supported by several members. Mr. W. C. A. Williams intimated that the law would not permit the pollution of the Wye. The Mayor stated that they would effect a saving of 5d. in the £ to the rates by the earnings of the electric light. He showed that drainage alone would cost about 1s. in the £ for the next 30 years, whereas the combined scheme would reduce that sum to 7d., and at the end of the 30 years the Corporation would have plant producing about £600 per annum to be devoted

Digitized by Google

to the reduction of the rates. Messrs. Bramwell and Harris had now offered to take over that part of the scheme entrusted to Mr. Lailey and carry out the whole work at the original cost of £18,000. Mr. Cossens withdrew his proposition, and it was decided to accept the plans of Messrs. Bramwell and Harris.

Worcester.—The question of "extras" has come before the Electricity Committee of the Corporation. It appears that the committee have passed a resolution that the city engineer should be instructed not to sign any further certificates or other documents in connection with Mr. Rowbotham's contract for the electricity generating station. The committee have presented a detailed report by the sub-committee upon the "extras" payable, amounting to upwards of £4,400. Since investigating the above the committee have received another claim from the contractor for £1,068 for damages to his works through flood. The City Council a few days ago discussed the question of the £5,000 extras in connection with the electric light works. Mr. Williamson (chairman of the committee) said that the first thing which struck the committee was the systematic way in which the estimates had been wrong from beginning to end. He called particular attention to the charge of £1,450 for carting soil at the works beyond the 100 yards boundary, and added that the committee were not aware of the extra work being carried out. It appeared that the Corporation would have to pay for the work because the quantity surveyor had measured it and the surveyor had certified it. The surveyor had directed work without consulting the committee. He moved the adoption of the committee's report. Mr. Millington, who seconded, said that the original estimate for the electricity scheme in 1892 was £29,000, and now the expenditure was nearly £60,000. The Sheriff (Mr. Mathews) raised the question as to the Council's liability to pay the money. He said he thought under the terms of the specification that the contractor should have the written instruction of the engineer before undertaking extra work, and it appeared there was no written instruction. He therefore moved that the matter be referred back to the committee for reconsideration. Mr. Cook seconded. In answer to a member, the Town Clerk said that if the Council were going to fight the question it was not advisable that he should express any opinion as to the liability of the Council. Several members urged that the amendment should not be then put, as it would prevent any further debate, and up to that stage only one side had been heard. The amendment was, however, submitted, and carried by 21 votes to 15. The chairman of the County Council, in submitting to the latter last week a statement of the facts in connection with the contract for the installation of the electric light at the Shire Hall, explained that he went through and settled the draft contracts, which after some negotiations were agreed to by the parties. A contract with Messrs. Verity and Son for £91. 3s. 11d. was sealed at the last meeting, and that with the New British Electric Installation Contractors for £474. 6s. 6d. now came before the Council for an order for sealing. The report was adopted, and it was agreed that the opinion of an electrical expert as to whether the fittings, etc., had been properly carried out, should be taken before anything further was done in the matter.

Derby.—The Electric Lighting Committee of the Town Council have reported that they have had presented to them the accounts of Messrs. Siemens Bros., certified by the engineers, Messrs. Bramwell and Harris. The expenditure granted was £35,000. The committee have actually expended £34,000, and have incurred liabilities amounting to £9,000, making a total of £43,000, being £8,000 in excess of the amount granted. Messrs. Bramwell and Harris have made reports to the committee accounting for this extra expenditure, from which the following are extracts:—"Contract No. 1: Boilers.—Let to Messrs. G. Fletcher and Co., of Derby. The amount of this contract was £1,960; actual amount paid, £2,171, the excess being £211, which is accounted for by additions to coal elevator, stores, and renewals of parts of mechanical stokers, interest, extra chequer plates, and manhole cover, etc. Contract No. 2: For machinery.—Let to Messrs. Siemens Bros. and Co., Limited. The amount of this contract was £13,119; actual amount paid, £13,574, the excess being £450, which is accounted for by the purchase of spare gear, fire insurance, extra gearing, and safety precaution on switchboard required by the Board of Trade. Contract No. 3: Building Station, etc.—Let to Mr. Hy. Vernon, of Derby. Amount of contract, £6,464; actual amount paid, £6,868, the excess being £400. The excess is accounted for by fire insurance premiums, interest on retention money, covering the mill race adjoining engine-house, and small extras which arose during the contract, including laying extra depth of concrete in foundations. Contract No. 4: Mains.—Let to Messrs. Siemens Bros. Attention should be directed to the fact that this contract is for materials supplied and work done on a schedule of prices, and not for a lump sum. It is in this contract that the largest increased expenditure occurs, which cannot be regarded as 'extra,' inasmuch as it is for work and materials beyond what was originally contemplated." A table is appended to the report illustrating the increase in this contract. When the original estimate was prepared, it was contemplated that a period of two years would elapse from the date of opening before the largest output would be realised, but, as a matter of fact, this period arrived at the end of 15 months. From this table it appears that the greater portion of the extra expenditure was owing to the abnormally rapid and unexpected increase of the rate at which the public has taken the light, and the original estimate provided for a station with a capacity of 7,500 8-c.p. lamps for private lighting, and 45 public arc lamps lighting 2¼ miles length of streets, whereas the actual capacity of the station now is 15,000 8-c.p. lamps, and 77 public arc lamps lighting 4½ miles of streets. The following expenditure has been incurred irrespective of the above-named contracts: covering steam-pipes, £134. 11s. 8d.; meters, etc., £556. 11s. 8d. There are at present 10,012 lamps on the private supply, and a further 2,000 are ready to be connected. By October next (the end of the two years originally contemplated) the total present capacity of the station will be absorbed. In addition to the above analysis, the committee have personally gone through the accounts of Messrs. Siemens on Contract No. 4, and give the items which make up the extra expenditure, £7,868. Messrs. Bramwell and Harris have also advised the further expenditure of £5,000, made up as under: alteration of premises adjoining station, £1,000; additional distributing and connecting mains, £2,000; three additional boilers, £2,000. This question has been considered by the committee, and a resolution has been passed recommending the Council to incur this additional expenditure. The committee asked the Council at their meeting on Wednesday to approve the expenditure of £8,000 over and above the amount already voted, and also to vote a further sum of £5,000 as above stated, the money to be borrowed with the sanction of the Local Government Board. The expenditure was sanctioned.

Birmingham.—The City Council on Tuesday had brought before them by Mr. Martineau a motion, which was referred to in our last issue, that the Technical School Committee be authorised to expend £6,080 in providing electric light fittings and motive power at the new technical school, and that the Finance Committee be instructed to borrow that amount. He said they found there was an increasing use of electric motors as a power. With the application of electricity for power, it was also found convenient to have it for lighting as well. That was effected by having the machinery larger, which would conduce to the efficiency of the lighting and to the economy of the power. Thus, while it appeared from the figures that incandescent gas was a little lower in price, they recommended the adoption of electricity, because it would be more convenient, and the installation of the electrical plant on their own premises would be one of the best possible means for a practical education in the science of electricity. Alderman Kenrick, M.P., seconded. Alderman Pollack said he did not oppose the motion, and recognised the fairness of the report, but he differed from the committee as to the conclusions to be deduced from the figures. Mr. Bradley moved an amendment similar in terms to the one he moved at the last meeting of the Council—viz., "That with regard to the proposed electrical installation, the committee be instructed to accept the lowest tender submitted on the specification originally issued to a selected number of firms." He said he thought the committee had scarcely acted justly or wisely in the course they had adopted, and the importance of the principle which was at stake was much greater even than a slight difference between the tender now recommended for acceptance by the committee and the lowest tender received under the original specifications. He was afraid that if the Council sanctioned the course of procedure adopted by the committee the Corporation would sustain serious injury in finding firms of any standing and repute very reluctant to submit tenders to them. Messrs. Fowler and Lancaster tendered to do the work for £6,271, and then in November they saw a paragraph in the papers that a sub-committee of the Technical School Committee would recommend that the contract be given to another firm, outside Birmingham, at a higher price. He had letters from Dr. Hopkinson, who designed the Manchester Town Hall lighting, and from Mr. Preece, the Post Office engineer, speaking to the qualifications of Messrs. Fowler and Lancaster to carry out the contract. But the mind of the committee evidently was to pay more than was needful to take Birmingham work out of the town. Having rejected the tender in question, the committee threw over altogether the tenders received from the selected firms, and threw the contract open for general competition, the specifications being revised for this purpose. Supposing that revision was necessary, and not merely specious, should the specifications not have been submitted in their revised form to the firms who had originally tendered, and not to the whole kingdom? He maintained that they should, and that the course adopted was unjust to the firms first selected. Mr. Bishop seconded the amendment. Mr. Martineau said the whole of the firms which tendered under the first specifications also tendered under the revised specifications. The committee most carefully investigated the whole matter, and they saw reasons which to them were absolutely unimpeachable for the recommendation with which they now came before the Council. A division was then taken, Mr. Martineau intimating that the committee would regard it as a vote of confidence. The voting was 30 for the amendment and 28 against. Mr. Martineau said that he was going to say before, when he was not allowed to proceed, that circumstances had come to the knowledge of the committee which they could not state to the Council. If the confidence of the Council was not placed in them sufficiently to believe that they had reason for the course they had taken, they wished the Council to place the functions entrusted to them in other hands, and forthwith the committee would unanimously resign. A show of hands was taken upon the amendment as a substantive resolution, but there being a general demand for names, the latter were taken. At the conclusion of the voting, the Mayor said as a substantive motion, there were 32 for and 34 against. Alderman Clayton said that the Council decided that they preferred the amendment to the resolution, but that they would not confirm the amendment when it was put as a resolution. The resolution of the committee was dead with the first vote, therefore they must go to the next business. The Town Clerk endorsed what Alderman Clayton said. So far as concerned the resolution before the Council with reference to the electric lighting, the proceedings were at an end. The original proposition had not been carried; the amendment had been carried, but

Digitized by Google

not carried as a substantive resolution, therefore the whole matter was at an end so far as that resolution was concerned. It was open for the chairman of the committee to proceed with the rest of the business. Mr. Martineau then submitted resolutions recommending the purchase of apparatus and appliances for the technical school at a cost of £4,000, and the expenditure of £3,340 for architects' fees, electrical engineers' commission, and clerk of the works' salary in connection with the school, and concluded by moving the approval of the report, with the exception of that part connected with the electric lighting. Mr. Hughes seconded the resolution, which was agreed to.

PROVISIONAL PATENTS, 1895.

FEBRUARY 25.

4019. **An improvement in electric apparatus for engine-room signalling and like purposes.** Sidney Marow Eardley-Wilmot, Walter Thomas Wright Thackeray, Sydney Hoare, and Keith Ronald Mackenzie, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

4038. **Improvements in or relating to telegraphic apparatus, applicable for use in ships or other purposes.** James Bain Irvine and George Foulkes, 6, Lord-street, Liverpool.

FEBRUARY 26.

4065. **Improvements in electric tramways and apparatus connected therewith.** Sebastian Ziani de Ferranti, 27, Charterhouse-square, London.

4085. **A device for switching off the current from an incandescent electric lamp by a movement of the lamp itself, without its removal from the holder.** Wilford Wyatt Martin, Worcester Cross, Kidderminster.

4106. **Dynamo-electric generators and motors.** Arthur Edwin Lones, High-street, Princes End, near Tipton, Staffs. (Complete specification.)

4111. **Improvements in electric insulators.** George F. Chutter, Constitution-hill, Birmingham.

4119. **Improvements in electric contact strips.** Charles Méray-Horvath, 70, Market-street, Manchester. (Complete specification.)

4120. **Electric heaters for applying artificial heat to the human body and also for the purpose of artificially heating apartments, cars, furniture, and such like.** John Emory Meek, 70, Wellington-street, Glasgow. (Complete specification.)

4153. **Method of and apparatus for insulating electrical conductors.** James Yate Johnson, 47, Lincoln's-inn-fields, London. (Louis Welton Downes, United States.) (Complete specification.)

4154. **Improvements in apparatus for use in electro-deposition.** The Cowper-Coles Galvanising Syndicate, Limited, and Sherard Osborn Cowper-Coles, 47, Lincoln's-inn-fields, London..

4160. **Improvements in electric transformers or converters.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Thomson Electric Welding Company, United States.) (Complete specification.)

FEBRUARY 27.

4182. **Improvements in electrical furnaces and in regulating and working the same.** David Urquhart and Frank Wynne, 17, Victoria street, Westminster.

4215. **Improvements in electricity meters.** Hermann Herberts, 89, Chancery-lane, London.

4245. **Improvements in electrical galvanic batteries.** Giambattista Laura, 65, Chancery-lane, London. (Complete specification.)

4255. **A rheotone or novel apparatus whereby a battery of great internal resistance is rendered capable of generating an induction current in coils of low internal resistance.** Giambattista Laura, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

4257. **Improvements in or connected with electric arc lamps.** William Phillips Thompson, 6, Lord-street, Liverpool. (Wilhelm August Rasmus Mathiesen, Germany.) (Complete specification.)

4260. **Improvements in electric apparatus for indicating or recording at a distance the position or motion of a primary mechanism.** Alphons Custodis, 433, Strand, London. (Complete specification.)

FEBRUARY 28.

4303. **Electric signalling arrangement for locks and the like.** Hugo Nöhmer, 10, Friedrichstrasse, Berlin.

4323. **Improvements in cases for accumulator batteries.** Walter Claude Johnson, 28, Southampton-buildings, Chancery-lane, London.

4330. **Improvements in electric arc lamps.** James Yate Johnson, 47, Lincoln's-inn-fields, London. (Suddeutscher Rödrendampfkesselbau Simonis and Lang, Germany.)

4352. **Improvements in dynamo-electric machines and motors.** Llewellyn Birchall Atkinson, 1, Queen Victoria-street, London.

4357. **An improved electrical apparatus for reproducing images of distant objects.** Robert Berglund, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.)

MARCH 1.

4426. **Improvements in incandescent electric lamps.** Julius Wende, 70, Chancery-lane, London.

MARCH 2.

4458. **Improvements in or relating to apparatus for electrically steering ships.** Frederick Adolphus Langen, 3, St. Nicholas-buildings, Newcastle-on-Tyne. (Complete specification.)

4490. **Improvements in dynamo-electrical machines.** Sebastian Ziani de Ferranti, 27, Charterhouse-square, London.

4497. **Automatic current-permutating device for electro-magnets.** Oscar von Morstein, 89, Chancery-lane, London. (Complete specification.)

4499. **Improvements in or relating to electric indicating apparatus.** Richard Myers, 323, High Holborn, London.

4525. **Improvements in electrically-operated stringed musical instruments.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (William S. Reed, United States.)

SPECIFICATIONS PUBLISHED.

1894.

207. **Electrical transformers.** De Ferranti.

2437. **Electric time alarm and synchronising apparatus.** Cardoso e Bastos.

6888. **Telegraphic and telephonic apparatus.** Imray. (Société Anonyme pour la transmission de la force par l'Électricité.)

7054. **Electrically-propelled vehicles.** Clubbe and Southey.

7853. **Electro-deposition of metals.** Thoms and Burgum.

18480. **Electrical gaslighters.** Jaskey and Else.

20330. **Electromagnetic motor.** Vago.

24564. **Electro-locomotives.** Heys. (Heilmann.)

24583. **Electric car heaters.** Whittingham.

1895.

348. **Electric current rectifiers.** Close.

497. **Electric railways.** Love.

NOTES.

Society of Arts.—On Monday next, at 8 p.m., the first Cantor lecture on "Commercial Fibres" will be delivered by Dr. D. Morris, C.M.G.

Fire.—A telegram from New York states that the establishment of Mr. Nikola Tesla in that city was destroyed by fire on Wednesday morning. The damage is estimated at £20,000.

Institution of Civil Engineers.—If time permits, a paper by Mr. Henry Davey, M.I.C.E., on "Steam-Engine Economy: Condensing Engines," will be read at the meeting on Tuesday next.

British Association.—Sir Joseph Lister, Bart., foreign secretary of the Royal Society, will be nominated president of the British Association for the meeting which will be held at Liverpool in 1896.

Legislation in India.—It is stated that the Bill which provides for the electric lighting of the streets in Calcutta, Madras, Bombay, and Rangoon, will not be passed through the Council until the close of the present year.

James Forrest Lecture. — The James Forrest lecture of the Institution of Civil Engineers will be delivered, on May 2, by Prof. W. C. Unwin, F.R.S., M.I.C.E., and is intended to be a complete monograph on the history of experimental study of heat-engines.

Telephone Posts.—A correspondent asks an evening paper whether the National Telephone Company can show written permission for the erection of one post in 50, and whether the Postmaster-General will be advised to purchase without legal evidence of their right in regard to each post.

Cambridge University Local Examinations.—The exhibition of £30 per annum with a sizarship, offered by St. John's College, Cambridge, to the senior candidate standing first in pure and applied mathematics, has been gained by Mr. E. L. Watkin, Wellingborough Grammar School.

Railway Bills.—The House of Commons Committee of Selection have appointed a committee, Sir R. Paget, chairman, to meet on Wednesday next for consideration of the City and South London Railway; London, Walthamstow, and Epping Forest Railway; and Latimer-road and Acton Railway Bills.

Electrical Engineering in Europe.—The views of Mr. H. Ward Leonard, who recently visited this country, are set forth in a paper entitled, "Notes on Recent Electrical Engineering Developments in France and England," presented at a meeting of the American Institute of Electrical Engineers.

Duty Payable on the Unknown. — A *Times* correspondent states that the Canadian Customs Department has decided that electricity generated on the American side of the Niagara Falls and conducted by wires to the Canadian side must pay a duty of 20 per cent. as "an unenumerated article."

Electric Light Buoys.—The North German Lloyd steamer "Havel" was entering New York harbour in a fog on the 7th inst. when the pilot discovered that the ice had wrecked the electric lights on the buoys. He attempted to put back, but in doing so the vessel grounded. The vessel was floated on the following day.

Bordeaux Tramways.—The chairman of the Bordeaux Tramways Company told the shareholders on Wednesday that he thought the time was fast approaching when the shareholders must consider the question of adopting electricity for their tramways, and that he hoped to bring that matter forward at the next meeting.

Electrical Communication with Lighthouses.—A daily paper states that it is impossible at present to state when the Earl of Mount Edgcumbe's Commission on Electrical Communication with Lighthouses will finish their work, but it is scarcely probable that they will be able to do so before the close of the year.

Telephony and Military Operations.—It is stated that the military district of Kieff is shortly to be connected by telephone with the Odessa military district, Nicolaieff, and Sebastopol, and it is expected that all the chief military and naval points in South Russia will be joined by telephone before the end of the present year.

Students of the Institution.—A students' meeting of the Institution of Electrical Engineers will be held in the library of the Institution, 28, Victoria-street, on Friday next, the 22nd inst., at 8 p.m. The following paper will be read: "Lead-Covered Cables," by Mr. Mervyn O'Gorman (Fowler-Waring Cables Company).

Royal Meteorological Society.—An ordinary meeting of this society will be held at 25, Great George-street, Westminster, on Wednesday next, the 20th inst., at 7.30 p.m. A lecture, which will be illustrated by experiments, will be given by Mr. W. N. Shaw, F.R.S., on "The Motion of Clouds Considered with Reference to their Mode of Formation."

Cardiff Central Station.—We must sympathise with Mr. Massey and the contractors for the Cardiff central station. Complaints have frequently been made in regard to the arc lighting, and to a certain extent in the case of the incandescent lighting. It seems as if all the blame for the present position of affairs rests with the Lighting Committee of the Corporation.

Lecture.—A lecture on electric lighting was delivered on Friday by Mr. J. C. Howell before the Llanelly Chamber of Commerce. In the course of his address he said that where companies were properly managed electric lighting could be made to pay. He was extremely anxious that they should do the right thing from the start in Llanelly, and that could only be done by securing the services of an expert.

Ealing Central Station.—It was mentioned by Mr. Warner at the enquiry held last week at Bath, that at Ealing heat from the destructor was being used for the purposes of raising steam for electric light purposes. Mr. T. O. Callender, however, denied this. He said he was one of the contractors for that electric light installation, that he was there on Friday, and that the connecting flue had not been constructed.

The Albert Medal.—The council of the Society of Arts will consider the award of the Albert medal for 1895 early in May, and they, therefore, invite members of the society to forward to the secretary on or before the 13th of April the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit for promoting arts, manufactures, or commerce."

Telephony.—The National Telephone Company have issued an intimation in Edinburgh that arrangements have now been made with the Post Office whereby the company's subscribers will be able henceforth to communicate by means of the Post Office trunk wires between the following towns: Belfast, Birmingham, Bristol, Cardiff, Exeter, Glasgow, Leeds, Liverpool, Manchester, Newcastle, Newport, Plymouth, and Swansea.

Northern Society of Electrical Engineers.—The satisfactory position of this society is indicated by the report for the session 1893-94, and the statement of account

Digitized by Google

for the year ended 1894. The report, which shows that the roll of the society comprises 122 members and three associates, is followed by a list of the names of the president, council, and officers for the current session, together with the rules and regulations of the society.

Guernsey Electric Tramway.—A correspondent writes to a Leeds paper stating that on this line the fare is 1d. for three miles, with special rates for workmen and school children. The working expenses, he says, are 5·791d. per car mile, but it must be borne in mind that coal and all other materials are more expensive in Guernsey in consequence of the long carriage. The actual running expenses—such as coal, oil, etc.—are less than 4d. per car mile.

Cable Rates to South Africa.—It is stated that the negotiations for the reduction of the cable rates to South Africa have now been completed, the Imperial Government, through the Treasury, having agreed to pay its share of the subsidy. The difficulty with respect to the traffic over the Portuguese territory on the East Coast has been arranged, as have the other obstacles which have arisen from time to time. The reduced rates will come into force in April.

The Proposed Pacific Cable.—The latest idea for the construction of a Pacific cable is contained in a New York telegram dated the 9th inst. The despatch states that a project is now under consideration whereby Russia, France, Japan, and Hawaii will join with an American company in constructing a telegraph cable from San Francisco to Hawaii, and thence to Japan and the French islands in the Pacific. The negotiations, it is reported, are almost concluded.

Chesterfield Institution of Engineers.—A special meeting of the Chesterfield and Midland Counties Institution of Engineers (Mr. William Spencer, president, in the chair) will be held in University College, Nottingham, to-morrow (Saturday), the 16th inst., at 2.30 p.m. The business includes the presentation of a paper on "Continuous-Current Dynamos and Motors: Choice of Plant, Fixing, and Driving, Usual Faults and their Remedies," by Mr. Lancelot W. de Grave.

Books Received.—We have received a copy of "Meteorology," by Mr. Thomas Russell, published by Messrs. Macmillan and Co., of London and New York; a copy of "The Telegraphists' Guide to the New Examinations in Technical Telegraphy," by Mr. James Bell, A.I.E.E., issued from the offices of *Electricity*, 29, Ludgate-hill, E.C.; and a copy of "Street Railway Investments," by Mr. Edward E. Higgins," published by the Street Railway Publishing Company, New York.

Electric Construction Company's Works.—A reprint has been issued in pamphlet form of an article which appeared in the *Machinery Market* descriptive of the Bushbury works of the Electric Construction Company at Wolverhampton. Besides giving a historical sketch of the company and descriptions of the works and important undertakings carried out by them, the pamphlet contains illustrations of the works and information concerning the leading specialities made by the company.

Self-Contained Electric Locomotive.—The Electrical Power Storage Company have received from Messrs. Edwin Andrén and Co., of Göteborg, a letter testifying to excellent working of an electric locomotive supplied to the Skutskär sawmills in January, 1892. Since that time the accumulators with which the locomotive is equipped have been charged 631 times—in all about 2,000 hours—and up to the present not a single plate has either been destroyed or been required to be replaced. The plates continue to be in full working order.

Gas versus Electric Light.—The end of the dispute between the Limoges Municipality and the gas company, on the ground of the former having licensed an electric company to the detriment of the latter, is that in the meantime the electric lights have had to go out. The *Gas World* states that this is the fourth case—Saint-Etienne, Montluçon, Argentan, and Limoges—in which the French Courts have compelled municipalities to keep to the terms of their agreements with gas companies in this respect.

Leeds Tramways.—The Leeds Corporation Tramways Bill, against which petitions have been deposited by the Lancashire and Yorkshire and Midland Railway Companies and the Yorkshire House-to-House Electricity Company, came on Tuesday before the House of Commons Committee on Standing Orders. After a brief deliberation in private, the agents for the Bill were informed that compliance with standing orders would be excused on the same conditions as were imposed in the House of Lords—namely, that the powers relating to the construction of generating stations should be struck out of the Bill.

Magnetism and Compasses.—In the past it has been the practice, the *Times* states, to "swing" vessels of the Royal Navy for the purpose of ascertaining the effects of the dynamos on the compasses, but in future this is to be discontinued on second-class cruisers, which are fitted with automatic switches for obviating the effects of the dynamos in disturbing the compasses fitted on the aft bridge and other compasses fitted in the aft part of the ship. The accurate working of the switches is tried by observing the deviation with the ship's head on the north or the south point, first, with both dynamos running; secondly, with the starboard dynamo running; and, thirdly, with the port dynamo running.

Iron and Steel Institute.—A batch of pamphlets, being reprints from the *Journal* of the Iron and Steel Institute, has been forwarded to us by the secretary. The pamphlets include, amongst others, "Notes on Electric Power," by Mr. D. Selby-Bigge; "Early History of Crucible Steel," by Mr. R. A. Hadfield; "Colour Gauges for Carbon Testing," by Mr. W. G. McMillan; "Influence of Aluminium upon the Carbon in Ferro-Carbon Alloys," by Mr. T. W. Hogg; "The Manufacture of Coke," by the late R. de Soldenhoff; "The Manufacture of Steel in the Open Hearth," by Mr. J. A. Lencauchez; and "Iron and Steel Industries of Belgium," by Prof. A. Gillon. The discussion on the papers is also given.

Telephony in Germany.—The Imperial Diet on Monday discussed the estimates for the posts and telegraphs. The first demands submitted to Dr. von Stephan included a reduction in the charges for the use of telephones. The Secretary of State remarked in regard to this suggestion that Germany was far ahead of other countries in telephony. In the whole of France there were not so many telephones as there were in Berlin alone. In the empire at large there were 378 places with telephonic communication, with a total of 84,920 instruments. But the financial objections against the reduction of the charges for the telephones and against an increase in the weight of single letters did not permit him to take the desired reforms in hand.

Indiarubber-Covered Cables and Wires.—A revised price-list of pure and vulcanised rubber-covered cables has been issued by Messrs. Johnson and Phillips, who occupy a prominent position in this branch of industry. The list contains a table of the gauge, sectional area, and carrying capacity of copper conductors, and gives details

Digitized by Google

of the various classes of cables and wires made by the firm. Apart from the fact that the firm's cables are used by many of the most important electrical wiring contractors, Messrs. Johnson and Phillips are also supplying quantities of high-pressure rubber-covered cables to different supply stations for underground work. As an instance of the test to which these cables are put, it may be mentioned that they are tried with an alternating current of from 4,000 to 10,000 volts from core to earth.

Electric Tramway at Nice.—Some time ago, M. A. Sénéchal, manager of the Nice Zoological Gardens, obtained a concession for the construction and working of an electric tramway between Nice and Cimiéz. This line, which is about to be set in operation, has been laid down by Mr. G. Averly, of Lyons, the gauge being 60 centimetres. The tramway is to be worked by storage battery cars of the open side and end type, and having a passenger capacity of 32 persons. The generating station contains plant for the charging of the batteries. The cells are of the Laurent-Cely type, and each car is equipped with 90 cells, capable of furnishing sufficient energy for driving the motors and car for one hour, or, say, three journeys. The weight of each car battery is 2½ tons, and the car is equipped with two electric motors, driving the axles by means of toothed gearing. Experimental runs have already been made with some of the cars.

Prevention of Pipe Corrosion.—A communication dealing with rail-bonding and its bearing on electrolytic corrosion, by Mr. George P. Low, is given in the February issue of the *Transactions* of the American Institute of Electrical Engineers. It forms a sequel to the discussion of a paper by Mr. J. H. Farnham on the "Destructive Effects of Electric Currents on Subterranean Pipes," read before the institute in April of last year. Mr. Low concludes that the art of rail-bonding now appears to have been perfected, and the damage that has been caused by corrosive electrolysis may be attributed to defective bonding, for without doubt proper main-to-track, rail-to-rail, and track-to-dynamo bonding will cure the ill almost without exception. Should the street railway companies delay in correcting the evil it is probable that municipal authorities will take action for the protection of citizens in their vested interests, in which event the conditions now existing may be further and seriously complicated by ill-advised municipal exactions. The problem of eliminating electrolytic corrosion is, in brief, simply one of judicious bonding.

Metric System of Weights and Measures.—Mr. Alex. Siemens was the first witness called on Tuesday on the resumption of the hearing by the Select Committee of the House of Commons of evidence in connection with weights and measures. He declared himself in favour of the metric system, and stated that he had adopted it at his own works for the smaller measurements. Engineers generally were obliged to use the metric system for engines which were ordered from abroad. He thought that there would be a very considerable saving of work if the metric and decimal systems were adopted in this country. The system of testing weights and measures in Germany was practically the same as that obtaining in England. If the metric system were adopted by this country, he believed that the present staff of inspectors could easily standardise metric weights and measures. When the change to the metric system was made in Germany it was found possible to convert a large proportion of the weights and measures then in existence; and he did not think that it would be at all difficult to make English weights available under the metric standard. The retail traders of Germany made no great objection to the metric system; on the contrary, they rather welcomed it. They soon recognised its advantages over the old system, and its smaller liability to admit errors. The same might be said with respect to the decimal coinage.

Electro-Harmonic Society.—A smoking concert will be held on Friday, the 29th inst., at the St. James's Hall Restaurant (Banquet-room), Regent-street, W., commencing at eight o'clock. The following is the programme: Part I.—Quartette, "Robin Adair," the "Vernon Lee" Part Singers; song, Mr. Wingrove Ives; pianoforte solo, "Tarantella" (Moskowski), Mr. Alfred Izard; song, "The Sailor's Grave" (Sullivan), Mr. Harry Stubbs; humorous recitation, "Astronomy Made Easy" (Anon), Mr. W. G. Churcher; violoncello solos, "Herbstblume" and "Papillon" (Popper), Mr. Allen Gill; song, "Star of the Desert" (Bonheur), Mr. Harry Marriott; humorous sketch, "Ganthony's Grotesques," Mr. Robert Ganthony. Part II.—Quartette, "The Ash Grove," the "Vernon Lee" Part Singers; song, "The Wonders of the Deep" (W. H. Jude), Mr. Wingrove Ives; instrumental trio, "Molto Allegro" from Op. 49 (Mendelssohn), Messrs. T. Gatehouse, Allen Gill, and Alfred Izard; humorous recitation, "The Cricket Club of Red Rose Flat" (Wood), Mr. W. G. Churcher; violin solo, Mr. T. E. Gatehouse; song, "A Spring Song" (Leoni), Mr. Harry Stubbs; humorous sketch, "Black and White Art," Mr. Robert Ganthony.

Electrical and Allied Trades Section.—A meeting of this section of the London Chamber of Commerce will be held at Botolph House, Eastcheap, E.C., on Monday, the 18th inst., at 12 noon, to deal with the following business: (1) To consider the proposed telephone agreement between H.M. Post Office and the National Telephone Company, and what steps should be taken to obtain an expression of the views and adequate representation of the interests of the commercial community before the parliamentary enquiry to be held on the subject; (2) to consider the report of the Board of Trade Departmental Committee on Light Railways, and whether any action should be taken in connection with the Bill about to be introduced by the Government; (3) to consider what action, if any, should be taken in connection with the appointment of a select committee of the House of Commons to enquire "whether any and what changes in the present system of weights and measures should be adopted"; (4) to consider the Government Factory and Workshops Bill, and whether any action should be taken in connection therewith; (5) to consider whether the section should offer a prize or prizes for proficiency in electrical subjects, under the commercial education scheme of the Chamber; (6) to appoint representatives of the section on the following standing committees of the Chamber: Bills of Lading Committee, Commercial Education Committee, Commercial Law Committee, Exhibitions Committee, and Postal Committee.

Employes in the Post Office Service.—The secretary of the London Trades Council recently forwarded to the Postmaster-General a copy of a resolution passed at a delegate meeting of the council, calling on him "to observe the same conditions and customs in the electric lighting department at Mount-pleasant as are observed in the various shops in the London district, and abolish the present system of piecework in existence at the instrument factory at Holloway, where it is possible for a recognised skilled mechanic to earn the sums of 7s., 9s., and 11s. for three consecutive weeks' work." The following reply has now been received from Mr. S. Walpole: "I am directed by the Postmaster-General to acknowledge the receipt of your letter of the 21st ult., enclosing copy of a resolution adopted at the general delegate meeting of the London Trades Council on the 14th ult. Mr. Arnold Morley cannot admit that the charges made by the deputation which he received on June 29 last, consisting of repre-

Digitized by Google

sentatives of the Electrical Trades Union, Scientific Instrument Makers' Trade Society, and members of the executive, have been proved by the answer which he caused to be addressed to you on November 9. On the contrary, he believes that that answer disposed of the points brought forward by the deputation. As regards that part of the resolution which recommends the abolition of piecework, I am to inform you that since the date on which the resolution was carried, the men employed at piecework rates at the instrument factory have unanimously adopted a memorial asking that no change may be made in this respect."

The Government and Telephony.—In the House of Commons on Wednesday Mr. T. Ellis moved that the Select Committee on Telephony should consist of 15 members; that Captain Bagot, Mr. Baird, Mr. Benn, Sir C. Cameron, Mr. John Ellis, Sir J. Fergusson, Sir J. Goldsmid, Sir J. Gorst, Mr. Grant Lawson, the Solicitor-General, Mr. Arnold Morley, Mr. Moulton, Mr. Snape, Lord Stanley, and Mr. Tulley be members of the committee; and that the committee should have power to send for persons, papers, and records; five being a quorum. Mr. A. C. Morton appealed to the Postmaster-General to reconsider the list of names with the view of giving a larger representation to the City. Mr. A. Morley said that London already had three members, which was more than its share as compared with the representation of the rest of the country. Mr. A. C. Morton said that two of the three members represented the County Council, and it could not be said that one was a fair representation of the City. He persisted in his objection, and the matter therefore stood over.—The Highways Committee of the Leeds City Council had under consideration on Wednesday a communication from the parliamentary agent of the London County Council, suggesting that a few of the leading corporations should appear before the Select Committee of the House of Commons appointed to consider the subject of telephones in relation to municipalities, and the sufficiency of telephonic arrangements. The committee resolved to agree to the suggestion, and a committee, composed of the Mayor, Alderman Ward, and Alderman Firth, was appointed in regard to the matter.

Water Power in Scotland.—In connection with the scheme referred to in our issues of the 22nd ult. and 1st inst. for the utilisation of the Falls of Foyers, near Loch Ness, Mr. A. C. Morton asked the Secretary for Scotland, in the House of Commons last week, whether his attention had been drawn to the subject, and, if so, whether he would take measures to prevent the destruction of what was of national interest, especially to tourists. Dr. MacGregor wished to ask the right hon. gentleman, as these falls were part of his constituency, whether there were not two sides to the question? Whilst he should deprecate the destruction of such grand and beautiful falls just as much as anybody else would, he could not help asking the right hon. gentleman to consider whether, especially as public works and factories were so scarce in that part of Scotland, it was not more desirable to encourage work of this kind than to discourage it, so that some employment might be found for the people in the locality. In reply, Sir G. Trevelyan said that his hon. friend had given him a serious problem to solve, but it was one which lay rather with the County Council than with him. He was informed, however, that the County Council had not yet met to consider the question referred to, but a meeting of the County Road Board, preparatory to holding a meeting of the Council, was called for Friday next to consider whether the Aluminium Company could be allowed to submerge roads near Foyers in carrying out their proposed works. The company denied that the falls would be destroyed, but the volume of water would no doubt be lessened at certain seasons of the year. The question, however, was receiving the attention of the County Council, who were, it appeared to him, the proper authorities to deal with the matter.

Potential Differences between Metals and Electrolytes.—In the *Journal* of the Chemical Society there appears an abstract of a paper by Mr. V. Rothmund in the *Zeit. Physikal. Chem.* on this subject, in which it is stated that a capillary tube containing mercury or a liquid amalgam dips into a small cup containing mercury, covered by the electrolyte, and the capillary and electrolyte can be brought to any required difference of potential by means of a set of resistance coils and a Leclanché cell. The capillary tube is connected with a manometer, and the mercury always brought to the same point by an increase or decrease of the manometric pressure. When the E.M.F. due to the cell is equal to that between the amalgam and electrolyte no charge is received, and the surface tension is a maximum; the method hence consists in varying the difference of potential due to the cell until the manometric pressure required to bring the amalgam to its constant point reaches a maximum. Measurements were made with mercury and amalgams of lead, bismuth, tin, copper, zinc and thallium, the electrolytes being sulphuric acid saturated with a salt of the dissolved metal and with a complex mercury salt such as mercuric potassic iodide. The E.M.F. of various galvanic chains were calculated from the results and compared with those obtained by direct measurement. The agreement was in most cases very satisfactory, so that the potential difference between the two metals or two electrolytes has but a slight influence on the E.M.F. of the cell. Variations occurring in the cases of the amalgams of tin, cadmium, and thallium are probably due to the action of the acid on the surface of the amalgam. Discordant results were also obtained in the experiments with the complex salts, where it is noticeable that the absolute value of the surface tension at the maximum was below the normal value, in which case the author does not consider the method to be applicable.

The Government and Telegraphy.—The Postmaster-General, speaking on Wednesday at a meeting of the Association of Chambers of Commerce, said that the time might come when the Department with which he was connected might have more direct control over telegraphic communication, but at present, with the exception of certain cables across the Channel to the Continent of Europe, they had no control over the foreign Imperial telegraphic cables of the world. They were in the hands of companies. He should certainly put no difficulty in the way, but should be prepared to give the advantage of the experience he had gained at the Post Office in helping on any reasonable extension of the system of Imperial communication between the different parts of this great Empire. In regard to the substitution of underground cables for overhead wires, he had had an estimate prepared for a system which would allow underground communication between London and 66 of the principal provincial towns and 88 junction lines between the principal provincial towns, and he found that the cost would be something like 2½ millions sterling. That was an amount which, in view of the serious and heavy loss on the Telegraph Department of the Post Office, he should certainly view, and he was certain the Treasury would view, with grave misgiving. They had met the difficulty of interruption from storms and other obstructions by creating alternative systems of communication between telegraphic centres.

Digitized by Google

To the West of England there were two routes, and to the North three, and he was confident as time went on these difficulties would be minimised. The Post Office had developed the telegraphic system of this country during the past 25 years in a way unequalled in any other country of the world. The Government had now taken over the trunk telephone wires of the country, and he believed that in the development of the telephonic system equal activity would be shown.

Ventilation of Street Boxes.—The London County Council is insisting upon proper means of ventilating the street boxes being adopted by existing companies in cases of any extensions of their mains. The House-to-House Company desire to lay mains in Cheniston-gardens, Cromwell-road, and in Brechin-place. Sanction has been given to this proposal on condition that the mains are laid under the footways wherever it is found practicable to do so; that the low-pressure mains be placed 9in. below the underside of the paving, and those of high-pressure at least a foot lower; that no pipes of a larger diameter than 3in. be used; that no street boxes be constructed until full details showing adequate provision for ventilating them shall have been submitted to and approved by the Council's chief engineer; and that separate boxes be used for the high and low pressure mains respectively. The London Electric Supply Corporation, who want to lay distributing mains in Pavilion-road, Daycott-place and street, Cadogan-gardens, Dilke-street, Cheyne-walk, and the Chelsea-embankment, can do so by putting the mains under the footways 9in. below the underside of the paving wherever practicable, but they must not construct street boxes until the positions for and the mode of construction showing adequate provision for ventilating the boxes, have been approved by the Council's chief engineer. Moreover, the Council say that all cables crossing the boxes must be supported from below in the boxes; all service lines or small cables must be protected where leaving the boxes by an extra lead covering or by wooden stoppers, and also have a copper wire of sufficient size carried from the service to the main cable in good connection with the lead or iron outer casing; and the ends of all mains terminating elsewhere than in a box are to be securely protected by iron caps, in addition to any other covering. The Westminster Company, who intend to lay mains and construct street boxes in Gardiner's-lane, Caxton-street, and James-street, are ordered by the County Council to submit to its engineer details of the street boxes to be used, showing adequate provision for ventilating them, and the covers of the boxes are to consist of iron frames filled in with materials to suit the paving.

Electrical Energy from Cold Combustion of Gas.—A note on this subject appears in the New York *Electrical World* from the pen of Mr. Carl Hering. The writer says: "In connection with the recent experiments of Dr. Borchers, which have been attracting so much attention, the following simple little experiment made in 1883 by Mr. von Dobrowolsky and myself, at the suggestion of the former, may be of interest, as it seems to show conclusively that a cell can readily be made in which the cold combustion of coal gas (or at least some constituent part of it) with atmospheric air will take place, yielding its energy in the form of an electric current. Two carbons, such as used in Leclanché cells, were carefully cleaned and platinised with platinum black; they were then placed in dilute sulphuric acid and kept short-circuited for some time in order to discharge them, should there be anything different in the two causing a difference of potential. One was then placed in a jar containing ordinary illuminating gas from the street mains and the other was held in the air. After a while they were inserted in the dilute sulphuric acid and connected to a crude galvanometer made of a small coil of wire around a pocket compass. The current obtained when started and stopped at proper time intervals caused the needle to spin around on its pivot with considerable speed. It may, therefore, be said that a motor, although only an infinitely small one, was run with the energy thus obtained. No further measurements were made, as it was considered to be of no practical interest and as we had no suitable measuring instruments at the time. I believe that the problem of the conversion of the energy of coal into electrical energy without the aid of that frightfully wasteful converter, the steam engine and boiler, will be solved first by some of the numerous possible indirect ways. If scientists and inventors would direct their attention to these rather than to the direct methods, we would, I think, be relieved much sooner from the necessity of using the wasteful steam engine and boiler, which, although very useful in the absence of something better, must still be regarded as merely a temporary, unsatisfactory makeshift. The efficiency of the engine-boiler converter is so very low that it will require but a very poor and inefficient electrical converter to relegate it to the museums."

Lighting of Joiners' Shops.—An interesting installation has just been completed for the lighting of the new joiners' shops recently built by Messrs. J. L. Thompson and Sons, North Sands, Sunderland,. The plant consists of a "Tyne" compound-wound dynamo, capable of giving 400 amperes at 65 volts when running at approximately 600 revolutions per minute. The machine is fitted with an extended bedplate with outer bearing and a very heavy flywheel, so that an absolutely steady light will be obtained when driven by a gas-engine, but at present the dynamo is operated by the existing steam-engine which drives the bending rolls and other machinery in the ship-repairing yard. The current from the dynamo is taken to a main switchboard, and is from there divided into three circuits. One circuit is taken overhead to the joiners' shop, the second is carried along the jetty for energising cluster lights for repairing oil ships, etc., and also for working electric deck planers and drilling machines, and the third circuit is provided as spare, as the firm contemplate applying electricity for other purposes. A distributing switchboard is placed in the joiners' shop on the first floor, and from this board 18 arc lamps of 2,000 c.p. each are fed, the lamps being on separate circuits so that any lamp can be switched on or off as required. The arc lamps are exceedingly simple, and are fitted with light flashed opal globes with solid bottoms, so that it is impossible for any sparks or pieces of carbon to fall down. This is an extremely important matter in a joiners' shop where shavings are lying about, and these lamps particularly meet the requirements of the case. Five arc lamps are placed on the ground floor and 13 on the first floor, the ground floor being reserved for heavy plant and the first floor for light machinery. The varnishing-shop and light joiners' shop are lighted with 16-c.p. incandescent lamps, there being between 40 and 50 lamps of this type. Along each side of the first floor and ground floor a separate circuit is laid with wall plugs about every 10ft., portable hand lamps being provided so that the shafting or underside of any of the wood-working machines can be quickly examined. This installation is of a very complete description, and owing to the abundance of light provided there is no doubt that Messrs. Thompson will find a very great advantage in the rapid production of their work by adopting the electric light. Messrs. Ernest Scott and Mountain, Limited, of Newcastle-upon-Tyne, have carried out this installation.

NEW ALTERNATING-CURRENT ARC LAMP.*

Amongst the numerous applications of polyphase currents, their use in regulating arc lamps, by the Nuremberg Electricity Company, formerly Schuckert and Co., is interesting and important. All arc lamps for alternating currents which have hitherto been used or proposed have almost invariably had a rack arrangement and gearing, which are released as soon as the consumption of carbon has so far advanced that the pressure at the electromagnets has reached a certain limit. This intermittent regulation is the cause of certain inconveniences, as, for example, irregularity in the light at different times. The regulation of this new arc lamp is, however, continuous, the carbons being steadily pushed forward.

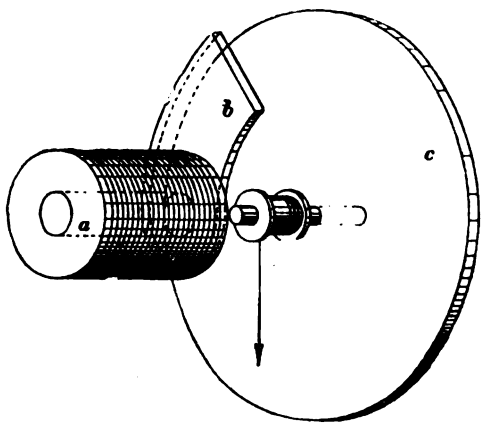

FIG. 1.

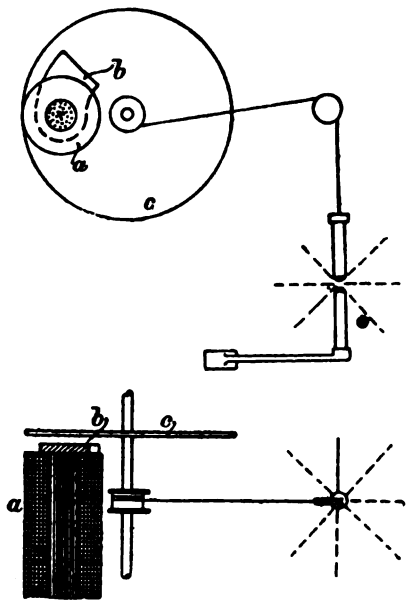
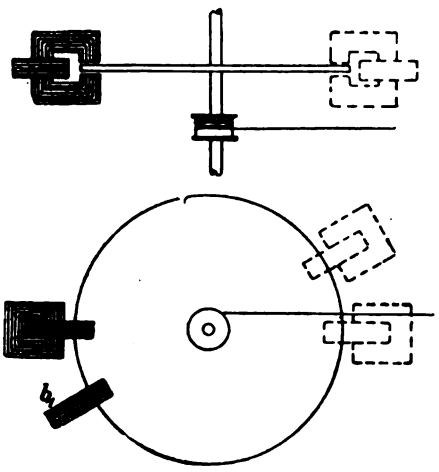
The arrangement is shown in Figs. 1, 2, and 3. A copper disc, *c*, revolves in front of an electromagnet, *a*, whose core is made of laminated iron, and whose poles terminate in strips like *b*, or some other suitable shape. When an alternating current is passed through the coil the copper disc is caused to revolve, because by each change of poles first the core of the electromagnet and then the



FIGS. 2 AND 3.

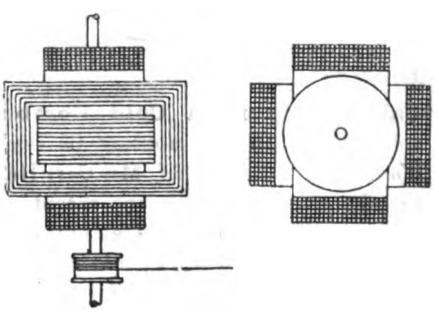
strips, *b*, are magnetised; the parts furthest away from the electromagnet last—*i.e.*, there is a magnetic wave from the core of the electromagnet to the extremities of the strips. By the causing of eddy currents in the copper disc a tendency to rotate is developed, varying according to the force of the current and number of times the poles are reversed, and having a tendency to take the disc round with it. If the disc is connected with the carbon-holder by a suitable mechanism, in such a manner that a constant weight balances the tractive force (in the drawing this is done by means of a cord), we then have an arrangement equally suitable with a single coil for lamps on a main or a shunt circuit, or with two coils as a differential lamp. Modifications of this arrangement have been introduced. In Figs. 4 and 5 a coil is shown on the left, whilst the influence on an adjoining core, b_1, causes the displacement of the field. On the right is another variation of the arrangement; two electromagnets are shown in dotted lines. Instead of this, four can also be used, spaced symmetrically 90deg. apart, or two close together, as shown in Fig. 5. A periodical displacement of the field can also be caused by having both electromagnets in the main current, or both in the shunt-current circuit, but by different winding, or with



FIGS. 4 AND 5.

differently-shaped iron cores, they have different coefficients of self-induction, and therefore a difference of phase arises. Figs. 6 and 7 show an arrangement by which the magnetic field turns in a well-known manner (Ferraris), and a rotary impulse is exercised on the metallic body. The copper disc is replaced by a cylinder, which can be made of copper or another conducting material. In the drawing, however, the body which rotates is made of thin discs of iron insulated with paper, so that the effect of the eddy currents is compensated by the retarded magnetism.

Fig. 8 and 9 show an elevation and a plan of the type of arc lamp carried out. On the plate, *h*, are four small columns, *i*, which carry the whole mechanism. By means of two cross-pieces, *d*, they carry the electromagnets, *a*, with their iron cores, *b*, as well as the iron pieces, b_1 b_1, and, lastly, the metallic disc, *c*. The cores, *b*, of the magnets, *a*, are most suitably made of thin sheet iron; whilst the



FIGS. 6 AND 7.

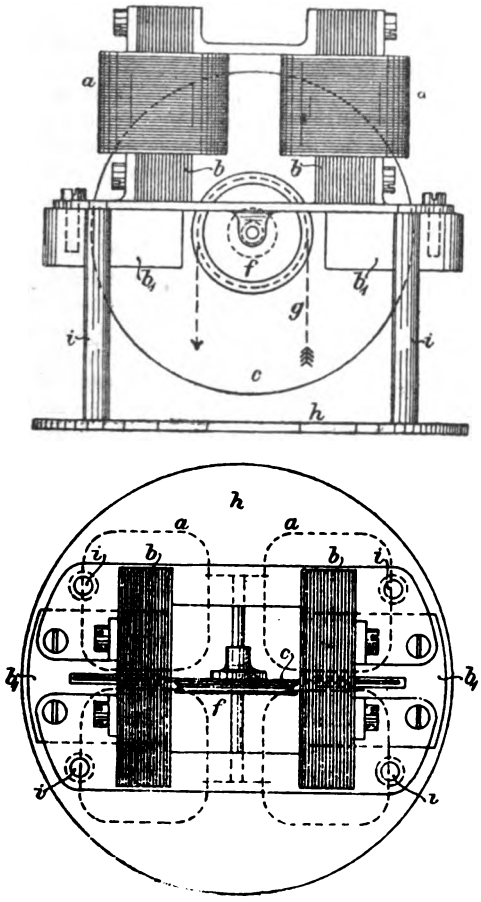
pieces, b_1 b_1, had better be of solid material. The metallic disc, *c*, revolves between the cores, *b b*, and through openings in the iron pieces, b_1 b_1. A pulley, *f*, is in communication with this and carries the cord, *g*, which leads to the carbon holders.

The manner in which the mechanism of the lamp works is as follows: Through the weight of the carbon-holder and carbons the latter have sunk until the points touch. The alternating current which supplies the lamp flows through the electromagnets, *a*, and periodically, as the poles change, magnetises the iron cores, *b b*. The pieces,

* Abstracted from the *Elektrotechnische Zeitschrift*.

Digitized by Google

b_1 b_1, next become magnetised, but not till after the cores, or, in other words, a magnetic wave passes from the laminated core to the solid pieces of iron. The wave takes its rise in the core, passes into the pieces of iron, and there dies away. This magnetic wave causes eddy currents in the copper disc, which create an attractive force, and therefore a tendency to rotate in the opposite direction to the wave. The copper disc is thus caused to revolve, and by means of the pulley and cord this brings the carbons apart. Hence a weakening of the power of the electromagnets takes place until the strain on the copper disc is balanced by the weight of the carbon-holder.



FIGS. 8 AND 9.

To obtain a practical and useful construction, it is necessary that there should be a considerable difference in phase in the periodically changing magnetism of the two pieces of iron, as it is only thus that a compact form becomes possible. With this object the pieces of iron which are to be secondarily excited are separated by a layer of low permeability, so that the laminated electromagnets induce electricity in the disc, and the Foucault currents in the disc work on the secondary masses of iron.

THE SCIENTIFIC FOUNDATIONS OF ELECTRICAL ENGINEERING.*

BY F. G. BAILY, M.A., MEMBER.

There is probably no branch of engineering which is more intimately connected with purely scientific knowledge, and which has received more attention from scientific men, than electrical engineering. The novel character of the forces which it employs, their intangibility and mysterious nature, appeal strongly to the imaginations of the uninitiated, and seem to set apart everything connected with electricity as a class of phenomena about which very little is known or understood. On the other hand, a certain amount of familiarity with the more usual phenomena and the acquisition of several formulæ has produced in some minds a profound conviction of the truth of electrical theories, with an implicit faith in the accuracy of electrical measurements and the potency of calculation. While leaving the former attitude of mind to the gradual effect of familiarity, I wish to mention in this paper some of the limits to which we are still subject and some of the errors to which we are specially liable.

The most powerful aid to improvement, and the greatest source of confidence in engineering practice, is undoubtedly by accuracy of measurement of effects and quantities in units which are common to all branches of physical knowledge. It is, therefore, useful sometimes to examine our foundations and realise what they mean. In accordance with its close connection with pure science, the units employed in electrical engineering have been based on the so-called "absolute" system of units—that in which the centimetre, gramme, and second form the fundamental quantities, the definitions of which depend on the physical properties of certain portions of the universe. Physical science refers all its measurements to these three fundamental units, and recognises no others. As these units are independent, all calculations based on them may be accepted as rigidly accurate, and strictly comparable with one another. Abstract calculations are not, however, of much direct use to the engineer, and something more definite is required. Now, the E.M.F. of a battery, the current in a lamp, or the resistance of a piece of wire does not appear to be very closely related to grammes, centimetres, and seconds, and, in fact, they can only be numerically estimated by indirect experiment. After a long series of extremely careful work, the values of electrical and magnetic quantities have been determined to a certain degree of approximation, so that the values of any particular resistance can be expressed in centimetres and seconds to an accuracy of ·01 per cent., or even less.

The electrical and magnetic units are derived from the centimetre-gramme-second through the mechanical forces which the various quantities exert, starting from the force between two magnetic poles, and the force on a magnetic pole in a magnetic field. Hence current is measured by the strength of the field it produces, and E.M.F. by the motion of a conductor in a magnetic field. Resistance is defined as the ratio of these two. This system, however convenient for scientific purposes, does not lend itself readily to the reproduction of the units. In practical work it is important that the standard values should be readily reproduced and easily compared to others. On this account the Board of Trade have laid down that the practical standards, while being made as closely equal to the true absolute values as possible, shall be independent of them and independent of possible future more accurate determinations of the true values. The ohm is defined as the resistance of a certain quantity of mercury of certain length, and the ampere as a current which will deposit silver out of a certain solution at a certain rate. The volt is, then, the E.M.F. necessary to drive one ampere through one ohm.

In accepting these definitions we really leave the centimetre-gramme-second system and found another one very closely related, but arranged on a different and more convenient principle. To what extent is this accurate, and to what accuracy can we compare electrical quantities on this system?

It must be confessed that the measurement of electrical quantities has not the same accuracy as the measurement of the fundamental mechanical quantities, and the laws upon which they depend are not to be depended on to the same extent. The laws of motion laid down by Newton have an accuracy which may almost be regarded as absolute. We have no reason for doubting them. The standards of length and mass may conceivably alter in the course of ages, but there is no evidence of such a change having taken place. But the electrical units are not so firmly established. The electrical resistance of standard ohm coils has been found to vary to a small extent, but this unit is the most satisfactory one, and comparisons between it and others can be made with considerable accuracy, one part in 10,000 being easily obtainable. The standard current depends on Faraday's law of electrolytic action, and though this may be theoretically very approximately

* Paper read before the Northern Society of Electrical Engineers, March 11, 1895.

Digitized by Google

true, its actual truth is marred by secondary actions, which prevent an accuracy greater than one part in 1,000. The volt depends on this, and therefore no measurement of current or of E.M.F. can be relied on beyond one part in 1,000.

This question of the limit of accuracy of measurement of the actual and relative values of quantities is one which is frequently ignored. There is no such thing as the knowledge of the absolute value of any quantity. We can only know its value to a certain approximation, and this should be definitely expressed by the figures used, and it is useless to try to push this limit beyond the limit of the standards. Sometimes this standard is very imperfectly known—*e.g.*, the value of the unit of heat is not reliable beyond one part in 400 at the most.

Frequently, however, the number of figures intended to denote a value are not justified by the degree of accuracy of the experiments by which it has been determined. The accuracy of a result is the accuracy of the weakest part, like the strength of a chain. The determination of other values involved to a much greater degree of accuracy is mere waste of time, while the quoting of them is deceptive. How often does one see a reading on a galvanometer consisting of two figures expanded by a long division, or by the use of seven-figure logarithm tables, into a result of some five figures. The last three figures are purely gratuitous, and are quite unreliable.

The same fictitious accuracy is often seen in the design of measuring instruments. It is not infrequently the custom to design voltmeters with an expanded scale over a short range, and to advertise accuracy of scale reading to $\frac{1}{10}$ volt at 100 volts—that is, an accuracy of one part in 1,000. This is merely the seven-figure logarithm over again, it being useless to magnify the scale beyond the size where the errors due to friction and the effects of temperature and residual magnetism become appreciable distances on the scale.

Under this head I feel compelled to mention an instrument for which I have a great admiration, and which has recently been eulogised before another society. I refer to the potentiometer. The delicacy is very great, almost comparable with that of the Carey-Foster method of comparing resistances, the Whitworth measurement of length, and the measurement of mass by the chemical balance, and for comparative values taken at short intervals of time it is unrivalled in its own line. But for actual values it is like using a delicate balance with a set of letter weights, or a Whitworth machine with a common foot rule, as standard. A delicate method of comparison is useless beyond the point of reliability of the standard, which in this case is one part in 1,000. Even this is by no means easy to attain. Such an accuracy on the silver voltameter requires great practice and very careful work, while the Clark cell requires just as careful handling. It is not an immutable thing—like a gramme weight of platinum, crystal, or gilt brass—but it is generally used with as little regard for its peculiarities. Notwithstanding its large temperature variation, the worker ignores its previous condition, and with a light heart applies a thermometer and a table of corrections, as if the E.M.F. had some direct connection with the mercury in the thermometer, instead of being related only by the very indirect and slow-acting conditions of solution or deposition of sulphate of zinc.

The essence of applied science is emphatically the power of measurement for the purpose of checking the accuracy of previously calculated or estimated designs, and for investigating the properties of materials used, in order to obtain data for future work. We may divide experimental research into three classes: (1) qualitative observation of the occurrence or non-occurrence of some phenomenon; (2) comparative quantitative observation of the variations of a phenomenon, with change of conditions; (3) absolute quantitative determination of the value of a phenomenon. The first two classes include the bulk of scientific research, for the absolute value is frequently of minor importance and depends on the particular piece of matter used, while the changes in value are common to a large class of bodies, and indicate physical laws. The determination of the absolute value of an important physical quantity to a high degree of accuracy is a matter of great difficulty, and forms the object of some of the most laborious investigations. To a large extent, however, the engineer can only deal in absolute values, because he immediately wishes to compare the result with that given by some other arrangement of his machinery. With him the all-important question is by what method a certain result can be most economically obtained, using the word "economy" in its widest meaning. For instance, a physicist or chemist may be interested in the various processes in the production of mechanical energy by the consumption of coal. The effect of varying the supply of air to the fuel, the wetness of the steam, the result of altering the initial pressure, the expansion and condenser pressure, the surface condensation under different conditions, and many other points, are all problems of scientific interest, and may be dealt with separately. But the engineer must take all of these points into consideration at once, make the best compromise that he can between conflicting requirements, and sternly require of each improvement that the resulting increase in efficiency shall not be swallowed up by the increase in cost of plant and labour. Finally, he must compare the total result with that given by some other means of obtaining mechanical energy, in order to make a final decision.

For this reason, therefore, the method of investigating engineering problems must, to a certain extent, differ from the purely scientific treatment. The scientist narrows the conditions of his problem and simplifies the phenomena until the result, though highly artificial, illustrates the action of a single law. For the engineer, on the other hand, it often seems difficult to avoid the combination of all the variables, and in consequence he hardly differentiates their individual effects, and does not always discern which of them are essential and where the point of weakness lies. That truly English panacea, a substantial factor of safety, is made to take the place of more precise knowledge, the additions being occasionally put in quite unnecessary places.

On the other hand, much time and energy is expended, especially by mathematicians, in elaborating hypothetical problems, the conditions being chosen to suit their method of analysis, and the desirability, and even the possibility of realising those conditions, being disregarded. This has been especially the case with alternating-current problems. It seems a field so evidently made for mathematical treatment of an interesting nature, and so impossible to attack by any less rigid method of reasoning, that one almost feels called upon to give up the use of such an unreasonable material as soft iron, and even to abjure the use of most dielectrics, in order to rest in the security of an analytical demonstration.

It is necessary, therefore, to beware of the spurious accuracy of the page full of mathematics just as much as the seven-figure logarithms. It has been pointed out, but the caution is frequently ignored, that mathematics is like a flour mill. The quality of the flour turned out is not better than that of the corn put in, and if not ground with due care and precaution, may be a good deal worse. If the data are unreliable, or if the proportion dealt with cannot be expressed as a mathematical function, the results can have but a very limited application. Examples of this are often met with in calculations of cost and efficiency, where wonderful coefficients and constants stand for interest, depreciation, labour, superintendence, load-factors, commercial efficiencies, plant efficiencies, and other quantities and values, which are familiar enough to the engineer, but of which the laws are only imperfectly known.

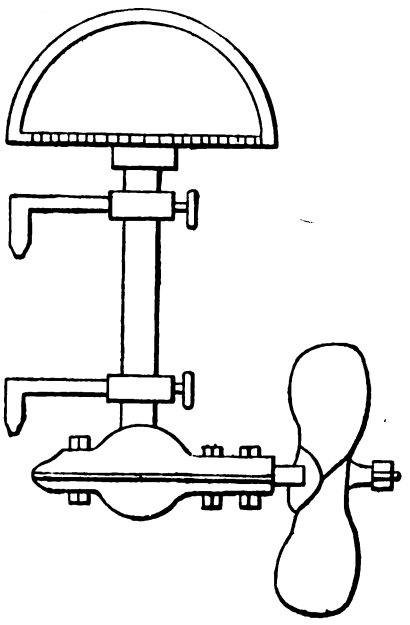
It must not be thought, however, that I wish to disparage scientific principles and methods in electrical or in any other branch of engineering. There is no other safe foundation, especially in electrical work. The agents and phenomena are so intangible and unusual that the old-time faculty of experienced intuition, by the light of which an engineer was supposed largely to work, is exceedingly difficult to cultivate, and frequently leads the possessor startlingly astray. What we want is more appreciation of actual working conditions in our mathematics, and a more scientific direction and greater breadth of applicability in our engineering experiments. This latter need is the weakest part of all engineering science, and the most important. An isolated case of a machine which works

Digitized by Google

well contributes little to knowledge. A similar case of one which works badly gives not much more information. But it is perhaps unreasonable to expect manufacturers to build a series of experimental machines, each differing slightly in one particular, to settle the absolutely best conditions, or if this is done, as has been sometimes the case, the world at large can hardly expect to have the benefit of the work presented to it. Moreover, workshops are not the best places for research, nor is engineering experimental work a pastime at which untrained players can get results of any value. It is so easy to obtain some sort of result in experimental work; it is so difficult to attribute it to its true cause and to eliminate all side issues. From the nature of the case, secondary actions crowd round the main point, and but few men have both time and ability for elucidating them. Much good work has been done in the factory, but, as stated above, it is generally of an unobtrusive nature. Much has also been done in physical and technical laboratories, and I venture to think that manufacturers, central-station and consulting engineers will find that a greater amount of sympathy with these institutions, and mutual assistance and collaboration with them, will result in true economy to themselves, and will greatly help to establish a firm scientific foundation for electrical engineering.

MCLACHLAN'S ELECTRIC RUDDER.

Some time ago we referred to this appliance, the object of which is to provide a propelling apparatus which may be attached to, or detached from, an ordinary skiff boat or canoe in a few minutes without the necessity of altering the vessel to which it is attached. The electric rudder,



which is illustrated herewith, weighs complete about 45lb., and the accumulators about 85lb. Sufficient energy is stored, we are informed, to propel the boat for eight hours at a speed of five to six miles an hour. The complete apparatus can be supplied at about one-third the price of an ordinary electric launch. Mr. E. A. McLachlan, of 55, Brighton-road, Stoke Newington, N., will be glad to furnish any further particulars.

INSTITUTION OF ELECTRICAL ENGINEERS, Mar. 14.

THE ELECTROLYSIS OF GOLD.

BY N. S. KEITH, MEMBER.

Obtaining the contents of gold from auriferous rocks and ores by means of solvents and subsequent precipitation is now attracting much attention, in both scientific and financial circles. Because in some of the practised plans electricity takes an important part in the operations, I think some electrical information relating to the matter will be acceptable; therefore this paper,

In fully considering the subject, we would have to enter into the question of the possible formation of native gold in rocks and ores by electro-deposition from the solvent waters of the earth by action of earth currents. But, as my paper is to deal more with practice than hypothesis, I shall leave that matter to the side, after stating a fact from which various deductions may be drawn. At the Dorn Gold Mine, in South Carolina, U.S.A., the rock formation is talcose slate. The soil is mainly the slate, disintegrated and decomposed. The slate is permeated by quartz veins, of all sizes, carrying gold. The soil is also auriferous. Particles of gold in the soil are all rounded, as if they had been submitted to attrition or solvent action; while those in the rock are crystalline in form, bright, and with sharp, well-defined edges. The gold from both positions is of equal quality, and the soil is of local origin. These facts seem to point to the present decrease of gold from the soil by solution, and increase, by deposition, of the gold in the rock.

Gold exists in natural auriferous materials in its native, or metallic, state, in irregularly-shaped pieces, from scarcely above the size of an atom to that of, say, a hundredweight. The larger pieces give no special trouble in securing after they are found, and do not call for our consideration in this paper. The smaller particles—those of which it takes thousands, perhaps, to weigh a milligramme—are the minute things which engage our present attention, and the efforts of metallurgists and electro-chemists the world over. The larger particles of gold are comparatively easily separated by amalgamation from the powdered auriferous rock, owing to their weight causing them to sink into contact with mercury surfaces; but the lighter particles float in the water used, do not come into contact with mercury, and are lost to amalgamation. Many efforts have been made to use electricity in obtaining this finely-divided gold. Most of them have been the dreams of unlearned enthusiasts, or the devices of dishonest men to obtain gold from the pockets of their dupes. The "Rae process," which has received so much consideration at the hands of "experts" in recent patent litigation involving the "cyanide process" of McArthur-Forrest, was an effort to simultaneously dissolve gold from ores and deposit it on a cathode by electrolytic action. It failed for at least two reasons: (1) the imperfect knowledge of electro-chemistry of its inventor; and (2) from the impractibility of causing the particles of gold to remain long enough in contact with the anode to be acted on electrolytically. The dynamos used by Rae at the Douglas Mill, in Nevada, about eight years ago, in the effort to gain practical results, were series wound, and without polarity protectors. Carbon anodes (sometimes, by reversal, the cathodes) were used, suspended in amalgamating pans, in which the pulp was agitated. The sides and bottoms of the iron pans were to be the cathodes. At least half the time they were the anodes. The mercury in the pulp was to combine with the precipitated gold and silver. By other inventors agitated mercury was made the cathode, and the fine gold was expected to mechanically "follow the current" into the mercury. Whatever of value the electric current conferred was due to the fact that there was a reduction at the cathode of oxides and salts of metals, thus keeping the mercury with a clean, bright, unoxidised surface, so that it was in a more receptive condition.

The amounts of various metals dissolved or deposited by a coulomb of current have been accurately determined. For example, one coulomb sets free 0·000162 grain of hydrogen. We may express this quantity as one hydrogen-coulomb = 0·000162 grain. From this we gain the following values:

One (dyad) copper-coulomb ... $= \frac{0{\cdot}000162 \times 63{\cdot}5}{2} =$ 0·0051035 grain of copper.

One (monad) silver-coulomb ... $= 0{\cdot}000162 \times 108 =$ 0·017343 grain of silver.

One (triad) gold-coulomb ..... $= \frac{0{\cdot}000162 \times 196{\cdot}6}{3} =$ 0·010611 grain of gold.

One (dyad) mercury-coulomb $= \frac{0{\cdot}000162 \times 200}{2} =$ 0·016200 grain of mercury.

One (dyad) iron-coulomb..... $= \frac{0{\cdot}000162 \times 56}{2} =$ 0·004536 grain of iron.

One (dyad) lead-coulomb..... $= \frac{0{\cdot}000162 \times 207}{2} =$ 0·016767 grain of lead.

One (dyad) zinc-coulomb..... $= \frac{0{\cdot}000162 \times 65}{2} =$ 0·005265 grain of zinc.

For a practical everyday-work unit, we may multiply each of the above quantities by 3,600 seconds in an hour to express the several quantities which an ampere will cause the solution and deposition of each hour. These quantities are as follows:

Hydrogen ampere-hour	0·5832	grain.
Copper ,, ...	18·37	grains.
Silver ,, ...	72·28	,,
Gold ,, ...	38·10	,,
Mercury ,, ...	58·32	,,
Iron ,, ...	16·30	,,
Lead ,, ...	60·36	,,
Zinc ,, ...	18·95	,,

Digitized by Google

It has been found by experimenters in the line, and it may be accepted as a law, that the various elements bear a relation to each other, which relation we name "electro-positive" or "electro-negative," according to the method of expression. Some call it their "electro-chemical" relation. The electro-positive metals tend to composition with electro-negative elements. Thus, potassium is always electro-positive to the electro-negative oxygen. Elaborate lists of the electro-positive and the electro-negative elements are in the text-books. They have the order of arrangement which puts the most electro-positive first, followed, seriatim, by the less electro-positive, till at the lower end the most electro-negative element appears. But one element may be electro-positive to another element in one solution, while in another solution the electro chemical relation is exactly the reverse. For instance, in dilute sulphuric acid iron is electro-positive to gold; but in a solution of cyanide of potassium gold is electro-positive to iron. The electro-positive is always more soluble in the solution than is the electro-negative. If the electro-positive and the electro-negative metals be connected electrically while in the solution, the solving action of the liquid on the electro-positive metal is much increased—somewhat in proportion to the difference in their electro-chemical relation. Such a combination makes a galvanic battery more or less approaching perfection. The placing of an extraneous source of electricity in such a circuit may increase the action, or even reverse it, depending on the direction of the electric current. The dynamic value of these actions may always be measured as watts by suitable instruments, such as an ammeter and a voltmeter.

The facts that gold could be dissolved by chlorine, aqua regia, bromine, cyanide of potassium, etc., have been known for many years. These facts have been put extensively into practical use for the obtaining of gold from ores by means of chlorine gas, in the Plattner process, and its modifications. From the solutions so obtained the gold is deposited by ferrous sulphate ($FeSO_4$). For one reason or another, not necessary to consider here, electrolytic precipitation of the gold from this solution of auric chloride ($AuCl_3$) has not been practised in the art. Electro-gilding, using gold anodes and various metallic objects as cathodes in an electrolyte consisting of auro-cyanide of potassium (KCyAuCy) in a solution of potassic cyanide (KCy), has been practised for about 50 years. Its details are too well known to need consideration here.

We will consider the subject in its bearing upon the obtaining of gold from auriferous rocks and ores. For this purpose the most important solvent in practical use at present is cyanide of potassium, measured by the production of gold from the mines by its means. It has been stoutly asserted that cyanide of potassium is not a solvent of gold, and more surely maintained that it is, by reason of its extensive use for the purpose, spite of the fact that pure solution of potassic cyanide in water will not dissolve gold at a practicable rate, if at all. If, for an experiment, we take a piece of gold leaf and lay it on the surface of a cyanide solution, we will find that it will there be dissolved in a few minutes (the stronger the solution the more rapidly), while a like piece sunk in the solution will be hours in dissolving, the strength of the solution affecting the rate but slightly. It is claimed, and justly too, that the presence of oxygen is necessary for the hastening of the solving action, or rather the combination of cyanogen with the gold, so that the resulting auric cyanide be dissolved. This fact was recognised upwards of 50 years ago by Elsner, and the chemical equation was expressed by him thus:

$$4Au + 8KCy + O_2 + 2H_2O = 4AuCyKCy + 4KOH;$$

the oxygen in this case furnishing the necessary element to decompose some of the potassic cyanide so as to form the double salt, auric-potassic cyanide and pottassic hydrate.

MacLaurin, a New Zealand chemist, has proved with mathematical precision the truth of Elsner's equation. His admirable research was published more than a year ago in the *Journal* of the Chemical Society, London, 1893, p. 724.

Gold leaf of the same thickness and very nearly the same weight was allowed to remain—

	In stoppered bottle. 92 hours	In openbottle. 68 hours	In bottle with O. 96 hours
Water	125 grm.	125 grm.	125 grm.
Potassium cyanide...	1 grm.	1 grm.	1 grm.
Gold	0·9947 grm.	0·99035 grm.	0 99425 grm.
Loss of gold	0·0018 grm. = 0·18 %	0 09175 grm. = 9·1 %	0 23995 grm. = 24·2 %

The minute quantity of gold dissolved in the stoppered bottle is apparently due to a small quantity of oxygen previously absorbed by the cyanide solution from the atmosphere. Just in the same way water, though not a solvent for calcium carbonate, will dissolve the latter to some extent if not previously freed from carbonic acid by boiling.

Recognising the apparent necessity of the presence of oxygen, many experimenters have tried many oxidising substances besides passing air through the cyanide solution—such as peroxide of manganese, ferricyanide of potassium, bleaching powder or other materials yielding chlorine, bromine, and iodine, peroxide of sodium. I have tried peroxide of hydrogen with success. All these are more or less effectual in hastening the solvent action; but, as they have to be added in quantities far in excess of the amount theoretically necessary to effect the reactions, if actually brought into contact with gold and nothing else, they are wasteful, because they decompose more of the cyanide than is necessary for solvent action. Bromine, chlorine, etc., are simply oxidising agents—secondarily, to be sure, but still decomposers of the cyanide in too great quantities, because they exert their action away from the particles of gold. These oxidising agents have been tersely called "cyanicides." Their actions, direct or otherwise, are practically those of oxygen.

Be that as it may, in practice the finely-divided auriferous rock, or ores, is submitted to the action of successive quantities of aqueous solutions of cyanide of potassium, containing varying quantities of oxygen, or oxygen-producing materials, or analogues, in large vats, as in infiltration and percolation. Each quantity of the solvent is allowed to remain for a greater or less number of hours in, and covering, the ore, and is then drawn therefrom into precipitation vats, where the gold is obtained from the solution by various means, which we will presently consider. Generally, the finely-divided auriferous materials are "tailings" from the gold-amalgamating mills, which crush and treat with mercury the material for obtaining the contents of gold by amalgamation as far as possible.

These tailings contain extremely fine-divided gold which has resisted amalgamation, and in varying quantities, averaging about five to six pennyweights per ton of tailings. Any economy in the above process, such as hastening the rate of solving the gold; prevention of decomposition, as far as possible and feasible, of cyanide; making the gold more easily and cheaply obtainable from the solution, etc., is of vast importance in the metallurgy of gold.

Looking at the matter from the electro-metallurgist's standpoint, some time ago I concluded that the action of oxygen was due to its strong electro-negative relation to gold in a cyanide solution. Therefore, I tried the effects of various materials which are electro-negative to gold in solutions of cyanide of potassium. Carbon in contact with gold in cyanide solutions forms with it a voltaic couple, and the gold is far more rapidly dissolved than when alone. The best practical application of this fact is to finely powder the carbon, and continually agitate it with the auriferous tailings in a cyanide solution. Though the finely-powdered carbon causes more speedy action than do a few, or more, large pieces, it is still an operation of chance, because the increased rate of action is dependent upon actual continued contact of gold and carbon until the gold is dissolved. Iron is electro-negative to gold in a cyanide solution. The two form a galvanic or voltaic couple, and the action is the same as in the case of the carbon, only less in speed, because the iron is not so strongly electro-negative as is the carbon. I have discovered that mercury is electro-negative to gold in a solution of cyanide of potassium. I have availed myself of this fact to improve the cyanide solvent after this manner: I add to the cyanide of potassium solution used for the purpose, in any of its strengths (which latter vary from 0·01 to 0·5 per cent. of cyanide), a small quantity of potassio-mercuric cyanide ($2KCyHgCy_2$), say, 2oz., or more, per ton of solution. The action is as follows: the electro-positive gold decomposes the mercuric cyanide, taking to itself the cyanogen thereof, and receives on its surface the liberated mercury which amalgamates it. Then in the solvent there is the contact of a voltaic couple, under which condition the electro-positive gold is dissolved, and afterwards the extremely attenuated film of mercury again dissolves in the cyanide solution, to react as before. There are no combinations, decompositions, and reactions taking place, except those noted as being caused by the voltaic couple.

There are no oxidations of cyanides to cyanates, which latter are not solvents of gold. The solving action takes place very much speedier, because the electro-negative material is brought into, and retained till dissolved in direct contact with, the electro-positive gold. There is no deleterious material introduced to the solvent, and the mercury acts as an assistant in the subsequent operations of obtaining the gold from the solvent. In the older process two, three, or more changes of the solvent were made, with intervals between, during which the oxygen of the air was permitted to permeate the mass of tailings, and thus furnish the necessary electro-negative material. By my electrolytic process the necessary electro negative material, mercury, is always present, so that the solution may go on uninterruptedly so long as the necessary solvent, cyanide of potassium, is present in contact with the couple. But in order to ensure this condition, especially with extremely weak solutions of cyanide, the use of which is desirable, the solvent must be kept in motion through the mass, so that the part containing the cyanogen constituent which should be in contact with the gold may continuously replace the solution which has acquired its quantum of gold.

Pursuing the above plan, extremely weak solutions of cyanide of potassium may be used—say 0·01 per centum, or less—by percolating them through the mass of tailings continuously, and simultaneously passing the solvent from the percolator through an electrolytic bath with sufficiently extended electrode surfaces, and enough amperes of current to ensure the electro-deposition of the dissolved gold from the solvent wholly, or in greater part. The solvent can be returned continuously to the tailings to dissolve more gold, if necessary; or, if practically all the gold has been removed, it may be passed to a fresh lot of tailings, to again be passed through the cycle of operations.

The most extensively pursued plan of obtaining the gold from auriferous cyanide solutions is by precipitation by means of zinc. Practice has demonstrated that for effective deposition the zinc must be finely divided, and its surface must be bright and metallic, free from oxide or salts. Therefore the "zinc shavings" are always freshly prepared before the time of use. They are put in boxes having bottoms of iron-wire netting, and these boxes are so placed in the precipitation-vat that the solution enters each box of the series through the bottom, up through the mass of

Digitized by Google

zinc shavings, down again, and up through the next box of the series. Having passed through the last box, much of the gold will have been deposited by auto-electrolytic action, and the solution, after being strengthened by the addition of more cyanide, is used to dissolve more gold, as before.

The electro-chemical action is as follows: The electro-positive zinc takes the cyanogen from the relatively electro-negative gold to form zinkic cyanide, which dissolves in the solution, setting free the gold in a finely-divided metallic condition. If the action would stop there this process would not be so objectionable. But owing to the voltaic couples formed by the zinc and gold, there is a further decomposition of the solution, with the formation of oxy-cyanate of zinc, zincate of potash, potassic hydrate, etc. Much of the deposited gold, becoming separated from electric contact with zinc, is redissolved by the cyanide, to be again deposited by more zinc. So it is practically impossible to precipitate all the gold by this means. If the necessary actions could take place in true electro-chemical equivalents, according to our table, 31·5 troy ounces of zinc would only be requisite to deposit 65·55oz. of gold. Instead of that, the practical amount, owing to the above-described wastes, and others, is about in the proportion of 1,750 troy ounces of zinc to obtain 65·55oz. of gold—over 50 times as much as should be necessary. There is something like a corresponding loss of cyanide of potassium. These wastes I have gathered from the data furnished by Eissler in his paper on the "Cyanide Process, etc.," read before the Institute of Mining and Metallurgy on November 21, 1894. Free alkali, or an alkaline condition of the cyanide solution, is desirable during the solvent action on the auriferous material; but it is undesirable in the zinc precipitation on account of its solvent action on the zinc, and its tendency to tarnish the zinc so that the auric cyanide may not readily act on it. On that account the smallest possible amount of alkali is used, when more would be desirable in the solving stage for decomposing metallic salts, etc., in tailings. When the depositing vats are cleaned up the precipitated gold is much mixed with pieces of zinc, insoluble zinc salts, etc. After careful drying, the zinc and gold slimes are treated by oxidising and smelting processes to secure the gold bullion, which is far from fine—say, 700 out of a possible 1,000.

With the object of overcoming the enumerated troubles, and other disadvantages, several experimenters have devised—on paper, at least—electrolytic processes for obtaining the gold from cyanide solutions. So far, the most successful one in extensive practice is that known as the "Siemens and Halske process," which is described in a paper read by Von Gernet before the South African Metallurgical Society some months ago, in the before-mentioned paper by Eissler, and one by Butters and Smart hereinafter noted. From these I gather the following facts: The cyanide solution is treated in four electrolytic vats, each measuring, approximately, 20ft. by 4ft. by 8ft., containing, alternately arranged, anodes and cathodes, which measure each 4ft. by 8ft., and are placed so that the solution in flowing through the vat moves downward on one side of each electrode and upwards on the other side, or are so arranged that the solution moves upwards by both sides of several electrodes, and downwards by a like number, serially, thereafter. The anodes are plates, or sheets, of iron, enclosed by canvas, and the cathodes are thin sheets of lead, supported in and by wooden frames. The current of electricity is caused by a dynamo taking 5 h.p. mechanically, and yielding 3½ h.p. in electrical energy at four volts pressure. (Von Gernet says four, Butters and Smart say 10, while Eissler says seven.) According to these data, the electric current may be $\frac{746 \times 3\frac{1}{2}}{4} = 652{\cdot}75$ amperes. The amount of iron used was 1,080lb. in one month, and the amount of gold deposited in that time was 697oz. 15dwt. 15 grains. The resulting products are the above amount of gold, some Prussian blue, ferric oxide, hydrogen, and an amount of impure litharge (PbO) from the cupellation of the lead cathodes; but nothing except the gold is of any economic value, because of the expense of reducing the other products to reworkable conditions. The facts about this process furnish an excellent text for a detailed consideration of the principles involved in the electro-deposition of gold. To begin at the beginning:

The Vat, or Depositing Vessel.—It is rightly made large, so that it may contain sufficiently extended surfaces of electrodes. It is made of wood, which sufficiently resists any deteriorating action of the electrolyte used in it. The electrodes are rightly arranged so that as the electrolyte passes through the vat, from end to end, it may come, as far as possible, into actual contact with the surfaces of the electrodes. Whether the surfaces are large enough depends upon the amount of electrolyte which passes through the vat in any unit of time, and whether, in its motion, it is brought actually, molecule by molecule, into contact with the electrodes. From the statement of the amount of gold—4dwt. 8 grains per ton of solution—remaining in the electrolyte after passing through the depositing-box, we may doubt the sufficiency of exposure to contact. The cathode surface is stated by Eissler to be 1,566 square feet. But, as it is evident from his other figures that he only took into account one side of the cathodes, the actual surface is 3,132 square feet. This is for one of four "precipitation" or depositing vats; so we have 12 528 square feet of lead surface, upon which were deposited 697oz. of gold in one month This statement of cathode surface agrees closely with that stated by Von Gernet and by Butters and Smart in a paper on the cyanide process read by the latter two before the Institution of Civil Engineers, February 19, 1895. The iron anode surfaces are $89 \times 7 \times 3 \times 2 \times 4 = 14{,}952$ square feet, from which we must deduct $7 \times 3 \times 2 \times 4 = 168$ square feet of surface of the end plates not presented to an opposite cathode. The anode and cathode surfaces are about 1½in. apart. On the whole, the mechanical construction of the vat and the arrangement of its parts seem to have been carefully considered, and to only err in the amount of electrode surfaces being too small for the actual electrolysis which takes place. The effective or commercial electrolysis is a very much less quantity, as we shall presently see. Von Gernet says that a better effect is produced by doubling the surface of electrodes than by increasing the current tenfold.

The Electrolyte is, of course, the solution of gold in a liquid composed of water, carrying also small percentages of potassic cyanide, potassic hydrate, and various compounds of cyanogen with metallic substances previously existing in the ore which had been treated by the solution, now the electrolyte. By the action of the electric current some ferro-cyanide of potassium is formed in the electrolyte, though much of this is converted into Prussian blue by contact with the oxide of iron formed on the iron anodes. The obvious improvement to be made is avoidance of any iron actions and reactions, because some of them consume electrical energy. The electrolyte is a weak solution at best, and, therefore, specifically, a poor conductor; but as the quantity is at all times large, the cross-section being 6,000 square feet, and length between electrodes but 1·5in., the resistance is practically nil, and need not be considered. The main consideration as to resistance to E.M.F. is that offered by the counter E.M.F. of polarisation. The oxide of iron formed on the anodes and in the pores of the bags drawn over them is, as a matter of resistance pure and simple, of some importance.

The Anode is composed of sheets of iron ½in. thick, exposing in the four vats 14,784 square feet to electrolytic action. Each of the 356 iron plates is "cased in canvas to retain the small quantity of Prussian blue produced (Butters and Smart), but also to retain the large quantity of ferric oxide produced. Von Gernet and Eissler state that the object of the "canvas is to prevent short-circuits" This last is an obvious precaution and result, owing to the close proximity of anode and cathode. We gather from the papers cited that an iron anode has been adopted after trying both carbon and zinc. Eissler says: "Carbon could be used as an anode, but it will not withstand the action of the current, and soon crumbles into a fine powder which decomposes cyanide. This finely-divided carbon is in suspension, and cannot be removed from the solution by filtration." Weightman states that he has "been using 'good arc lamp carbons,' and carbon in other forms, for the last six months, and they are still in excellent condition." Von Gernet says in his paper on the subject read last October before the South African Metallurgical Society at Johannesburg: "Zinc used as an anode forms a white precipitate of ferro-cyanide of zinc by the reaction of zinc oxide upon ferro-cyanide formed during the leaching. Similarly, iron anodes form Prussian blue by the reaction of oxide of iron and ferro-cyanide."

Let us consider these anodes. Owing to the fact that there must be an analysis (decomposition) of the electrolyte at the anode, electric energy is absorbed, or rendered latent, there; and if the material of the anode does not combine with the anion set free, to form a compound therewith, that energy is lost. Generally, and in this case, oxygen is directly or indirectly the anion, and as it cannot combine with a carbon anode, for instance, it escapes from the anode to the air as gas. The carbon anode is practically chemically unacted upon by the oxygen anion, but is mechanically disintegrated thereby, and the more rapidly the greater the current, and therefore of the escape of gas. Carbon is objectionable as an anode pure and simple, because of these two properties. But it is further objectionable because the oxygen, reacting on the potassic cyanide, forms potassic cyanate, which is inoperative as a solvent of gold. So, not only is the energy lost, but also the active ingredient of the electrolyte, making it inoperative as a subsequent solvent. Von Gernet's statement as to zinc is not clear. A very little ferro-cyanide should be formed during the leaching process. More likely the "white precipitate" is an insoluble coating of zinc oxy-compounds with cyanogen formed on the zinc anode. This coating offers great resistance to the E.M.F., so that it has to be increased to pass the necessary current; and this in its turn increases the difficulty, Much oxygen is set free, causing the corresponding wastes. So far, we now have only the iron anode to consider, as it has been adopted, and is used, at the mines. Practically, the iron anode is oxidised by reason of the current, and it takes a definite amount of electric current to oxidise a definite amount of iron; the iron-ampere-hour being 16·3 grains. The amount of iron used in the month of August was 1,080lb. This equals $1{,}080 \times 7{,}000 = 7{,}560{,}000$ grains. Providing this was all oxidised, the ampere-hours were $\frac{7{,}560{,}000}{16{\cdot}3} = 463{,}803$. According to Von Gernet, the amperes were produced by four volts; therefore there were in a month $\frac{463{,}803 \times 4}{746} = 2{,}487$ horse-power hours. The electric energy was 3½ h.p.; therefore was used $\frac{2{,}487}{3{\cdot}5} = 710$ hours, in a month of 31 days, or 744 hours—a curious coincidence. But Eissler says the pressure was seven volts, and Butters and Smart say the dynamo used gives 300 amperes at 10 volts. These latter statements, taken with the probable conditions that there are undoubtedly some wastes of iron in the way of unoxidised scrap, and possible intermissions in current, are probably nearer correct. Taking 300 amperes for 700 hours, we have an oxidation of iron $\frac{300 \times 700 \times 16{\cdot}3}{7{,}000} = 489$lb, and a scrap of waste of $1{,}080 - 489 = 591$lb. Evidently we need some more exact information for theoretical considerations. For this

Digitized by Google

current — assuming the minimum statement be correct — 300 amperes, the gold deposit was 697oz. 15dwt. 15 grains = 335,935 grains. According to our gold-ampere-hour equivalent of 38·1, this quantity requires 8,817 ampere-hours to deposit; but to do this $300 \times 700 = 210{,}000$ ampere-hours were expended—about 24 times too much, if the proper association of materials had been made so that all the economic actions went on in the electro-chemical equivalents to the gold. Upwards of 200,000 ampere-hours were expended in decomposing water and setting free hydrogen.

The Cathode is of sheet lead. It was adopted, according to Von Gernet, as best satisfying the following conditions: "(1) The precipitated gold must adhere to it. (2) It must be capable of being rolled out into very thin sheets to avoid unnecessary expense. (3) It must be easy to recover the gold from it. (4) It must not be more electro-positive than the anode, in order to prevent return currents being generated when the depositing current is stopped. The most suitable metal for the purpose is lead . . . and meets all the requirements of the case." These four requirements are very good, and should be, with others, carefully attended to. There is no exception to be taken to the first within practical bounds. To the second, we say the cathode should be as thin as is consistent with mechanical stability, and most assuredly as thin as possible when wasted absolutely, as it is in practice, at the rate of 750lb. per month, in a small plant. A far better cathode is one which does not deteriorate, and practically is not wasted at all. To the third, we say that it is not "easy" to recover the gold from the lead cathode. The necessary melting and cupellation is an expensive process—much more so than is the recovery of gold from the amalgam from a mercurial cathode, by distillation, or "retorting," as is continually practised in the metallurgy of gold. To the fourth, we say that a lead cathode is more electro-positive than an iron anode in a cyanide solution, and, therefore, does not fill the requirement. Furthermore, as soon as the lead cathode becomes coated with gold it becomes a gold cathode, which is electro-positive to the iron anode, therefore defective so far as this requirement is concerned. According to Von Gernet, a mercury cathode has been tried, but is impracticable on account of the large amount necessary to carry on the operation—say 80 tons to a small plant. "Sheets of solid metal (as copper) coated with mercury have also been tried, but have been unsuccessful, because the mercury, owing to the action of the current, will penetrate the copper and form a dry amalgam, which does not adhere to the plate." The mercury does not penetrate the copper plate any sooner than it does in the ordinary copper-plate amalgamation of the gold mills. That it forms a "dry" amalgam with the small amount of mercury which a vertically-placed copper plate will alone retain is evident. But the copper-plate cathode could be occasionally re-freshened with mercury by sprinkling to the extent of keeping the amalgam plastic, but not so thin as to run off. I prefer to furnish the mercury necessary on a copper-mercury anode by the direct electro-deposition of mercury with the gold from the electrolyte.

The Current.—This is variously stated by the different authors quoted as from 300 to 600 amperes with pressures of from ten down to four volts. Without unnecessary wastes, the current sufficient to deposit 697oz. 15dwt. 15 grains, equal to 335,935 grains, of gold in 700 hours is $\frac{335{,}935}{700 \times 38{\cdot}1} = 12{\cdot}6$ amperes. Von Gernet says: "In a fixed time a given electric current will deposit a certain quantity of metal, which quantity varies for different metals in direct proportion to their electro-chemical equivalents. This law holds good only for solutions strong in metal; but with dilute solutions, as in use in the cyanide process, the current does not find sufficient of the metallic compound present at the electrodes, and consequently decomposition of water also takes place. For this reason, to make the efficiency of the precipitation as great as possible, constant diffusion of the solution is requisite." This explanation contains the essence of the whole matter. The efficiency is only from $\frac{12{\cdot}6}{600} = 2{\cdot}1$ per cent., to $\frac{12{\cdot}6}{300} = 4{\cdot}2$ per cent. In most of industrial operations we would consider such efficiences exceedingly low. The waste of energy to produce the current, the waste of cyanide to produce Prussian blue, the waste of iron to make oxide and Prussian blue, the waste of lead to produce oxide of lead, and the waste of labour in handling these unnecessary quantities, add to the necessary expense of electrolytic treatment of auro-cyanide solutions at least £130 in a 3,000-ton per month plant, or 10·4d. per ton.

It will be asked, "Why these wastes, and can they be avoided without substituting others equally as expensive?" These expenses are due primarily and mainly to the improper selection of electrodes. The anode should be soluble under the electric current in the electrolyte in which it is immersed for at least two reasons: (1) that it may communicate to the circuit the energy due to the combination of the metal of the anode with the anion; (2) that the compound thus formed may be removed by the electrolyte to expose a fresh metallic surface for the continuation of the operation in regular progression.

Iron is not soluble in cyanide of potassium solutions. It is, as I have before stated, strongly electro-negative in such solutions to all other metals which may be met with in the operation. The anode should be electro-positive to gold. Copper is so, but it would enter the solution at the expense of the cyanogen. Besides, it would be deposited on the cathode after a time and render the gold impure. Carbon is not suitable, because in the cyanide it causes the formation of cyanate, and, besides, it is strongly electro-negative to a gold cathode. Zinc is electro-positive to gold in the electrolyte, but, as before stated, there forms upon it an insoluble coating impenetrable to moderate voltage of electricity. With iron it is necessary to raise the pressure of the current to overcome the resistance of the oxide and Prussian blue on its surface. But if it be arranged so that the anode be soluble, the current may be of very low voltage; and even it may contribute energy to the circuit. The way to secure this desideratum is to provide an electrolyte for the anode which will promote its solution. To do this, the selected electrolyte must be mechanically separated from the cyanide electrolyte. This can be done by the use of porous cells, such as are used in various of the forms of galvanic batteries. The electrolyte in the porous cell, for convenience called the anode-electrolyte, must be of such a composition that the accidental mixture of it with the cyanide solution, for convenience called the cathode-electrolyte, will not injure the latter, nor confer upon it deleterious qualities. Such an electrolyte is found in aqueous solutions of ammonium salts, such as the chloride, bromide, and sulphate of ammonium. Zinc or iron anodes placed in such electrolytes, in porous vessels immersed in the cathode electrolyte, will be readily dissolved, by reason of the formation of soluble double salts of the metal with ammonium.

With an iron anode in the cyanide solution it is necessary to raise the voltage to cause the current to pass the oxides, etc. In doing so there is an evolution of much free oxygen, with corresponding loss of electrical energy. But that is comparatively a minor defect. It also sets free a corresponding amount of hydrogen at the cathode. These two gases accumulate, each on its appropriate electrode, until their comparative levity causes them to escape against the pressure of the electrolyte. But they continually cover a very large part of the electrode surfaces, and thus keep from them the electrolyte, which should be in contact therewith. If this action be prevented, the electrode surfaces need not be nearly as large for the same amount of deposition of gold. In order to force the deposition, then, the voltage is raised to from four to ten volts, though one-quarter of a volt is sufficient to produce the necessary actions and reactions under proper assemblages of materials as to quality, size, and position. If the analysis (decomposition) and synthesis (composition) be equal, no energy is absorbed other than to overcome the resistance. As the resistance is small, owing to the large cross-section of electrolyte and small distance between electrodes, a very small E.M.F. is necessary when the proper electrode and electrolyte for it are used. Take such an assemblage, and the work of depositing 97oz. of gold should be done with the expenditure of $12{\cdot}6 \times 0{\cdot}25 = 3{\cdot}15$ watts, for 700 hours, instead of $300 \times 10 = 3{,}000$ watts for the same time.

If iron had been used in a proper electrolyte, the iron dissolved would have been as 65·5 : 28 : : 697 : 298oz. of 480 grains, equal to $\frac{298 \times 480}{7{,}000} = 20{\cdot}4$lb., in place of 1,080lb., a saving of 1,060lb. But iron would have used, say, about 40lb., including waste, of ammonium sulphate in the anode-electrolyte—worth about 55 pence.

If zinc had been used in a suitable electrolyte, the amount would have been 65·5 : 32·5 : : 697 : 345oz. of 480 grains, equal to 23·6lb., with a like consumption of ammonium salt. By the direct zinc precipitation in the McArthur-Forrest process, according to Eissler, there is a consnmption of zinc varying from 0·25lb. to 0·50lb. per ton of ore—say, an average of 1,000lb. for the quantity of gold produced (697oz.) from 3,000 tons of auiferous tailings. There is in this item alone a saving possible of £18 sterling per month.

In the *Proceedings* of the Engineers' Club of Philadelphia for November, 1894, there is a paper, entitled "The Electro-Metallurgy of Gold and Silver," by A. L. Eltonhead, in which he describes an alleged proces of separating gold from cyanide solutions, said to be used in a "small plant" by "the electro-chemical process (patent applied for) on the west side mine of the Tombstone Mill and Mining Company, of Tombstone, Arizona." The writer of the paper was evidently not fully posted as to the process. and did not mention the name of the "inventor" (?). The description is somewhat vague and imperfect; but we gather that the "precipitating-box is of novel construction," is 10ft. long, 4ft. wide, and 1ft. high, divided into "five lengthwise compartments." "Under each partition grooves may be cut, a ¼in. to ½in. deep, extending parallel with the partitions to serve as a reservoir for the amalgam, and give a rolling motion to the solution as it passes along through the four [*sic*] compartments. The centre compartment is used to hold the lead, or other suitable anode, and electrolyte." "The electrolyte may consist of saturated solutions of soluble alkaline metals and earths. The sides or partitions of each compartment dip into the mercury, which must cover the 'box' evenly on the bottom to the depth of about a ½in. Amalgamated copper strips or discs are placed in contact with the mercury, and extend above it, to allow the gold and silver solution of cyanide to come in contact. The electrodes are connected with the electric dynamo, the anode of lead being positive and the cathode of mercury being negative. The dynamo is started, and a current of high amperage and low voltage is generated, generally 100 to 125 amperes, and with sufficient pressure to decompose the electrolyte between the anode and cathode. As the gas is generated at the anode a commotion is created in the liquid, which brings fresh and saturated solution of electrolyte between the electrodes for electrolysis, and makes it continuous in its action." There seems to be a distinction between the "electrolyte" and the "solution of double cyanide of gold and potassium"; but where they are separated and how, if at all, does not appear. There is a "half-tone" picture of the "box," but it gives no more

Digitized by Google

information than does the above description. The anode surface is about 16 to 18 square feet, which can be made less by raising with thumb-screws. The cathode surface may be about 40 square feet. With a current of 125 amperes we should judge that "the gas creates a commotion," and such a commotion that it would be wonderful if the process be speedy, and otherwise than "continuous." From the principles involved, which we have considered, this "process" may be set aside. Yet it is but one of the many suggestions, or attempts, made by "inventors" (?) unacquainted with the electrical and chemical requirements. We have not the time to consider more of these within the limits of this paper. We know that oftentimes more is learned through failures than through successes, so we may consider these and the fallacies at some other time.

After thorough experimenting and test I have devised, and patented throughout the gold-producing countries of the world, the following described process for electrolytically obtaining gold and silver from auriferous and argentiferous rocks and ores: Sufficient solution of cyanide of potassium, of a strength varying from 2lb. to 10lb. of cyanide to each ton of water, with from 2oz. to 10oz. of a soluble salt of mercury, is prepared. The finely-pulverised ores, or tailings, are submitted to the leaching process with this solution, as in the other cyanide processes. The electro-positive gold in the tailings decomposes the mercury salt which comes in contact with it, and thereby produces voltaic couples of mercury and the minute particles of gold, thus hastening the solving of the gold. As the speed of solving is dependent upon the actual contact of the gold and mercury with the cyanide of potassium, it is preferable to keep the solvent in constant motion during the percolation, or leaching, so that fresh solvent, not exhausted of its cyanide, may continually be in contact with the gold. To accomplish this, the whole, or part, of the solvent is frequently drawn from the leaching-vats, or is continually passed through the tailings, until the solving action is completed. In this way much weaker solutions may be used than is the case where the cyanide solution is allowed to stand for long stated periods in the tailings. The weak solutions are preferable because the losses in material are not so great, and they are equally as good solvents as the strong, though not so speedy. As the solutions come from the leaching vats they are run continuously through electrolytic precipitating, or depositing, vats, constituted as follows: long boxes are provided, say, a little over 2ft. deep and 2ft. wide, containing copper plates 24in. square, and crossing the boxes every 1½in. to 2in., but placed so that every alternate plate rests on the bottom and sides of the boxes, and the intermediate plates are raised about ½in. above the bottom of the box. The number of plates and the length of the boxes are sufficient to permit of the deposition on them of all the metal constituents of the solution without so great a density of current that hydrogen is deposited likewise. If the solution be kept sufficiently in motion, the density may be 0·1 ampere per square foot of cathode surface; but as the solution becomes much weaker in metal towards the latter end of the vat or box, the density there cannot be so great. But this matter is self-regulating, because the greater tendency to polarisation impedes the passage of the current at the latter and weaker end. On the average basis of a density of current of 0·06 ampere per square foot, a cathode surface of 800 square feet is ample for a plant treating 3,000 tons of average tailings per month. One hundred plates of the size named supply this amount of surface. These plates are preliminarily amalgamated with mercury, and are each connected with a 'bus bar which is connected with the negative pole of the source of electricity. Between these cathodes are placed porous cells filled with a half-saturated, or other strength, aqueous solution of an ammonium salt, such as the chloride of sulphate. Into each cell is placed a rod, strip, or prism of zinc or iron, and each of these is conected by wire to another 'bus bar, which is connected with the positive pole of the source of electricity. The cyanide solution of gold and mercury is passed continuously through this vat, tank, or box, in a steady stream, and at a rate which ensures the deposition of a greater part of its metallic contents. If the quantity of mercury on the copper plates, together with that which is deposited from the solution, be not enough to keep the amalgam in a sufficiently plastic condition, more mercury solution may be added to supply mercury for that purpose. If it be too soft, the amount of mercury solution may be decreased. No mercury is lost, because recovered by the electrolytic deposition. Because the gold is deposited in exceedingly attenuated particles, the amount of mercury necessary to form with it a plastic amalgam is much in excess of the quantity of gold—say three or four times as much. This relations varies with the rate of deposition of gold. Take, for example, 12·6 amperes to deposit 1oz. of gold per hour, and 29 amperes to deposit 3½oz. of mercury in the same time, and we have the practical requirement of 41·6 amperes to deposit 1oz. of gold per hour. This for 744 hours per month is enough to more than deposit the 697oz. produced per month by the use of 300 amperes for the same time, in the case illustrated by the authors referred to hereinbefore. Because the anode is rendered soluble by putting it in a suitable electrolyte there is no consumption of energy in the actions which there take place. There is no escape of uncombined or free oxygen. A zinc anode is electro-positive to the mercury cathode to the extent of 0·25 volt—in itself sufficient to cause the deposit. When the anode-electrolyte has become exhausted as an electrolyte by the formation of double salts with the metal of the anode, the porous pots have their liquid contents removed and new electrolyte substituted therefor. Porous pots are used 1in. or so in diameter and 24in. deep; eight or ten in each space between the cathodes are sufficient. The cathode, though in its substance mainly of copper, is electrically a mercury one; therefore not as strongly electro-positive in its electrolyte as is a copper one. But the anode is sufficiently electro-positive to keep the cyanide solution from dissolving the gold and mercury when the dynamo or other source of electricity is unconnected, provided the anode and cathode be connected electrically. The depositing-vat can be, and is preferably, worked continuously. The anode parts are supplied from time to time as fast as dissolved. The anode-electrolyte is renewed from time to time, as necessary, by the use of a hand-pump. The amalgam is removed whenever desired from the cathode plates. For this purpose they can be disconnected from the 'bus bar one by one, removed from the vat readily, the amalgam scraped off, and the plates returned to the vat. There is, necessarily, no wholesale removal of electrodes, as, for instance, in the previous case, when the iron-plate anodes become full of ragged holes from corrosion, or when the lead cathodes were removed to be melted and cupelled. The amalgam is "retorted," as in the usual routine of gold amalgamation—a much simpler and less expensive operation than melting and cupelling. Practically no mercury is lost, but lead cathodes are lost. The E.M.F. necessary to carry out this process does not exceed one-half volt. Whatever there be more than that would be expended in decomposing the water of the electrolyte, thus unduly oxidising the anode, and setting free hydrogen at the cathode to no good effect, but rather cover the cathode with hydrogen films, and to that extent reduce the surface available for receiving the metal deposit, thus increasing the resistance and lessening the current. In the effort to increase the metal deposit by raising the voltage we would meet the same difficulty as is experienced with the said Siemens and Halske process, and find, as Von Gernet says, "a better effect is gained by doubling the surface than is obtained by increasing the current tenfold."

The expense of working 3,100 tons of tailings in August, 1894, at the Worcester Mill, in Johannesburg, by the Siemens and Halske process, as stated by Eissler, was, in detail, as follows:

	£ monthly.	d. per ton.
Filling and discharging leaching vats	125	10
Cyanide	75	6
Lime	15	1·2
Caustic soda	6	0·5
Lead	14	1·1
Iron	28	2·2
White labour	65	5·2
Natives' wages and food	20	1·9
Coal	57	4·6
Stores and general charges	41	3·2
Total	£450	3s.

By the improved electric process at least £130, or 10·6d. per ton, can be saved in expense in the following items: one-half of the cyanide, all of the lead and iron, 10 per cent. of the labour, and three-quarters of the coal. There would be wasted by the new process, say, 25lb. of zinc, worth at the mines about 19s., and about 5s. to 10s. worth of ammonia-salt—about 0·11d. per ton. The use of strongly-alkaline solvents is desirable during the dissolving stages of a cyanide process, because the alkali serves to decompose various salts and oxides, such as ferrous sulphate and oxide, ferric sulphate, and sulphates of aluminium and magnesium, etc., which would otherwise decompose the cyanide. But alkali is inadmissible when zinc precipitation follows, because of the increased waste of zinc caused thereby in the formation of zincate of the alkali. The alkali is inadmissible when chlorine, iodine, bromine, and such like "cyanicides" are used, because they expend their action on the alkali instead of where desired. By my electrolytic process the solvent may be very strongly alkaline without detracting from its desirable solvent action, but rather adding to its efficiency, and decreasing what would otherwise be the solvent action on other constituents of the ores.

At last night's meeting of the Institution the following candidates were balloted for:

Associates.—Henry Pem Bonus, 4, Claremont-gardens, Surbiton; Herbert Edward Keen, 21, Broad-street, Worcester; Joseph Ernest Petavel, 60, Kensington Gardens-square, Bayswater, W.; Robert Edward Phillips, M.I.C.E., 70, Chancery-lane, W.C.; Mansingrao Apasahib Solasker, 8, Zetland-terrace, Lansdowne-road, Old Charlton, Kent; William John Thomas, 3, Park-place West, Regent's Park, N.W.

Student.—Thomas Robert Robertson, 140, Douglas-street, Glasgow.

Discharge of Cargo.—The agents of the India General Steam Navigation Company, Limited, in Calcutta, bearing in mind the losses by fire occurring on steamers and flats, and with a view to minimise the risks run by working cargo on and off their vessels at night, have put in an electric light installation in their cargo godowns at Nimtollah, Calcutta. According to the *Indian Engineer*, the arrangement is such that the dynamos can be made to light any of the vessels working at night as well as the gangways and godowns. A Hornsby-Akroyd oil-engine supplies the motive power.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIV. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

SUPERHEATED STEAM IN ELECTRIC SUPPLY STATIONS.

The proper management of electric supply stations is a subject which might be very properly discussed, but it is far too large to be dealt with in a short leading article. The development of the industry has now attained such large proportions that a special series of volumes are needed which should deal, not only with the management of the plant used for producing the current, but also with the financial aspect of the question, and also with the status of the various companies from a municipal point of view. There is, doubtless, very much matter scattered in the technical press dealing with this subject, but there are as yet, so far as we are aware, no such facilities for acquiring information as to costs of management and upkeep as are to be obtained in, for instance, the gas industry. The latter is, of course, a much older branch, and its literature has gradually grown up round it, and possesses the advantage of experience gained over a much longer period. There is no doubt that the difference between the condition of dividend payment and non-dividend payment depends very greatly upon the ability and experience of the resident engineer. The plant may in the first instance have been well selected for its work, and the distribution system may be as nearly perfect as experience can make it—in fact, the consulting engineer may have left the station in thoroughly fit condition; but if the maintenance be faulty the station may be unable to pay a dividend.

Changes are taking place in many of the metropolitan electric supply stations. The St. James and Pall Mall Company are advertising their smaller plant for sale, with a view of replacing it by larger units; at Deptford a new dynamo and engine have been put down, larger than any in use there before—this unit was built by the firm of S. Z. de Ferranti and Co., and is probably now the largest in the world. One of the chief objects of the engineer is to reduce the height of the peaks in his daily load curve diagram, and attain, if possible, something approximating to a straight line. With all the energy, both personal and electrical, which has been thrown into the question of cooking by electricity and working small motors by the same means, these peaks have not yet shown much sign of diminution. It is, therefore, well worthy of consideration whether some means cannot be found to deal with the existing order of things without waiting idly hoping for the time when the ideal load curve will be attained.

At present there are many sources of loss. For example, during the winter months it is impossible to predict at what moment a fog may settle down over the district supplied from a given station; therefore extra boiler power must be available at any moment. Until recently very little attention has been given to the important question of economy in the boilers; if the engines and dynamos gave a high efficiency, it was thought that all had been obtained which it was possible to secure, but now attention has been directed to the great losses in coal consumption entailed by the necessity for keeping a

Digitized by Google

number of boilers ready to give off steam at a few minutes' notice. One of the most obvious methods of obtaining an increased output of steam for a short period is, of course, to force the boilers, but the unfortunate thing is that many types of boilers when forced give exceedingly wet steam, which means great danger to the engines, and if the methods of drainage for condensed steam on steam-pipes and engines are not perfect, there is a great risk of breakage of cylinders. If, however, some means can be found by which boilers may be forced and still give out dry steam, a great economy in coal should be possible, and certainly an increased efficiency obtained in the engines.

Superheating the steam is, doubtless, one method for effecting this economy, but upon this point a good deal of difference of opinion has hitherto existed, some persons maintaining that it is not possible to superheat steam without creating difficulties in the lubrication of the cylinder walls and in keeping the packing of the glands good. There are, however, various methods of superheating steam, and some of these are radically bad. We were led to consider this point by finding that for more than eighteen months past Mr. Patchell, the engineer of the Charing Cross and Strand Electricity Supply Corporation, has been experimenting with a system of superheating in the Babcock and Wilcox boilers at the supply station with very satisfactory results. The particular system employed is one which prevents the temperature of the steam being lower than the temperature due to the pressure in the steam spaces, and does not create the difficulties previously alluded to. We do not wish it to be understood that these boilers are worse than other boilers for causing priming when forced, nor do we wish to lay stress upon the particular method of superheating, but we firmly believe that very many stations which are now using a number of boilers as a stand-by during times of heavy load would find that their use might be discontinued if a suitable method of superheating the steam were installed. Such a system must increase the boiler power very greatly, and we commend the subject to the consideration of all engineers of central stations.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

PERMANENT MAGNETS USED AS MAGNETIC COMPASSES.

SIR,—In your issue of December 7, 1894, which has just come to hand, I read with some interest a descriptive account of the properties, etc., of a permanent magnet. I do not fear contradiction when I state there are few subjects known to scientific men that are less understood than permanent magnets and their source of power. It is the knowledge of this want of information that prompts me to subscribe this letter.

It is with the permanent magnet used as a magnetic compass that I propose dealing, and I hope, whatever may be said as to the merits or demerits of my theory, it will at least induce others to institute enquiries and make investigations as to the origin and source of the power that makes and controls the magnetic compass. The properties of the magnetic needle have been enquired into by men like Halley, Barlow, Faraday, and Walker, and to anyone who reads the works of these men it will be manifest that while they almost agree with one another as to the properties of the magnetic compass they differ considerably as to the source of the controlling power, or, rather, as to why a magnetic compass, when freely suspended, has a north and south seeking pole.

Among some of the theories set up was that the earth was either a vast magnet, or that there were large deposits of iron in the neighbourhood of the Polar regions. This latter theory was somewhat strengthened by Halley's discovery, or confirmation of discovery, that there existed on the earth's surface spots of equal maximum and minimum attraction to a magnet, or, in other words, that there were magnetic poles distinct from the earth's axis, and it was thought that this fact was consistent with the theory of iron deposits. About this time a careful examination of a series of experiments made with a magnetic compass in London showed that when a magnetised needle was freely suspended it was liable to several errors: (1) a horizontal variation of an almost constant quantity (slightly varying during a cycle of years); (2) a diurnal variation amounting to only a few degrees, but which was considerably affected by climatic and atmospheric changes; (3) a dip or tendency of the needle to assume a perpendicular position.

The only variation, however, which is taken into consideration in ordinary use of a compass is that first described above. All three kinds of variation are liable to considerable alteration in consequence of moving the instrument from place to place.

I have lately made a series of experiments with six needles, all most carefully made, measured, and weighed, and having on their north-seeking pole a vernier, and on the case of the instrument an arc, by which means I could read off any variation to a twelfth of a minute, or five seconds. All the needles were suspended on a single fibre of silk. I noted that no two of the needles would lie in the same meridian, some varying to the east and others west; while out of a series of changes and a series of observations covering several weeks, I found that on each series of observations the mean of the six needles was always the same. From these observations I came to the conclusion that there was some variation peculiar to each needle. Upon a subsequent examination of the needles, I found (1) that four of the needles were not of an equal hardness throughout; (2) that upon dropping fine iron filings on a paper over each of the needles, I found that the lines of force were in the case of the four needles more or less one-sided, showing beyond a doubt that there was an error in the needle, and on referring to my notes of observation, I found that the greatest magnetic difference was in the case of three of the four faulty needles.

As to the cause or source of magnetism, I must quote from Prof. Barlow's work, in which it is suggested that the action of a magnetic needle in having north and south seeking poles was due to a constant thermo-electric current flowing round the earth produced by the hot rays of the sun acting upon the molecules of the atmosphere.

Prof. Barlow made an experiment with a wooden sphere having a wire passed round its equatorial girth. Then passing a current of electricity along the wire produced an effect upon a magnet needle suspended over the sphere which was made to revolve on its own axis, as does the earth, with the result that he reproduced on his compass nearly all the variations to which it is subject terrestrially. I think that it may be reasonably claimed that if a current was at all times passing round the earth equatorially, all the variations of the compass would be fully accounted for. Though I agree with Barlow as to the presence of the current, I do not agree with him as to its source being due to heat of the sun. I rather choose the theory that the earth is to the sun what an armature is to a field magnet in a dynamo, and that the constant revolution of the earth against the heated surface of the sun sets up a current of electricity similar to that set up in an armature of a dynamo.

Let us assume that there is a current, however produced, passing round the earth's equator. Now, it is well known that electricity always passes along a conductor best able

Digitized by Google

and most suitable to carry it, and as it can be readily be understood how the earth's surface undergoes considerable alterations from season to season, month to month, week to week, and even day to day, so that part of the earth's surface, acting as a good conductor one day, may, by some climatic change, be made only an inferior conductor the next, and so cause the current to travel more or less out of a direct path. And this frequent change of the path of the current would account for the annual, monthly, weekly, daily, and even hourly change in the variation of a compass needle.

Now, as to what magnetism is, the writer of your article has suggested a theory of magnetised molecules, each being a perfect unit. This suggestion, far from being new, is the one most generally adopted—*vide* page 122, "Text-book of Science," 1874, by F. Jenkin, L. and E., M.I.C.E., etc. My own interpretation is that all substances are positively or negatively magnetic, and that all active magnets must have those two properties in combination. I will take as an example a rod of steel, and will describe it as containing a certain amount of latent magnetism, either positive or negative. And in order to render the rod an active magnet it will be only necessary to introduce into its composition an equal amount of opposite magnetism to that which it already contains, as by placing it near a fully-developed magnet or by rubbing it with one. Then what takes place is that the overflowing lines of force in the developed magnet passes into the steel rod and causes the dormant or latent magnetism of the rod to change into active form. And the longer the two are together the stronger will the rod become until it is developed to an equal degree, after which each magnet, being fully developed, will add to or sustain the power of the other until both are raised to a certain maximum.

The reason why the rubbing of one end of the rod with a magnet will cause it to be developed by an opposite force is that the rod had already a charge of latent magnetism containing all the elements of a magnet, but required the presence of either an excess of positive or negative force to start the whole into life. Consequently, when an excess of, say, the *north* or positive pole is introduced, its affinity is to attach itself to its reverse, and so create a south pole in the rod. Thus, once having developed in the rod a molecule of fully-developed magnetism, that molecule would at once transmit its now complete force to every other particle, until every particle in the rod was affected, and that being done they for all time counterbalance one another. And as both cannot act the same way at the same time, they take opposite ends or poles; and if there are no extremities, as in, say, a sphere, then there is no magnetism, because the latent power cannot find a suitable mode of dividing itself when separated from the magnetising magnet.

I will not say any more, as I think I have already occupied too much space, but I shall be glad some day to give you accounts of a number of experiments made by me and the deductions I draw.—Yours, etc.,

ARTHUR FOSTER SMITH.

Ludstone-chambers, 352, Collins-street, Melbourne,
February 2, 1895.

TESTING INSTRUMENTS.

SIR,—I note Messrs. Elliott Bros.' letter in your last issue. They make no reference to their attempted piracy of my patented apparatus, an additional proof of which I have before me in the form of a signed quotation for same. They, however, make an unfair and futile effort at a *tu quoque* reply, and taking one of several pamphlets issued by me, entitled "The Ayrton-Mather Galvanometer and its Accessories," they claim my wood-cuts (Figs. 5 and 6) as *their* original designs, without mentioning that these represent an ordinary wooden scalestand and shunt-box. These, as they naïvely admit, have been well known for 25 years. Indeed, they have been manufactured by all makers of testing instruments.

Though Messrs. Elliott Bros. were informed on the 4th inst. that my list No. 2 of 1892, being out of print, could not be sent them, their letter is so worded as to create the impression that they are criticising my general list. I told them that I hoped shortly to forward them copy of my new catalogue, for which some 60 or 70 original wood-cuts have been prepared, chiefly of instruments designed or perfected during the last few years.

I can assure you I have the greatest horror of flattering them, as they suggest, by any imitation of their methods.—Yours, etc.,

ROBT. W. PAUL.

London, March 9, 1895.

WHAT IS HEAT?

SIR,—My attention has been drawn to your review of my book in your issue of the 1st inst. As I feel that you have unconsciously done me some injustice, will you allow me to correct the mistake? Your reviewer states, "We must also suggest that in this book are many statements, which are not proofs, and the author is as dogmatic as any of those he criticises." Your reviewer has evidently overlooked the following statement in the book (page 37), which is the key to the position I have assumed. I feel sure that you will exonerate me from being dogmatic after your attention has been drawn to the sentence:

"As we can obtain, therefore, no real help from the metaphysician or mathematician, we proceed by other methods. We shall endeavour to give a graphic picture of the atoms and molecules, their physical constitution, their motions, and their general reactions. We shall propound an hypothesis, and shall assume that it is true, not that we wish to approach these great fundamental questions in a dogmatic style—this is farthest from our thoughts, but we have a very difficult task, and we have to bring the issues before the reader in the very clearest manner. This, we think, is best done in the way a barrister pleads his case in defence of his clients, and, like him, we shall assume our case is 'pure'—that it is the truth. We shall so state it, and we shall bring powerful evidence to prove that it is so, because we believe that it is the whole truth and nothing but the truth, and we shall place the onus upon our opponents to prove our case false. Although we shall for the sake of debate assume this position, we add it *is an assumption only, and the most we can say is we hope we have stated the truth.* We believe this: If we have not succeeded in stating the truth, we have done something to advance it, and this will be a gain."

Your reviewer acknowledges this result in these words: "This book contains much that is interesting, much that ought to lead to thought, much that is true, many very excellent and instructive experiments." Therefore all I aim at is achieved.

Then your reviewer twits me with falling foul of the mathematician. It was absolutely necessary I should do so. Of positivists, the mathematician is the most positive, and I found, practically, that if I had not introduced the fundamental errors in mathematics the reply would be: whatever is proved experimentally and is against mathematical ideas, mathematics can prove that in such cases experiment is false. And bear in mind I have been very careful to safeguard myself with quotations from the most able writers and thinkers. It is difficult to believe the trouble I have had to avoid the course I have most reluctantly taken. If I were to show you the evidence of contempt and repulsion given to me by the scientific world, you would cry shame against a set of men who pose as pioneers in the progress of human thought. Now, take the example of six objects multiplied one-half times, neither experiment can perform the operation nor the mind can grasp the operation. The view is not peculiar to myself, and this I show in the book. Thus Hall and Knight, in their "Elementary Algebra," state: "The definition of multiplication, in the strict sense of the word, supposes that a quantity is to be added to itself a certain number of times; but when the multiplier is a fraction, this definition ceases to be intelligible." The fundamental error arises thus: algebraists state a multiplied by b is the same as b multiplied by a. This fundamental error is very obscure or abstruse, but the effect of this error, I venture to believe, is far-reaching in the highest degree. Indeed, so much so, that I believe the detection of this error will revolutionise our ideas of Ohm's law: $C \times R = E$. This law, I think, will

Digitized by Google

be found not true, but the detection of the error will evolve a new law in similar terms to Ohm's law where the fundamental error is eliminated, and this can be experimentally proved. We then know what is electricity. I write very diffidently; I may be in error. I am working out the idea. All I can say is, so far the results are most encouraging.—Yours, etc., FREDERICK HOVENDEN.

Glenlea, Thurlow-park-road, West Dulwich,
March 11, 1895.

UNITED STATES PATENTS.

SIR,—It may interest those of your readers who apply for United States patents to know that on and after April 15 next the time for answering examiner's objections will be six months instead of two years, as has formerly been the case. This change will prevent the repetition of such cases as have been referred to in your journal, whereby patent applications have been kept from issue for many years in order to prolong monopoly. This alteration in the United States rules of practice is the result of the Government suit against the American Bell Telephone Company, which was reported in your columns at the time.—Yours, etc.,

pro J. G. LORRAIN (K. C. E.)

Norfolk House, Norfolk-street, Strand, W.C.,
March 7, 1895.

JERRY WIRING AND UNDERSELLING.

SIR,—Having seen a note in the current number of your paper that Mr. F. G. Baily was going to lecture on "The Scientific Principles of Electrical Engineering," on the invitation of a member of the Northern Society of Electrical Engineers, I thought I would avail myself of the opportunity, but arrived too late. I could not, however, help noticing some remarks made by one or two gentlemen during the discussion.

A question was asked, was there any known means of testing accurately "ampere-meters"? The chairman suggested that some consulting engineer present should answer the question. Whereupon a gentleman, after a pause, got up, and after describing minutely the wonderful instruments at Cambridge—not forgetting to thank the able lecturer, Mr. Baily, for his paper—went on to say that though that was not a place to discuss the lecture commercially, he should like to say one or two things on the commercial aspect of electrical engineering. He began by stating that electrical engineering was like the oil trade—that is, that there is a lot of roguery, or rather robbery, in both—and the only way to save ourselves from it was by educating the people, and consulting engineers on electrical matters. I asked my neighbour who was speaking, as I could not help but think how true his words were, and was told it was Mr. Ferranti.

In my own little experience—take, for instance, ship-work—I have been called a fool for giving all the information I could to engineers on board. Why? Because they get to know too much, and the next time the ship comes in he won't let you put in the time-sheet, "Wire broken, whole circuit gone," when it's only a loose contact in the main switch. That kind of policy is all very well, but I look at this way as the simpler. We can make electrical work the better for trade, and the more we can educate marine engineers and others on electrical work, it is better all round. It prevents disasters at sea, and when employed ashore I would much rather work under the supervision of an engineer who knows something about what you are doing than one who does not. Mr. Ferranti referred at length to the large amount of jerry work carried on.

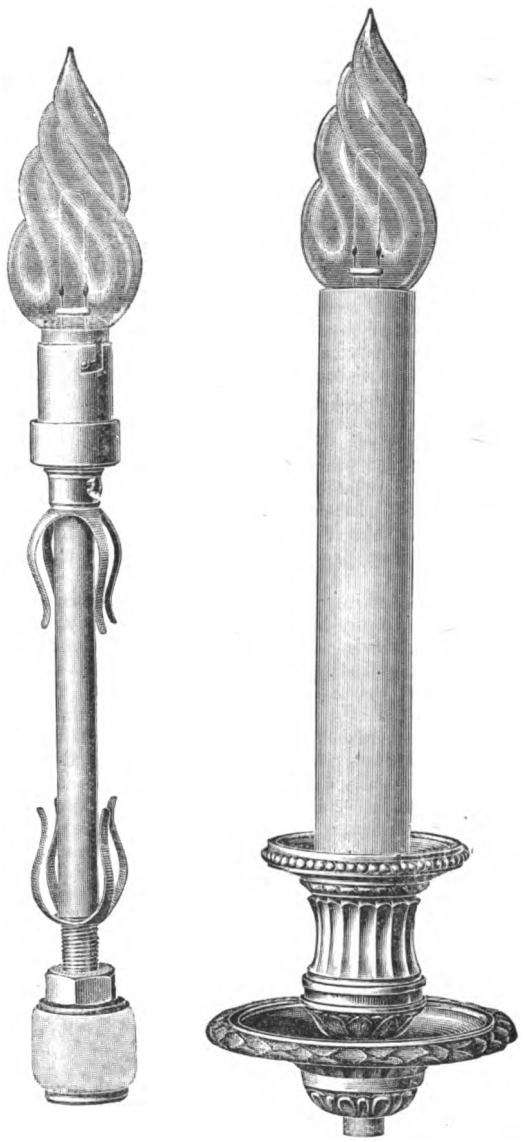
Kindly allow me to speak as a young contractor. I gave an estimate to a gentleman to fit up his shop with six lights at £1 per light, at the same time explaining I was running a risk in doing so. He gave me an order for two arc lights, but the incandescent lights he put over a day or two. Later, he hinted I was charging too much for the incandescent lights, and showed me a tender for the same work, material, etc., at 18s. per light, or, if an inferior class of work was done, 17s. per light. I told him it was impossible. However, he said he did not want to pull me down, and nothing more was done. I mention the latter more because my client was an honest man, but had not the slightest idea of what the electric light was as far as putting in an installation goes, or what it should cost. As for the contractor in question I have nothing to say, only the fact that he put in two prices is sufficient to condemn the principle, if not the man. I would do it properly or not at all, lay down what is a fair price and stick to it—no two prices. I may say the prices for fitting up lights in this neighbourhood vary from 10s. 6d. per light upwards.

In conclusion, I might say that there ought to be a society of electrical engineers throughout the country for the purpose of discussing and developing electrical engineering from a commercial standpoint.—Yours, etc.,

18, Geraint-street, Liverpool, CHARLES RETTIE.
March 11, 1895.

THE "STANDARD" SAFETY CANDLE FITTINGS.

The reduction in the price of incandescent lamps and their immediate accessories during the past year has resulted in more attention being paid to the adaptability of the electric light under circumstances in which its price has hitherto been an obstacle in the way of its adoption. Thus, the imitation candles



which formed an ornamental method of utilising the old-fashioned chandeliers have not been much used owing to their excessive cost, but a new era has commenced. Conical incandescent lamps can now be obtained at a price little, if at all, above that of the ordinary 16-c.p. standard, and as a consequence they are coming more and more into vogue. For this to happen without inconvenient short-circuits, etc., necessitated improvements in the methods of fixing and connecting up, and it is one of these improvements which we now illustrate. This device, which is due to Messrs. Meller and Lowry, is being introduced by Mr. T. G. Poole, of 88, Queen

Victoria-street, E.C. In the older style of candle fitting, the inner brass tube was supposed to be kept rigid by rubber rings fixed round it, but more often than not they were too small for the opal tube, and consequently had a loose appearance. In addition, the inner brass tube, being small, was used as the return circuit with only one leading-in wire—not at all a safe arrangement. The new arrangement is illustrated. It will be seen that a perfect fit is obtained in any size opal tube by means of the upper and lower metal springs, which can be bent in or out as desired, while the thickness of the rubber ring at the base is also adjustable by means of the small nut above it. The inner tube is of sufficient capacity to admit two leading wires, which can run right up to the holder. This also is small enough to slip into the opal tube, and yet will screw on to the brass tube, and, of course, can be either Edison screw or bayonet joint as required.

ELECTRICAL TRANSMISSION OF POWER IN SHIPYARDS AND ON BOARD MERCHANT STEAMERS.*

BY W. CARLILE WALLACE.

Mr. Thomas Richards, in his presidential address to the North-East Coast Institute, instances as a fact of great importance to large users of power that Messrs. Dorman, Long, and Co., of Middlesbrough, had on some of the outlying originally steam-driven machinery, substituted electric motor driving, the current for these motors being supplied by a 50-h.p. dynamo driven by an ordinary horizontal engine, with the result that a saving of some 30 tons of coal per week was effected, besides dispensing with two Lancashire boilers and the necessary attendance. It at once occurred to the writer that in no class of work more than in shipbuilding would benefit result from electric motor driving, and with this idea in view he at once set himself the task of finding out as far as possible what had been done in this direction, and this paper is to some extent the result of these investigations. After the very clear explanation of the principle of the dynamo and electric motor given by Mr. Mavor in his paper, it is unnecessary to enlarge on this subject. It may be accepted as an indisputed fact that for long distances transmission of power—say, two or three miles—no other system can compete in point of economy with electricity having a high E.M.F.; but in the case before us we have a totally different problem to deal with—namely, the transmission of power for comparatively short distances, say 300 to 400 yards, the current used being of comparatively low tension, probably not exceeding 120 volts, so that the same generating plant can be used for lighting purposes. Further, the loss by leakage through imperfect insulation is very much less than with high-tension currents; naked overhead conductors can be used, and there is no danger to life—in fact, as far as the latter point is concerned, as long as the E.M.F. does not exceed 500 volts, the effect of the current passing through the body would not be fatal.

The condition of things that at present obtains in a shipyard, as is well known to my hearers, is this. There are a number of punching and shearing machines, bending rolls, and machinery of this class placed in light sheds, and for the sake of convenience, partly because the work of these machines is intermittent, and partly because the shed is usually too light to carry shafting, these machines are driven by ordinary high-pressure engines, with cylinders about 8in. or 9in. diameter, and generally devoid of lagging. The steam is supplied from a boiler often a considerable distance from the machines, the steam-pipe in many instances running for some distance in the open air simply covered with non-conducting composition tarred to keep out the damp. Under these circumstances it is needless to say that the condensation is very great. We will take for example the case of a punch. The bulk of the work about a shipyard is, say, $\frac{7}{8}$in. holes in $\frac{3}{4}$in. plate, and the actual power required to do the work at the rate of 30 holes in a minute is about 3 h.p. to 3½ h.p.; but as the machines laid down are usually capable of punching 1in. to 1¼in. holes in 1in plate (besides to provide for shearing, which may be carried on at the same time as punching), the cylinders are much larger than would be required for the average work: the result is that the steam is constantly wire drawn in ordinary work. The following are some tests (see table) carried out on a punching machine in the writer's works. The steam is taken from a boiler at 60lb. pressure, and is carried through a 5in. pipe for a distance of 300ft., where it supplies two machines, and then for a distance of 130ft., where it supplies four other machines; the punch experimented on was one of the two first supplied.

From this table you will see that the indicated power was about double the actual power required to do the work, or, in other words, the efficiency of the machine and engine was 50 per cent. You will notice that the drop in pressure from condensation, etc., was 14lb.; and taking all the facts of the case into consideration, the writer does not think he is overstating the case when he says that when doing average work, the engines driving the punches in shipyards generally are consuming from 80lb. to 100lb. of steam per 1 h.p., or from 160lb. to 200lb. per actual horse-power as required to do the work, and the same will apply to the rolls and every other machine about the yard driven by an independent high-pressure

* Abstract of paper presented to the Institution of Engineers and Shipbuilders in Scotland on January 22.

TRIAL RESULTS OF SHEARING AND PUNCHING MACHINE.—Boiler pressure 60lb.; valve-casing pressure, 46lb.; loss of pressure in pipe, 14lb.; engine cylinder, 9in. by 9in. For diagram, see Fig. 1.

engine when the work is irregular. Now, if instead of driving these machines by steam, we substitute electric motors, the current being supplied by a direct-driven dynamo and high-speed triple-expansion condensing engine fitted with some efficient controlling gear, supposing, for the sake of argument, that we require the same equivalent indicated horse-power delivered at the punches that the triple-expansion engine requires 15lb. of steam, and that the efficiency of the dynamo current and motor are collectively 75 per cent. (see table below), we get 15lb. +33 per cent. =20lb. as the amount of steam consumed by the engine to give an equivalent 1 h.p. at the motors.

Distances up to 500 yards should have an efficiency of 75 per cent., the loss of 25 per cent. being made up as follows:

Loss in main generating dynamo	7 per cent.
Loss in mains	3 ,,
Loss in motors	15 ,,

If the motors are all small, say under 8 e.h.p., the loss will be greater.

This alone gives a very fair margin to work on in favour of motor driving, but there is still another advantage to be gained—namely, that the efficiency of the triple-expansion engine is much higher than that of the separate engine on the machine, and that the horse-power given out by the motor much more nearly agrees with the actual power required for the work than is the case when a high-pressure engine is used. Through the courtesy of Mr. Selby-Bigge (who has made a special study of this subject) and Mr. Panton, general manager of Messrs. Dorman, Long, and Co., Middlesbrough, the writer is enabled to give you the results (see table) of the practical application of motor driving in the works of the above-mentioned firm, in which the machinery is of very much the same class as in shipyards. In this case the generating dynamo is driven by an ordinary horizontal engine of a not very economical kind, so that the results obtained speak all the more in favour of motor driving.

TABLE OF ELECTRIC MOTOR TESTS.

Description of machine.	Driven by engine capable of indicating	Replaced by motor capable of indicating	Voltage at generator.	Current taken by motor.	Voltage at motor.	E.H.P. absorbed in doing work.
Group of machines, as under:	Horse-power.	Horse-power.		Amperes.		
Two cold saws..... Two ending machines One sharpening machine	27	10½	120	70	115	10·7
Troughing straightening machine.....	14	3½	120	12	118	1·9
Double-ended punch, punching four holes, one side and one other	14	5	120	25	115	3·7
Straightening machine, all sections	14	3½	120	15	115	2·3
Straightening machine, biggest sections	16	3½	120	35	115	5·4
Cold saw, 26in. diam...	9	3¼	120	15-27	110	2·2-3·9

If we examine this table of motor tests we will see that it bears out to a large extent what the writer has said with regard to the size of the engines fitted to this class of machinery; roughly speaking, the power which the engines in column 1 were capable of indicating was about three times the electrical horse-power absorbed in doing the work, as shown in column 6. Further, from column 6 we are enabled to tell exactly what consumption of steam on the main engine is required to do the work at the motor. Thus the efficiency of a triple engine combined plant—that is to say, the efficiency of the engine and dynamo taken together under full load—would be about 80 per cent.; and if this engine requires about 15lb. of dry steam per indicated horse-power the dry steam consumption per electrical horse-power would be 18·75,* the efficiency of the motor and circuit combined is, say, 75 per cent. (this has been taken low, as the motors are small—see Table IV.), therefore 25lb. of dry steam will give 1 e.h.p. at the motor. The evaporative efficiency of the boiler should be about 7lb. to 8lb. of water per pound of good Scotch coal, and when allowance is made for boiler and steam-pipe losses this should work out about 3·75lb. to 4lb. of coal per electrical horse-power. That the electrical horse-power is much more efficient for driving the machine than an equivalent indicated horse-power in the high-pressure engine cylinder is fully borne out by the results shown in the foregoing table of electric motor tests. It may be as well here to mention that Mr. Panton has informed the writer that so pleased is he with the result of the first installation that he is now putting down a further installation of 200 h.p. There is still a further advantage to be gained by the use of electric motors which it is hardly possible to estimate. The work of the machines in a shipyard is very irregular and intermittent,

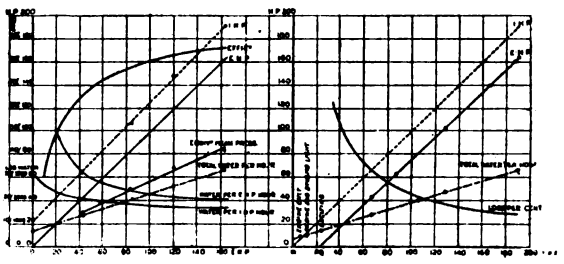

FIG. 2.

the machines sometimes requiring double the power to drive them than at other times, or one machine may be standing for a considerable time while work to a plate is being done in another machine; in the case of a motor the current which it takes is in exact proportion to the work to be done—when it stops the current absolutely ceases and no portion of the power to produce this current is required. It is far different when steam is used, for no matter whether the machines are running half-power or idle, condensation and leakage goes on just the same. Besides, to keep the cylinders clear of water it is necessary to keep the engines running all the time, generally at about 50 revolutions, and if we look back at first table we will see that this is equivalent to about ¾ h.p., which at 80lb. of

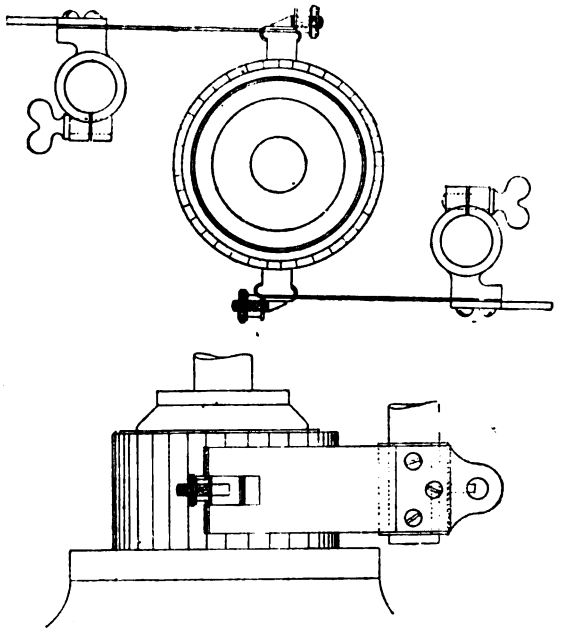

FIG. 3.

steam per indicated horse-power require 60lb. per hour, or as much steam as would be required to drive the machine electrically when punching ⅝in. plates.

TABLE IV.—Efficiency of Motors.

For 3-h.p.	motors	an	efficiency	of	78 per cent.
,, 5-h.p.	,,	,,	,,	80	,,
,, 8-h.p.	,,	,,	,,	84	,,
,, 11-h.p.	,,	,,	,,	86	,,
,, 16-h.p.	,,	,,	,,	87	,,
,, 20-h.p.	,,	,,	,,	87	,,
,, 40-h.p.	,,	,,	,,	89	,,

With regard to the cost of substituting motor driving for the present system, this would vary very much as to circumstances. The simplest way is that adopted by Mr. Panton—namely, removing the connecting rod of the engine and driving by means of a belt from the motor on to the flywheel of the machine (see

* Extract from Prof. Kennedy's report on test of Castle dynamo coupled to Willans's patent central-valve engine: "During the time when the condensed steam was being measured, the mean output was 1,010·5 amperes at 120·2 volts, which amounts to 121·5 kilowatts, or 162·8 e.h.p. The condensed steam amounted to 3,314lb. per hour, which corresponds to 27·3lb. per unit, or 20·3lb. per electrical horse-power hour. The indicated horse-power at the same time works out to 190·2, so that the combined efficiency of engine and dynamo (ratio of electrical output at terminals to indicated horse-power) reaches the very high figure of 85·6 per cent. The steam used per indicated horse-power hour works out to 17·4lb. All these figures represent, as will be seen, the working of the dynamo and engine at a load just below its nominal output, and he further works out the efficiency of the dynamo alone to be 95·6 per cent." (See Figs. 2 and 3.)

Fig. 4); the conductors will not be an expensive item if carried overhead. As some rough idea of what would be required in this way, a ½in. copper cable will convey about 25 h.p. 300ft. with an E.M.F. of 120 volts and a drop in pressure of about 4 per cent. Suffice it to say in connection with altering existing arrangements, the writer is given to understand that in 12 months the saving in coal, etc., paid for the experimental installation put down at Messrs. Dorman-Long's.

The cost of fitting up a new yard electrically driven should not greatly exceed the cost of the old system. The motors might be fitted on to the machine, cut or helical gearing being used instead of belt driving; the cost of conductors would be much less than that of steam-pipes; much less boiler power would be required; and instead of having separate lighting plant, the same generating plant could be used. It might be considered necessary in large works to divide the generating plant into two units, so that in case of a breakdown the whole work would not be stopped; but the likelihood of such a breakdown is very slight indeed, and as proof of this, a large power installation in Herstal, near Liège, has now been running for three years, and until recently the entire work depended solely on the running of a 500-h.p. dynamo and engine, both for light and power. About 2,000 hands are employed at the works; the large dynamo has never been the cause of cessation from work for a single minute. Once electricity is introduced on a large scale into our shipyards, other uses than those already mentioned will suggest themselves, as boring out stern tubes, hoisting, drilling on board ship, deck planing, etc.

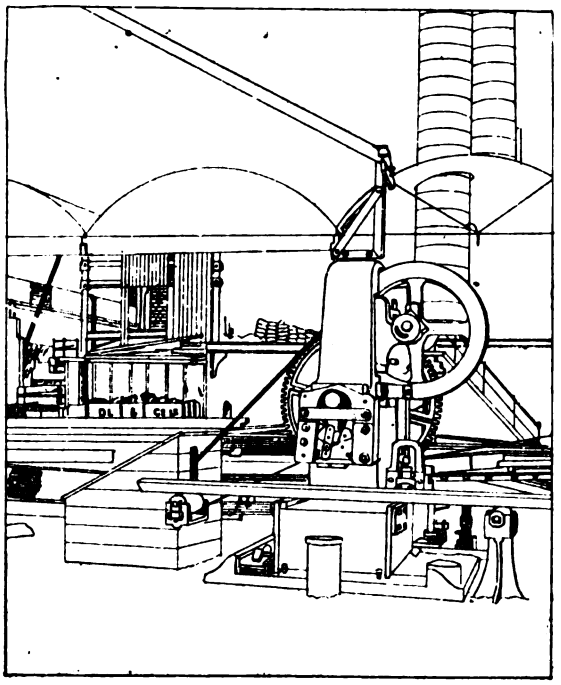

Fig. 4.

As regards wages, oil, etc., this would certainly be less than in the old system, fewer firemen would be required, the motors would require little or no attention, and, with properly arranged lubrication, very little oil indeed.* As to upkeep, of this the writer cannot speak from personal experience, but he understands that the upkeep on an electric power installation already running a number of years, and involving the use of a large number of motors and lamps, can be safely estimated at a little less than 5 per cent. The conductors will give much less trouble than steam-pipes, and there is really nothing about a motor to go wrong except the commutator; but since sparking has been reduced to a minimum, and the introduction of carbon brushes when higher tension currents are used (see Fig. 3), a commutator will run for years without renewal.

The writer might further go on to point out from actual data, that even in workshops and factories electrical transmission of power will compete favourably with shafting and belting, although at first sight this may seem hardly possible, but as this is rather outside the scope of the paper he will content himself with mentioning one or two cases in point. Some little time ago, Messrs. Siemens Bros. and Co. fitted up their works at Woolwich with electrical power transmission, and in the first 12 months they showed a saving of £1,200 over the old system in coal, oil, wages, and upkeep in a 1,000 h.p. installation. Then, if we go the Continent we have the National Arms Factory at Herstal, near Liège; the Royal Arms Factory at Liège; and the zincworks of the Vieille Montagne Company, near Jemeppe, all showing a distinct saving over shaft transmission. The writer thinks he has said enough to prove that electrical transmission of power is now beyond the experimental stage. He is speaking in the interest of economy. We have hitherto been far too lavish in the use of coal in our shipyards and ironworks. The East Coast is waking up to this state of matters, as is proved by what has been done by Messrs. Dorman Long, and Co., and Mr. Selby-Bigge is now busy fitting up the shipyard of Messrs. Furnace, Withy, and Co. with electricity. This yard will be entirely remodelled and driven exclusively by electric motors. He is also advising other shipbuilding firms on the same question. Are we on the Clyde to lag behind in the race? Let us look to our laurels, or, perhaps, when too late we may find we have lost a supremacy we can never regain.

Much that he has said with regard to the extravagant use of steam by punching and shearing machines will apply to the winches, windlass, and capstans on board ship, as also the steering gear, and as all these machines could be quite as well worked by electric motors and at less cost, the writer thinks it is high time the matter received the careful attention of shipowners, shipbuilders, and engineers. Consider the immense advantage it would be to get rid of winch-pipes on deck or along the side, with all the attendant evils of leaking joints, heat, and space taken up, and if they are placed below the deck a leak may damage cargo, or if passing through the passenger accommodation the heat may in the tropics make the rooms unbearable. Then, again, what an advantage in a passenger ship is the absence of noise, as an electrically-driven winch with properly made helical gearing will be noiseless as compared with a steam-driven winch. All our best boats are now fitted with electric light. We have electrically-driven fans for ventilation in many of them fitted by Messrs. Siemens Bros. and Co., and Messrs. Holmes and Co., of Newcastle. It is surely only a little step to enlarge the generating plant, drive it with the most economical class of engine, and work all the auxiliary machinery about the ship by means of motors. The French are now adopting electricity in their men-of-war for training the guns, bringing up ammunition, and all the work usually done by hydraulic power, and if electricity is reliable enough for this class of work surely it is reliable enough for driving winches, etc. Messrs. Siemens Bros. have made electrically-driven winches, and exhibited one at the Naval Exhibition in 1891, but whether any have been actually fitted on board ship the writer is unable to say. As to the cost of electric power installation on board ship, the first cost would probably be more than the present system, but the difference would not be very great, as the less cost of the conductors as against the copper pipes, covering stools, etc., would to some extent meet the extra cost of winches and generating plant, but the difference would be more than made up by the saving in steam and the advantages already pointed out.

* In respect to this, the Electric Construction Company, Wolverhampton, state that the motors in their shop fitted with automatic lubricators run for months without attention.

RAILWAYS IN NEW SOUTH WALES.

The Agent-General for New South Wales has sent us a copy of a supplement to the Railway Commissioners' Annual Reports, giving a short review of the policy adopted by the Commissioners in administering the Government railways and tramways. The Commissioners state that when they assumed office the interlocking of points and signals and the absolute block system of working had not made very great progress, and they determined to move forward with these important questions as quickly as possible. The system of block introduced for the single lines is a combination of the advantages of the "staff" system and the absolute block, known as "Tyer's tablet system" and "Webb and Thompson's electric staff system.' Both systems work excellently; the work and responsibility of the staff have been much reduced, and the traffic greatly facilitated and rendered more secure. For the express trains a system of exchanger has been adopted for the tablet, by means of which the driver can exchange the tablet when running at considerable speed, and the disadvantage of the single lines has been considerably reduced. The same system can be adopted with the electric staff. For outlying country lines a modification of the electric train staff has been arranged, so that if the traffic at any crossing station is too insignificant to justify having a person in charge, the guard of the train can exchange the staff without in any way interfering with the security of working. For working at night with through express trains this system enables staff economies to be effected by permitting of intermediate crossing stations being run through, by giving the driver a through tablet, controlling several sections. This system of working enables intermediate sidings to be opened without the provision of fixed signals, as the most perfect security can be arranged without them.

PHYSICAL SOCIETY.

A meeting of this society was held on the 8th inst., Mr. Walter Baily (vice-president) in the chair. **Mr. Naber** exhibited, and shortly described, a **New Form of Gas Voltameter.** The chief advantages claimed for this instrument are that either the oxygen or the hydrogen can be collected separately, and that the level of the liquid inside and outside the burette can be made the same, thus no correction has to be applied to the volume of the gas on this account. Variations in the temperature and barometric pressure are allowed for by reading an air thermometer, which is fixed alongside the burette. The inventor considers that this instrument will compare favourably in accuracy with the copper and silver voltameters now in general use Prof. S. P. Thompson considered that now so much care had been bestowed on the design of a gas voltameter, this instrument might issue into more general use than heretofore.

Prof. Minchen gave a short account of a paper by Mr. H N. Allen entitled "**The Energy Movements in the Medium Separating Electrified or Gravitating Particles.**" The object of the paper is to trace out the equi-potential surfaces and lines of flow for two electrified points or gravitating particles, and then to consider the paths along which the "energy cells" move when the charged points or gravitating particles either move towards or away from one another. By energy cell the author understands the small volume of the dielectric bounded by the walls of a tube of force and by two neighbouring equi-potential surfaces, which can be looked upon as containing a certain definite amount of energy. The author gives two figures showing the path of the energy cells (1) when the charged particles come together and meet, (2) when they separate and move off to infinity in oppo site directions. Using Maxwell's expression for the pressure along the lines of force, and the equal tension at right angles required by his theory to account for the attraction exerted by the sun on the earth, the author has calculated the energy density in the medium at the surface of the sun. The value obtained is 16 horse-power hours per energy cell. Hence, he concludes that at a distance from all gravitating bodies, an energy cell of ether contains at least this amount of energy. Prof. Minchin showed how by the use of polar co-ordinates the expressions given by the author could be simplified. He also gave a graphical method of obtaining the equi-potential surfaces for any configuration having given those for any other configuration. He pointed out that by a similar line of reasoning to that used by the author the energy per energy cell of the medium at the surface of Arcturus must be 8,100 times as great as at the surface of the sun, so that the minor limit given above by the author must be multiplied by 8,100 at least.

BRIGHTON CORPORATION ELECTRIC LIGHTING ACCOUNTS.

The accounts of the electric lighting department of the Brighton Corporation for the year ended December 31, 1894, have been issued. The expenditure during the year amounted to £40,840, and the total expenditure to December, 1894, has reached the sum of £119,382. We give below the revenue account and general balance-sheet.

REVENUE ACCOUNT, YEAR ENDING DEC. 31, 1894.

LEGAL INTELLIGENCE.

ATTORNEY-GENERAL v. ST. JAMES'S AND PALL-MALL ELECTRIC LIGHTING COMPANY.

In this case, which was decided on Tuesday before Mr. Justice Kekewich in the Chancery Division of the High Court of Justice, the Attorney-General, at the relation of the Vestry of St. James, Westminster, sought for an injunction to restrain an alleged public nuisance by vibration, noise, emission of gas, smoke, effluvia, steam, and hot water, caused by the works of the defendants, at their central station, in or near Mason's-yard and Duke-street, Piccadilly. The proceedings on the part of the Vestry were instituted under the provisions and powers of the Public Health (London) Act, 1891 (54 and 55 Vict., c. 76), Sections 13 and 21). One of the defences raised on the part of the defendants was that the acts complained of were justified by the terms of the provisional order by which they were regulated; but it was now conceded that, having regard to the decision of this Court (affirmed by the Court of Appeal) in the case of Shelfer *v.* the City of London Electric Lighting Company, and which it is believed will be the subject of consideration by the House of Lords, that defence could not avail. The case accordingly turned on the question of fact whether or not the acts of the defendants constituted a nuisance.

Mr. Warmington, Q.C., and Mr. Macmorran appeared for the plaintiffs; and Sir Richard Webster, Q.C., Mr. Fletcher Moulton, Q.C., and Lord Robert Cecil for the defendants.

Mr. Warmington had stated the case, and was proceeding to call the first out of numerous witnesses, when

Sir Richard Webster interposed, and terms of settlement were agreed upon similar to those which it was stated had been arranged in an action before Mr. Justice North, brought by the Windham Club against the present defendants.

Mr. Justice Kekewich by consent made an order that if, in the opinion of an engineer to be appointed by the Board of Trade or by agreement between the parties, the works of the defendants in Mason's-yard now caused, or hereafter should cause, any nuisance by vibration or noise, or by permitting to escape from the chimney shaft of the works black smoke, soot, ashes, or dust, or effluvia offensive and injurious to health, or by the discharging into the sewers of the Vestry of hot water or steam, the defendants would forthwith at their own expense make and execute all such works necessary for remedying the nuisance as the engineer should direct. The defendants were to pay the costs of the action and the expenses of the engineer, the costs of the enquiry before the engineer to be at his discretion.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY v. BRAZILIAN SUBMARINE TELEGRAPH COMPANY.

This action, which was heard before Mr. Justice Romer, was to restrain the defendants from reducing the telegraphic rates which had been fixed by what was called the "joint purse agreement." Under a subsequent arrangement the defendants had agreed to pay the plaintiffs £6,000 a year on the defendants extending their system. The defendants contended that under the altered arrangement the terms of the original agreement were varied so as to enable them to make a reduction in rates without special agreement with the plaintiffs or under arbitration, as provided by the original agreement.

Mr. Justice Romer held that there was no power to reduce the rates, and made a declaration to that effect, and he obtained from the defendants an undertaking not to reduce the rates except according to the original agreement.

SOUTH v. HARRIS.

In the Westminster County Court on Thursday of last week the case of South *v.* Harris was tried before his Honour Judge Lumley Smith, Q.C. It was an action by the plaintiffs, a firm of electrical engineers, to recover a balance of account in respect of electric light work carried out to the order of the defendant, who carries on business as a jeweller at Cranbourne-street, Leicester-square.

It appeared that a written contract was entered into between the parties by which the plaintiffs were to fit up the electric light throughout the defendant's premises for an agreed sum, and so far as the contract was concerned there was no dispute, but the plaintiffs now claimed for three extra lamps, which were fitted up to the order of the defendant, and were quite outside the contract.

The **Defendant** was called, and said he did not dispute that the work was done, but he contended that the price which was charged for it was excessive, and that 15s., which sum he had paid into court, was quite sufficient.

After hearing the evidence of the witnesses, his **Honour** said he was satisfied that the plaintiffs' claim was a reasonable one, and he therefore gave judgment for the full amount claimed, with costs.

COMPANIES' MEETINGS AND REPORTS.

HOVE ELECTRIC LIGHT COMPANY, LIMITED.

The third annual general meeting was held on Tuesday at the Cannon-street Hotel, E.C., Colonel H. Wood presiding.

The **Chairman**, in moving the adoption of the report and accounts (which were given in our last issue), stated that the progress of the Company continued in every way satisfactory. The sale of current to consumers had increased from £1,265 last year to £3,508, and the result of the past year's working had been a profit of £1,243, as against £77 for the previous 12 months. After deducting £563 for interest accrued on loans and debentures, there was a net balance to the credit of revenue account of £679. The directors proposed to write off £73 from the suspense account, and to declare a dividend for the year of 3 per cent. During the current year their customers had considerably increased, and it was evident that the profits would be larger than in 1894.

The motion was seconded and carried.

BIRMINGHAM ELECTRIC SUPPLY COMPANY, LIMITED.

The annual meeting was held last week at the offices of the Company, 14, Dale-end, Birmingham, Mr. Henry Buckley (chairman) presiding.

The **Chairman**, in moving the adoption of the report (which was given in our issue of the 1st inst.), said he was glad to tell them that during the past year there had been an increase of about 20 per cent. in the output of current, but he was still better pleased to say they had an increase in the number of consumers of something like 28 per cent. It was true that their average price per unit was not so large as last year, but that was partly due to the fact that motors were now beginning to be used, and the directors hoped that each year would see a considerable increase in that direction. Indeed, he was satisfied that would be so, especially when they were able to supply the jewellers' quarter, for where only ¼ h.p. or ½ h.p. was needed it was impossible to get anything more convenient or economical than motors. It would be seen from the accounts that they had amply earned, and more than earned, the dividend recommended in the report (4 per cent.). As to their proposal to carry forward £1,001 to next year's account, they felt that such a course would add materially to the stability of the Company, and they would, moreover, be undertaking a considerable capital expenditure in the ensuing year which to some extent would be unremunerative. They did not want to pay a decreased dividend next year, and he was satisfied that under the arrangement proposed they would be able to maintain the same dividend, or possibly to declare an increased one. The directors had quite made up their minds to reduce the price to consumers almost immediately, being of opinion that the increased demand which would result would more than make good the diminution of profit per unit. Since the directors last met the shareholders they had obtained from Parliament powers to enter the jewellers' quarter and an area at Edgbaston. They had therefore acquired the sites necessary for laying down distributing centres in Newhall-street and near the Ivy Bush, Edgbaston, but they would have sufficient room at the existing generating station to supply the demand during the next three or four years. It would be necessary for them shortly to call up the unpaid capital of £2 on their 10,000 shares; and in order to further strengthen the position of the Company, and to deal with the extension of business when the necessity arose, the directors recommended that the capital of the Company be increased from £100,000 to £200,000. In concluding, the Chairman said that in the opinion of the directors the concern was never in a sounder or more promising condition than it was at present.

Mr. Arthur Kean, in seconding, spoke in high terms of the manner in which the affairs of the Company had been conducted, but took exception to a proposal contained in the report that the new shares should be issued "at such times and on such terms as the directors may from time to time think fit." It appeared to him, he said, that the present shareholders should have an opportunity of taking those shares *pro rata* when they were allotted.

The **Chairman**, replying to a question as to the extent of the reduction in price proposed to be made, said the price charged now was subject to a sliding scale according to the amount of consumption, varying from 8d. to 6d., and the proposal was, though no resolution had been adopted, to reduce the scale to 7d. and 5d. With regard to the new capital they desired to raise, the idea of the directors was not to attempt to issue the whole of the shares at once, but to issue them in blocks, offering them first of all to existing shareholders. He should like to see them issued at a premium, to be applied in wiping out their preliminary expenses.

The motion was then put to the meeting, and the report was adopted.

The **Chairman** next moved: "That the capital of the Company be increased by £100,000, divided into 20,000 shares of £5 each

Digitized by Google

(making the total nominal capital £200,000), to be issued at such times and on such terms as the directors may from time to time think fit." This motion was, with slight modification, also passed.

Messrs. G. S. Albright and G. H. Johnstone were re-elected directors, and Messrs. Sharp, Parsons, and Co. auditors. The meeting closed with a vote of thanks to the chairman and Board of Directors.

IMPERIAL TRAMWAYS COMPANY, LIMITED.

The following is an abstract of the report for 1894 of the directors (Mr. George White, Bristol, chairman; Mr. Hugh C. Godfray, London; and Mr. J. Clifton Robinson, A.I.C.E., London, managing director) to be submitted at the thirty-second ordinary general meeting to be held at the Company's Offices, Clare-street House, Bristol, on the 16th inst., at 2 p.m.

Dublin Southern District Tramways Company.—The gross receipts of this Company are almost identical with the figures of the comparative period of 1893, though there has been a substantial saving in the expense for forage and the total expenditure being about £126 less, the net profit allows of a dividend on the £70,000 share capital at the rate of 2½ per cent., as against 2⅛ per cent. in the previous year. Since the last general meeting the Board have been constantly engaged in the negotiations relating to this undertaking, and have now the satisfaction of reporting the conclusion of a definite contract with the British Thomson-Houston Limited The works will include the reconstruction of nearly the whole length of tramways as double lines, in lieu of the existing single line with passing places, as well as the complete electrical equipment, including building alterations, generating and distributing plant, and motor cars. The scope of the contract has been extended to include the section from Kingstown to Dalkey (about two miles), at present a single line of 4ft. gauge, which will be relaid as double lines of the 5ft. 3in. gauge and equipped for electrical working uniformly as part of the through line from Dublin to Blackrock and Kingstown. The contract price is £109,200, to be satisfied by the payment of £10,000 cash and the issue of £30,000 5 per cent. debentures and £69,200 5 per cent. preference shares, both of the Dublin Southern Company. The operations have already been commenced, and it is anticipated will be completed in about four months.

Middlesbrough Tramways.—The tramway returns of this undertaking show a satisfactory increase of £226, though the boat receipts are not so favourable, and the expense of working the steamers includes some exceptional repairs. The net result is a profit of £363, equivalent to about 4½ per cent. per annum on the Imperial Company's capital involved.

Reading Tramways Company, Limited.—The gross receipts of this company are £133 higher, and the working expenses £63 more than for the corresponding half-year. The net increase enables the same rate of dividend—viz., 7½ per cent. per annum—to be maintained on the somewhat larger capital of £23,250.

General.—The net profits from all sources for the half-year amount to £2,687. 0s. 10d., as compared with £2,438. 5s. 4d. Adding the balance brought forward, the amount available is £2,818. 17s. 6d. Interest on debentures has already absorbed £449. 9s. 3d., and the directors have pleasure in recommending that the balance be appropriated as follows—viz., in payment of dividend on the preference shares at 6 per cent. per annum, £349. 16s.; dividend on the ordinary shares at the rate of 1½ per cent. per annum, £799. 13s.; addition to reserve funds for renewals and contingencies, £500; and carry forward to the credit of the succeeding account, £719. 19s. 3d. The Board consider it desirable to carry forward a larger unappropriated balance than usual, in view of the fact that the extensive interference with the Dublin Company's traffic will temporarily affect the revenue from that source. The directors retiring by rotation at the ensuing meeting are Messrs. Hugh C. Godfray and J. Clifton Robinson, and, being eligible, they offer themselves for re-election. The auditors, Messrs. James Fraser and Sons, also retire and are eligible for re-election. It is proposed to make the dividends payable on the 19th inst.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Eccles (Lancs.).—The Corporation desire by to-morrow tenders for an electric light installation at the sewage farm works, Peel Green-road, Patricroft.

Norwich.—The Town Council require by April 2 tenders for the supply of two Galloway boilers and the installation of electric light fittings at the new baths.

Manchester.—The Manchester, Sheffield, and Lincolnshire Railway Company require tenders by the 19th inst. for the supply, among other stores, of telegraph materials, tools, and oil.

India.—The Great India Peninsula Railway Company, with offices at 48, Copthall-avenue, E.C, invite tenders by the 21st inst. for the supply, among others, of galvanised iron tubes and miscellaneous wire.

Stowmarket.—The Urban District Council require by April 15 tenders for lighting the streets of Stowmarket from August 15 next to May 15, 1896, and also for lighting the post office clock. Particulars may be had of Mr. S. Prentice, clerk.

Bradford.—The Corporation require tenders by the 28th inst. for the construction and delivery of two steam dynamos. Specification may be had on application to Mr. Baynes, Electricity Department, Town Hall, Bradford, on payment of £1. 1s.

Derby.—The Corporation require by the 18th inst. tenders for the construction of three mild-steel Lancashire boilers and their accessories. Plans may be seen, and specification obtained, of Messrs. Bramwell and Harris, 5, Great George-street, Westminster, S.W., or of the town clerk, Derby, on deposit of £2. 2s.

Nottingham.—The Corporation invite by the 28th inst. tenders for two Lancashire steel boilers (26ft. long and 7ft. diameter) and fittings, and placing same on their seats at the public baths, Sneinton. Plans may be seen and copies of the specification obtained at the office of Mr. Arthur Brown, M.I.C.E., borough engineer, on payment of £2 2s.

Llanelly.—The Borough District Council desire by the 25th inst. plans, designs, specifications, and estimates of cost for the supply and installation of electrical plant and machinery, including street lamps and laying down mains. Plans of the district can be obtained from Mr. George Watkeys, C.E, borough surveyor, Llanelly. The plans, etc., are to be sent to the clerk of the Council before the 25th inst.

Worcester.—As will be seen from our advertisement columns, tenders are invited by the 6th of April for wiring the Victoria Institute. Copies of the specification may be obtained from the architects, Messrs. Simpson and Milner-Allen, 10, New-inn, Strand, London, W.C., accompanied by a deposit of £1. 1s. Plans of the lighting system may be seen at their offices, and on the works. Tenders are to be delivered at the offices of the architects.

Madrid.—The Electricity Supply Company for Spain, Limited, invite tenders for the supply and erection of certain machinery, etc., for the extension of their electricity works in Madrid. The plan of buildings and statement of requirements, with terms and conditions of tender, may be obtained at the office of the company, 15, St. Helen's-place, London, E.C., or of Mr. Robert Hammond, the consulting engineer, Ormonde House, Great Trinity-lane, London, E.C., on payment of £1 1s. Tenders must be addressed to Mr. P. A. Latham, secretary, by the 27th inst.

RESULTS OF TENDERS.

Ayr.—The Town Council have accepted the following tenders for the erection of the electric light station: mason work, Mr. Robert Hutchison, £3,303; slater and plumber work, W. Highet and Son, £356; carpenter, joiner, and painter work, D. and J. Milligan, £1,147; being a total of £4,806.

BUSINESS NOTES.

Ayr.—The Town Council have accepted tenders for the erection of the electric light station.

Western and Brazilian Telegraph Company.—The receipts for the past week were £3,639.

Wimbledon.—The Urban District Council have under consideration a scheme for lighting the town.

Portsmouth.—The Town Council decided last week to put down at the public baths an electric motor and centrifugal pump.

Tilbury.—The Parish Council have appointed a committee to consider the question of lighting the district by gas, electricity, or oil.

Salisbury.—The Town Council last week decided to discuss in committee the order obtained by the Salisbury Electric Lighting Company.

Hobart Tramways.—A meeting of the Hobart Electric Tramway Company was held on Wednesday at the offices, College-hill-chambers, E.C.

Chiswick.—The Works Committee reported to the District Council last week that the work at the electric light station was now proceeding satisfactorily.

Rothesay.—The Harbour Trust and Town Council on Tuesday met the Provost and Mr. Mavor, of Messrs. Mavor and Coulson, electrical engineers, with reference to the proposed electric lighting of the harbour.

Poplar, E.—The Poplar District Board of Works resolved last week that it was inexpedient for the Board to take any action on the subject of loans from the London County Council for electric lighting purposes.

Wells.—The Town Council have decided that the town shall be lighted by electricity. A concession for this purpose has been granted to Mr. D. Brown, and he has been given the public lighting at £350 per year.

Hammersmith, W.—The Vestry have decided to at once carry into effect the provisions of their electric lighting order by contract or direct The Electricity Committee are now considering carefully the latter part of the question.

Leith.—The arc lamp installation at Leith Docks and Harbour is rapidly approaching completion, and one of Heathman's extension ladders, mounted upon a spring carriage with 3ft. 6in. wheels, has been ordered for use of the lamp trimmers.

Debenture Issue.—The Chelsea Electricity Suppy Company, Limited, have this week offered for subscription £60,000 4½ per cent. debenture stock at £103. The stock will, after December 31, 1910, be redeemable on six months' notice at £110.

Eccles.—The Eccles Corporation have appointed Mr. Clirehugh, of Temple-chambers, Brazennose-street, Manchester, their consulting engineer for carrying out an electric lighting scheme. It is understood that an expenditure of about £20,000 is contemplated.

Digitized by Google

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 10th inst. amounted to £937, as compared with £687 in the corresponding week of last year.

Stair Treads and Manhole Covers.—The Safety Tread Syndicate, Limited, of 15, Barbican, E.C., and 101, Bothwell-street, Glasgow, have sent us a copy of their new catalogue of non-slipping stair treads, hydrant and manhole covers, coal-plates, etc.

Wigan.—The Gas Committee have referred back to the Electric Lighting Sub-Committee the question of deciding whether they think it necessary to engage a specialist on electric lighting to advise them on the schemes and tenders received by the Corporation.

Pipe Contract.—Messrs. Edward Le Bas and Co., of 49, Lime-street, E.C., inform us that they have just secured the contract for the whole of the lap-welded wrought-iron pipes required by the City of London Electric Lighting Company for their cable conduits, the delivery to extend over a certain time.

Partnership.—Messrs. Woodthorpe, Bevan, and Co., of Leadenhall-buildings, E.C., have particulars of a scheme in connection with which two gentlemen, who are engaged in enlarging an existing electric power station in America, are desirous of finding two or three others to join them in the enterprise.

City and South London Railway.—The receipts of the Company for the week ended March 10 were £971, against £930 for the corresponding week of 1894, or an increase of £41. The total receipts for the current period of the present half-year are £9,911, against £9,474 in the corresponding period of 1894, an increase of £437.

Perth.—It is stated that an action has been raised in Perth Sheriff Court by W. A. Bryson, electrical engineer, Glasgow, against the Magistrates and Commissioners of Crieff, and Provost Adie, as an individual, for £26. 5s., being fee and expenses for providing a report upon the Falls of Barvick water supply for the purpose of electric lighting in Crieff.

Acton.—The District Council last week considered a letter from Messrs. New and Mayne with reference to the electric lighting agreement, stating that they would be prepared to substitute 16-c.p. lamps instead of 10-c.p. lamps for general street-lighting, and in the main road to put in arc lamps similar to those at Ealing. It was decided to discuss the matter in committee.

Briton Ferry.—On Saturday at the Villiers Tinplate Works, Briton Ferry, the electric light plant was set in operation. Invitations were sent out by the engineer and contractor, Mr. Herbert Lewis. The engine was made by Messrs. Taylor, Struve, Eton, and Price, the dynamo by the Electric Construction Company, and the fittings by the Edison and Swan Company.

Birmingham.—The committee of the municipal technical school met on Monday, and decided to report to the Council that, having carefully reconsidered the matter of the tenders for the electric lighting plant at the new building in Suffolk-street, they can only repeat their original recommendation—namely, that the tender of Messrs. D. and G. Graham, of Glasgow, be accepted.

Llanrwst.—The Guardians had under consideration last week a letter from Messrs. Gower and Jones, Trefriw, asking whether the Guardians would exchange with them a piece of land running alongside the workhouse for another piece of land. The land was required for the purpose of laying down an electric tramway from Trefriw to Llanrwst Station. The consideration of the matter was deferred.

Sunderland.—The lighting of this town by electricity was formally inaugurated at the Town Hall on Wednesday of last week, when the Mayor turned on the current to the two arc lamps outside the Town Hall. The Town Hall is illuminated by 103 lamps of 8 c.p., 112 of 16 c.p, 68 of 32 c.p., and one of 300 c.p. The Doulton conduit has been used throughout for the accommodation of the mains.

Private Lighting.—Mr. Whiteley's establishment at Westbourne-grove and Queen's-road is having an extension of the electric lighting. Arc lamps are being fixed outside each of the shops, and a Heathman's telescopic tower ladder has been procured for attending to the lamps. Messrs. Jones and Higgins, the drapers at Peckham, have also purchased Heathman's tower ladder for arc lamp attendants.

Alderley.—Dr. Burgbardt, in moving at the last meeting of the Urban District Council the rescinding of the resolutions having reference to the electric lighting provisional order, criticised the action of the Council, and said he did not want the ratepayers to think they had finished paying as they had not been taken into confidence. He protested against the expenditure. Mr. Church seconded the motion, but it was lost on a vote.

Walsall.—The Town Council on Monday adopted a recommendation of the General Purposes Committee, that a resident electrical engineer, at a salary of £150 per annum, should be appointed to take charge of the electric lighting works. The Council also decided to acquire three transformer stations, and to make certain contracts, so that the Corporation may be in a position to supply the light in the coming autumn.

Lambeth, S.E.—The Lambeth Vestry last week received a letter from Mr. S. Morse stating that if the Vestry would appoint a committee he would be pleased to submit a proposal to them on behalf of the County of London and Brush Provincial Electric Lighting Company, Limited, for the transfer to the company of the Lambeth electric lighting order. The Vestry resolved to ask Mr. Morse to submit his proposals direct to the Vestry.

New Lead Accumulator.—Mr. Arthur Duffek, director der ersten Prager Elektrotechnischen Commandit Gesellschaft, 6, Ferdinand-strasse, Prague, announces that he has succeeded in constructing a new lead accumulator which surpasses all existing systems. The invention is patented in all civilised countries, and the foreign rights, as well as those for Austria-Hungary, are for sale. Persons interested are requested to address the owner of the patent, as above.

Brechin.—The clerk intimated to the Burgh Commissioners on Monday, that he had received a letter from the agent of the House-to-House Electric Supply Committee stating that their application for an order empowering that company to supply electricity to Brechin would be refused unless certain conditions in the agreement, to which the Board of Trade objected, were withdrawn. The Commissioners agreed to consider the subject in committee.

Worcester.—We are glad to observe that Mr. T. Caink, the city engineer, has issued a statement in self-defence in regard to the extras incurred in connection with the municipal electric light station, and for which he disclaims the responsibility sought to be put upon him by the Electricity Committee. The Board of Guardians last week adopted the report of the Building Committee in regard to the wiring of the male block and workshops now in course of erection.

Fermoy.—The Clerk mentioned to the Town Commissioners last week that Mr. C. J. Furlong, J.P., had informed him that a firm of electricians was prepared to erect the necessary plant to light Fermoy with the electric light provided it would be guaranteed that ultimately there would be a probability of 2,000 lights. The Chairman said he thought that if the scheme would pay a firm like that it should pay the Commissioners, and he would be in favour of their keeping it in their own hands.

Adjustable Swivel Bearings.—A card has been issued by the Unbreakable Pulley and Mill Gearing Company, Limited, of London and Manchester, illustrating their adjustable swivel bearings. It is claimed that by the adoption of this type of bearing a considerable saving in the power transmitted is effected as compared with the ordinary rigid bearing with brass steps, that the bearings run for years without attention, and that the long surface allows of the oil film to be maintained.

Blackpool.—The street electric lighting system is to be extended by the addition of three lamps in Church-street, three lamps in Talbot-road, and six lamps in Claremont-park. The minutes of the Electric Lighting and Tramways Committee, presented to the Town Council last week, mentioned that the tender of Messrs. Crompton and Co. had been accepted for two dynamos and one spare armature for the tramways department. Mr. R. Hammond's report on the motor commutator supplied to the electricity works was read at the same meeting.

Sheffield.—Sir Frederick Mappin, chairman of the Sheffield Gas Company, mentioned at a meeting of the company on Tuesday that the manager of the Sheffield Electric Light Company had written that if it is true that the Welsbach burners reduce the income of gas companies 50 per cent., it is difficult to understand the eagerness of gas companies to fix them. But surely, the chairman said, if they could give an article worth double the money it was their duty, and also their interest, to supply it, and they had pretty well found that to be so.

Electric Power in Mining Operations.—The statutory meeting of the United Pioneer Gold Mining Company, Limited, was held on Monday at Winchester House, Old Broad-street, E.C., under the presidency of Colonel Josiah Harris, who stated that the water difficulty had now been got rid of, as their crushing mills would be worked by electricity, the power for which would be supplied by the Moodies Exploration Company. Pending the erection of the necessary plant, they had been informed by their manager that they had sufficient water to supply a 15-stamp mill until the end of June.

Accrington.—The Legal and Parliamentary Committee of the Town Council have had under consideration the information received from other boroughs as to electric lighting stations, and the desirability of proceeding with or postponing the establishing of a station for the borough. It was resolved that the further consideration of the subject be postponed until the committee have received from the Manchester Steam Users' Association a special report on a new boiler being erected at Keighley on the "Livet" principle, whereby ashpit refuse can be used for the production of steam power.

Incandescent Lamps.—Mr. G. Straus, of 130, Queen Victoria-street, informs us that the fact of his having lately relinquished one of his agencies for incandescent lamps does not in any way interfere with his business. He continues to supply lamps as hitherto, and he has made arrangements to have a much larger and better assorted stock on hand for immediate delivery. Mr. Straus's works will, as heretofore, take care that no lamp is sent out without being tested, but as an additional guarantee to supply none but perfect lamps, he has arranged to have every lamp retested before leaving his warehouse.

Edinburgh.—The Town Council last week adopted a motion in view of the introduction of the electric light into the city, remitting to the Lord Provost's Committee to consider and report whether, and if so what, steps should be taken in the interests of public safety to secure that any faults in the gas-mains and service pipes shall be detected and removed without delay, and to provide against any dangers likely to result from insufficient piping. The Electric Lighting Committee of the Town Council on Tuesday provisionally fixed Wednesday, April 10, as the day for turning on the electric light in the city.

Bowness.—The chairman of the Urban District Council read a letter last week to the Council from Mr. D. Cloudsdale, asking

Digitized by Google

that more lamps should be put in on the road which had been constructed by himself and Mrs. Pritt and handed over to the Council. The Chairman said that then was the time for the Council to determine where new lamps, if any, were required. Once the bargain was made with the electrical company no extra lamps could be added. Every new street that was made was thrown upon the public to keep up, so the Council would be in order whether they put in or took up lamps.

St. Luke's, E C.—The Works Committee reported to St. Luke's Vestry last week that the clerk had submitted a letter from the engineer of the County of London and Brush Provincial Electric Company, Limited, of the intention of the company to commence the supply of electricity in the following thoroughfares: Finsbury-pavement, Cross-street, South-street, South-place, Finsbury-square, Worship-street, and Wilson-street. The Vestry decided to send to the Board of Trade a letter enclosing the resolution passed at a former meeting of the Vestry in opposition to the construction of transformer-chambers in the main thoroughfares of the Metropolis.

Sale of Plant.—The St. James's and Pall Mall Electric Light Company, Limited, announce that in consequence of the extension of supply from their central electric lighting stations necessitating the use of larger units of plant, the following machinery is for disposal by private tender: four sets of Willans i.h.p. and two sets of Willans "G, G." 80-i h.p. engines, coupled to dynamos by Messrs. Siemens Bros, and Messrs. Latimer Clark, Muirhead, and Co., suitable for modern electric supply on the low-pressure system. Communications should be addressed to the general manager and secretary, at the company's offices, Carnaby-street, Golden-square, London, W.

Nottingham.—On Friday night the effect of the complete installation of electric light in the Market place was witnessed for the first time. Since November four lamps, each of 2,000 c.p., have stood there Changes in the positions of the four have been made as the result of experience, and they now stand so that all the street approaches to the Market-place are illuminated to the best advantage. The additional four, which are of similar intensity, have been placed at the north and south sides, two lighting the Long-row and two the South-parade. Alderman Ford, the chairman of the Lighting Committee of the Town Council, switched the lamps on at seven o'clock. The Church of St. Thomas is now lighted by electricity.

Pemberton.—A deputation, consisting of Messrs. Gaskell and Sharrock, attended before the District Council last week to apply for the permission of the local authority to cross the highway by wires at any point deemed necessary, and to erect the poles on the highway for the purpose of carrying the aforesaid wires, and to put plant down in West Ward with the view of supplying the electric light. The deputation pointed out that it was proposed to put down plant to energise 300 16-c p. lamps. A plan was produced showing where the generating plant was to be located, and the direction in which the wires would be placed. The Council decided that the subject be considered at a further meeting.

Rye (Sussex).—The Rye Trade Association on Tuesday discussed the question of the Rye and Camber tramway. Councillor Hayles (the chairman of the company) stated that the company were about to close with a party as to the tender for constructing a permanent way. The cost would be about £1,200. The company were also in treaty as to whether the tramway should be worked by steam, oil, or electricity. The total cost would be about £2,000, and about £1,600 had already been subscribed. The President of the Association thought the company would want about £600 more before it was floated. It was a question as to whether it should be worked by petroleum or steam, as electricity, he opined, was impossible for them to attempt.

Bury.—Councillor Barr was in a jocular mood at a meeting of the Town Council last week. He stated that he hoped the Electric Lighting Committee were up to date, and making preparations for using calcium carbide, which, with a little water added to it, gave forth an acetylene. In answer to the Deputy-Mayor, Councillor Barr said this was a practical outcome of science, and by that means they would have light—not heat—units at a small cost. It was thought that electric light was going to do away with gas, but by the means he had suggested gas and electricity would go hand in hand, and the result would be more light at less expense. The new light would give 240 c p. as against 9 c.p. derived from the gas light.

Rustproof Iron and Steel.—Our attention has been directed by the London Rustless Iron Company, of West End-lane, West Hampstead, London, N W., to the Bower-Barff process for rendering iron and steel articles proof against rust. The process, for the working of which the company have laid down plant at the address mentioned, is applicable to pipes, iron gates, balconies, railings, culinary articles, etc. In a paper on rust preventives presented by Mr. M. P. Wood to the American Society of Mechanical Engineers at the Montreal meeting in June, 1894, the author stated that some experiments on a small scale of the Bower-Barff magnetic oxide application to pipes and iron exposed to electrolytic action appear to indicate its ample protective power.

Kingswood.—The District Council last week had an interview with Mr. Edwards, who attended from the Bristol Tramway Company, and requested the Council to sanction an extension of the double line to be laid down in Regent-street. The suggestion was acceded to. Mr. Edwards then asked the Council if they would allow the company to place the feeder wire under the footpath, which course was preferable to its being under the road. The Chairman mentioned that they desired to minimise the number of poles in the road, and he asked whether the tramways company could not utilise the electric light or telephone poles? In reply, Mr. Edwards stated that the design was for the poles to be placed on the opposite side of the road, as there was less traffic there.

Plymouth.—During the discussion on a proposed tramway extension at a meeting of the Town Council on Wednesday, Mr. Radford said that he understood that the Works Committee had under consideration the construction of electric works of some kind, and suggested that the experiment of electric traction should be tried on the Ebrington-street line. He was in favour of the extension of the tramway system in that direction, but urged that the substitution of electricity for horse traction should be thoroughly considered. Mr. Debnam thought it was very early yet to talk of adopting electric traction. It might be possible to utilise accumulators for driving the cars by electricity in connection with the electric lighting works it was proposed to establish. Meanwhile he suggested that the committee should not erect additional stables, but, if necessary, hire.

Wednesbury.—The Highways, Market, and Stables Committee reported to the Town Council last week that the Board of Trade had granted an extension of time for the use of steam on the South Staffordshire Tramways for one month from February 15. Mr. Oldbury, in submitting the report, referred to the appointment of a committee by the Council at their last meeting to watch the interests of the town in relation to the trams. Communication had been made with the Board of Trade, and the inspector (Major Marindin) who conducted an enquiry a short time ago at West Bromwich had strongly recommended the local authorities in that neighbourhood to consent to the electric system. He was pleased that such an issue had been arrived at. In consequence of that recommendation, they would probably keep their communication with Birmingham from Wednesbury and Dudley.

Shoreditch.—The Vestry have now adopted the report of the Electric Lighting Committee which was originally made in July last. The Vestry propose that Messrs. Kincaid, Waller, and Manville be employed as consulting engineers to carry out the electric lighting and dust-destructor scheme, the contractors for the dust-destructor cells preparing their own plans and specifications upon requirements to be specified by Messrs. Kincaid, Waller, and Manville at a commission of 3 per cent. on the amount of the tender accepted on the original specification, no commission to be payable on extras, such commission to cover the preparation of plans and specifications, except as above stated, and the superintendence of the whole of the work as engineers to completion and advising on the acceptance of all tenders The contractors for the dust destructor shall also guarantee a specified amount of steam, but the consulting engineers will be responsible for the successful execution of the whole of the work.

Weston-super-Mare.—The Urban District Council on Wednesday discussed a recommendation of the Lighting Committee in favour of electric lighting being introduced into the town. In moving the adoption of the minutes, the chairman of the committee (Councillor Deverell) reviewed the action which had been taken in the past with a view to the electric light being introduced. Mr. Medhurst, the consulting engineer, appeared before the Council, and stated that he had offered to the committee to enter into a five years' agreement with the Council in regard to the proposed scheme. He would run all risks during the five years, and would make good any loss which might accrue (previously depositing £500 as a proof of his *bonâ fides*), on the understanding, of course, that any profits which might arise during the term should fall to him. Councillor Dubin, as an amendment, moved that the question of introducing the electric light be deferred for the present. On being submitted the amendment was carried by ten votes to five.

Bradford.—It was mentioned by Mr. W. C. Dixon (chairman of the Gas and Electricity Committee), at a meeting of the Town Council on Tuesday, that in the electricity department there was a total income of £6,349 in 1894 as against £5,642 in 1893, and a gross profit of £3,512 against £2,876 in 1893. The cost of working the plant had been £2,836 against £2,765 in 1893. After deducting from the gross profit, income tax, interest on loans, and sinking fund, there remained a net profit of £1,449 against £1,179 in 1893. A depreciation fund had been started, and £1,062 had been put to that account, leaving a balance of £387 against £1,179 in 1893. This sum of £387, with the balance from the previous half-year, made the total profits unappropriated on December 31, 1894, £2,817. The units consumed were, in the 1892 half-year, 224,232; 1893, 272,874; and in 1894, 307,977. The cost per unit per ton of coal had been: 1892, ·454; 1893, ·743; 1894, ·541. The average cost per ton of coal and coke used had been: 1892, 7s. 10¼d.; 1893, 13s. 1d.; and 1894, 8s. 1¼d.

Tunbridge Wells.—For the first time since the prolonged frost operations were last week commenced in connection with the electric light scheme. The central electric light station and works are also being rapidly pushed forward in the Corporation yard. Dealing with the question of electric lighting at a meeting last week, the Mayor said reference had been made to the appointment of an electrical engineer, and in considering who should be appointed they wanted a good all-round man, and he was glad to say that there were some excellent candidates. As regards the extension of mains he hoped applications would be sent in to the committee, in order that they might have some idea as to what the demands for the light outside the compulsory area were likely to be. As regards the price, he was strongly against 8d. per unit. It might be said that he did not practice in the City what he preached here, but they had not the difficulties in Tunbridge Wells which they had to meet in the City. If they charged 6d. they would make the electric light a still greater success, because

Digitized by Google

more people would use it. The Corporation Lighting Committee have received a letter from Mr. Preece forwarding draft rules and regulations for house wiring, and a letter from Sir David Salomons with his observations thereon.

Hoole (Chester).—It was mentioned to the District Council last week by Mr. Duck that he had just seen the statement from the Chester United Gas Company, showing that the profits of the past year were something like £10,000. That was a handsome profit for a company to make, and he rose for the purpose, seeing that the Chester authorities were moving in the matter, of proposing that the question of electric light for Hoole should be referred to the Works Committee. The city was moving cautiously and wisely in the matter, and suggestions had been made that they should provide the light themselves. It was a great injustice that the Chester Gas Company should charge them 2d per thousand more than the Saltney Parish Council. Considering the splendid position they were in, they at least ought to put them even on the same terms as the city. Their Works Committee might also consider whether it was practical and advisable to provide the electric light themselves. Mr. Nightingale seconded, and the motion was unanimously passed. In answer to the chairman, Mr. Ewing (the surveyor) stated there were 70 lamps in the district.

Dublin.—The work of rebuilding the Southern District Tramway Company's line between Haddington-road and Dalkey was commenced on Monday under the superintendence of Mr. J. C. Robinson, managing director and electrical engineer of the company, and Mr Mossop, representing the British Thomson-Houston Company, Limited. The total estimated cost of the reconstruction and equipment of the line amounts to £109,200. Mr. August Krauss, of Bristol, has been entrusted by the Thomson-Houston Company with the construction of the permanent way. Ornamental steel standards will be erected on the kerbstones of the footpaths on both sides of the road opposite to each other, and 24ft. above the ground level will be suspended the cross or span wires from pole to pole. These standards will be placed at a distance of 125ft. apart along the whole line. Two trolley wires will be held in position by insulators from the span wires directly over the centre of each track throughout. The station for the generation of the electric power will be erected at Ballsbridge on the premises at present used as the company's horse car depôt. The new cars will be somewhat similar in pattern to those hitherto in use, but will be of more improved form and construction, having seating capacity for 50 passengers, 24 inside and 26 outside.

Newport (Mon.).—A question was asked by Mr. W. H. Brown at a meeting of the County Council on Tuesday as to when the borough would be put in possession of the electric light installation. Alderman Moses explained that the wet weather, followed by the month's frost, had tended to cause delay, and that the contractors, and especially the contractor for the large engines, were also behind. He hoped the works would be completed in about a month or six weeks; and that the day plant, providing for about 900 lights, would be ready in a week for those who were immediately in want of the light and for the Town Hall. The wiring of the Town Hall would be completed in a fortnight or three weeks. Mr. Mordey asked whether the foundations for the engines were ready, and, defending the contractor for the engines (a local firm), said there were other and strong reasons for the delay. Mr. Greenland hoped the committee would not be hurried over the electric supply, because it was very desirable that when a start was made it should be effective. He had been waiting some little time for the light at his establishment, but should be quite content to wait a little longer. Alderman Moses said the foundations were quite ready, and confessed that he did not understand Mr. Mordey's remarks about other reasons, and so forth. He had no other reasons he could give except what he had stated.

Burton-on-Trent.—In our last issue reference was made to the report of the Gas and Electricity Committee of the Town Council. Alderman Lowe, in moving the adoption of the minutes said the committee had received from the borough accountant a balance-sheet concerning the electric lighting during the past year. It was anticipated—at least, provision was made on the rate for it—that there would probably be a loss of £2,250. Of course they were all sorry to contemplate a loss so great as that, but he was glad to say it was much less, the actual figures being £1,802. 9s. 3d., so that they were better off by £450 than they anticipated 12 months ago. The working expenses for the year were £843 in round figures, while the receipts for electric lighting were £528, so that the actual loss on the working was £315. He had no doubt whatever that if they got as many consumers as they were able to supply with the electric light, there would be no loss on the general trade. What made the great difference was what was usually called the paying back of principal and interest on the loan; and he was afraid for some time to come, unless some cheaper way might be devised for producing the electric light, they might not be able to pay the dividend and redemption fund, though they might be able to pay the working expenses. Although they had the electric light, the consumption of gas did not decrease, but increased, and what was the most surprising was that it should have taken place after the price was raised.

Southport.—The minutes of the Electricity Committee presented to the Town Council on Tuesday contained a report from Prof. Kennedy with respect to arc lighting. Dealing with street-lighting, he said there was no doubt that the only satisfactory way of using electricity for this purpose was by means of arc lamps. In many instances, however, he had found that the cost of electricity in this form would be something like four times the cost of gas for a given length of street. On the other hand, the amount of light given by the arc lamps was more like 20 times as much as that given by the gas lamps which they replaced. The cost per lamp per annum would be something like £20, supposing that half the lamps were turned out at midnight, while the others burned until sunrise. After considering Prof. Kennedy's report, a sub-committee visited Portsmouth to inspect the rectified-current lamps in use there. They expressed the opinion that these rectified-current lamps were perfectly satisfactory from a lighting point of view, and they recommended that Lord-street and the Promenade should be lighted by 40 electric lamps supplied with rectified current The committee resolved that the report and recommendation be adopted, and that the sub-committee be instructed to proceed with the work forthwith. Councillor Hesford moved and Councillor Todd seconded the adoption of the minutes. The motion was carried. Prof. Kennedy has also recommended the laying down of two direct-driven alternators, each of 100 units capacity.

Bristol.—The electric light is to be introduced in the cathedral. It is proposed by the Visiting Committee of the Bristol Lunatic Asylum to light the latter building by electricity. The Bristol Sanitary Committee had under consideration last week a report by the surveyor that under the first schedule the tramways company had submitted designs of the proposed posts for West-street, Clarence-road, and Lawrence hill, for the purpose of carrying the wires for the electric tramways. The company also asked that the iron junction-boxes, 18in. by 13in. and 48in. high, might be placed one in the west end of Old Market-street and one in Clarence-road, opposite Trinity Church. The surveyor reported that with regard to the boxes there did not seem any provision for them in the schedule referred to. In answer to Mr. Todd, the surveyor explained that one post provided for a lamp, which might be used for electric lighting, and the other plan dispensed with a light, but had ornamental ironwork. The Chairman said they had power to appoint someone to superintend the work on behalf of the Corporation, and charge the cost to the tramways company. It was agreed that the surveyor should confer with the Electrical Committee in order that provision might be made to look after the interests of both committees and to pass the plans. The Electrical Committee of the Corporation have instructed their secretary to ascertain the amount of support likely to be given if the electric light mains are carried through certain districts in time to be used next winter.

Keswick.—The Urban District Council last week received Mr. Shipp, the engineer of the electric light company. Mr. Shipp said the first question was as to whether arc lamps or incandescent lights should be put up. The proposition was that three arc lights, of about 500 c.p. each, should be erected, but he suggested that it would be better to have incandescent lamps. His directors were suggesting the incandescent lamps more for the benefit of the town than their own. Mr. Wood then read a letter from the directors of the electric light company referring to the undertaking, subject to the approval of those who were introducing additional capital into the company, to give three lamps to the town, and stating that they had been advised by the Hon. C. Parsons that such condition was altogether unheard of and an insuperable obstacle to the proceeding with the enlargement of the station. They felt the great difficulty in which this decision would place the company, and three of their directors had visited Newcastle to interview Mr. Parsons and Mr. Harvey, his solicitor, and they found that unless the Keswick Council would give their unqualified consent to the application for the provisional order, they would be precluded from assisting the company in enlarging the station and putting down plant necessary to ensure a constant supply of light to the customers. Under these circumstances the directors felt they must ask the Council to comply with their request, or they would have no alternative but to call their shareholders together with a view to winding up. Messrs Mumberson, Pape, Philipson, Milburn, and Highton were appointed a committee to go into the matter.

Chester.—The Town Council had brought before them on Wednesday a recommendation from the Electric Lighting Committee that they should be authorised to accept the tenders submitted for engines, boilers, and dynamos, amounting to £8,518. Mr. W. C. Deeley, as chairman of the committee, brought forward the recommendation, but explained that he did not agree with it. He condemned the idea of accepting tenders from different people in consequence of the great difficulty of coupling different makes of machinery together. They ought to go to some well-known firm and get them to put up the whole system, and give a guarantee that they would run it for at least 12 months to the satisfaction of the Corporation. He complained that Dr. Hopkinson had disregarded the instructions of the committee in not sending out for tenders on the Oxford system. The committee had sufficient information which showed that electrical energy could be supplied at a less cost, or, at any rate, the same cost as the ratepayers were now paying for gas; but he thought that if the Council went in for a low pressure system without being able to carry it further than the compulsory area, they would be guilty of a great error. Mr. B. C. Roberts, in formally seconding as deputy-chairman of the committee, said the action of the committee was inconsistent, and their scheme was incomplete. In June last they passed a resolution that the electric lighting should be on the high-pressure system and all along it had been understood they were going in for the high-pressure generating system. Alderman L. Gilbert also condemned the scheme. He said that Dr. Hopkinson's system was to cost £22,000, while Mr. Preece had estimated that it could be done for £15,000. The Watch Committee, before the Electric Lighting Committee were called together, got 13 tenders, and only one of them exceeded £15,000. He moved as an amendment that the matter should be

Digitized by Google

referred back to the committee, with instructions to treat with some firm or firms for the lighting of the city, and, failing to make satisfactory terms, to bring to the Council plans, specifications, and tenders for a complete scheme, and that it should be an instruction to the committee that any firm or firms tendering shall undertake to run it for a given time. Mr. R. C. Davies seconded the amendment. The Mayor spoke strongly in support of the recommendations, defended Dr. Hopkinson, and pointed out that under his scheme it was possible to supply the light to the whole of the city. He asked the Council to trust the engineer they had called in, and leave to him the responsibility. The amendment was then put and carried by 21 to 9 votes. The Council then resolved to ask the Local Government Board to sanction the Council borrowing up to £25,000.

Yarmouth.—The borough surveyor (Mr. J. W. Cockrill) reported to the Town Council on Tuesday that the present amount of arc lighting in the streets would cost £700, as against gas £500 per annum. The public lamps were alight by the card 3,032 hours per annum, and at a charge of £700 the cost was rather more than 3s. 6d. per hour for all the lamps in the town. The lamps were alight 684 hours in January and February, and upon that basis the income was £185, including an item of £60 for 2,404 units supplied to customers at 6d., and the expenditure £243, showing a loss on working of £57. The items of expenditure did not include the cost of house connections and extensions, which would come out of the capital account. The customers were now being rapidly connected, and he had every confidence that the accounts would soon balance themselves, and show some signs of a contribution towards interest and repayment of capital account. Twelve additional customers had applied for 627 lamps, making the total number of lamps 3,095, and as the average earning power of each 8-c.p. lamp throughout the country was 10s. per annum, a sufficient number of lamps had been applied for to pay the whole cost of working. A fair estimate of the year's working was—income, £2,376, and expenditure, £1,710, leaving £666 available towards paying interest and redemption of capital. The Borough Surveyor stated that the borrowing powers of the committee would be exhausted before the present contracts were completed, and large sums were now being expended in providing meters, transformers, and additional mains, and that a considerable amount would be needed in the future The Council were recommended to apply to the Local Government Board for a loan of £2,000 for these purposes. The report was adopted.

Cardiff.—The Lighting and Electrical Committee of the Corporation met on Tuesday for the purpose of considering applications for the appointment of a practical man to take charge of the electric lighting station. The Mayor (Alderman P. W. Carey) presided, and there were also present Councillors T. Hurry Riches and W. Evans, Mr. W. Harpur (borough engineer), and Mr. W. H. Andrew (clerk). There were 38 applicants for the post, and out of this number the following were selected to appear before the committee: Wm. M. Huskisson, A.I.E.E., Ladbroke grove, London; Neville Applebee, Stafford-place, Buckingham Gate, London; Clement W. Sully, Burnham, Somerset; and Joseph Bastick, Granvilla-terrace, Chelmsford. The Mayor stated that these gentlemen would be asked to attend their ordinary meeting on Tuesday next. Councillor T. H. Riches said that he desired to say something about the present state of the electric light. He felt very sorry about the whole proceedings, and thought that serious steps should be taken to put the matter right. They had two valuable machines there which were rendered quite inoperative because the engines attached were inefficient. Then, again, they were spending £200 a year on these rectifiers, whereas if they had carried them to the station and put them on separate circuits they would have saved the interest on £5,000. The Mayor said that Mr. Riches must admit that all the new stations put up had gone in for rectifiers. Councillor Riches replied that that was so where they had been put up with an object in view, but these were not adapted to the rectifiers. At Portsmouth they were designed for the purpose. The Mayor said that they had got the best manufacturers of machinery in the world. Councillor Riches remarked that candidly he did not think there were better manufacturers than Messrs. Siemens in the world. They must not forget this, that Messrs. Siemens were to find certain plant, and they left their hands entirely free, but as far as the engines were concerned there were certain fads attached to it. It was no use running electrical plant on that system at all, unless they had a machine that could run it, and the sooner they took it off the better. The machines were not at all adapted to the work. To say that the system was wrong was absurd, with all due respect to the statements in the papers. The Mayor stated that rectifiers had been used successfully at Portsmouth, and been adopted at four or five stations recently put up. Councillor Riches said that if their electrical plant had been designed for the purpose it would have been all right. He was of opinion that it would be far better for the committee to alter the arrangement, and put down the plant as it should have been and settle it. They would save the wages of the men who had to look after the rectifiers. The Mayor did not know of any place in England where a more perfect light was going forth. The Mayor then referred to Mr. Massey, their engineer, saying that he was £1,400 out of pocket over the work. Mr. Riches said that Mr. Massey was an old friend of his, but he was bound to say what he felt was the truth, and he said it without wishing Mr. Massey any harm or without intending to offend anyone. He had been told that Messrs. Siemens were very vexed about the matter. Councillor Evans asked, if the rectifier was not of any service, had it not better be done away with? Councillor Riches did not want them taken away until Mr. Massey had tried experiments. Mr. Harpur remarked that a good deal had been said about this matter, but he felt very sanguine himself that it would come all right. In that morning's papers writers stated that they were not getting customers; but he would like to mention that they had already over 4 000 lamps wired at present, and were constantly getting more. He thought this exceedingly good. Further discussion followed, and ultimately the matter was adjourned to the next meeting.

The Rhondda.—In the course of a communication to a Cardiff paper on the proposal to light Rhondda Valleys by electricity, Mr. S. F. Walker says: The scheme I venture to propose will, I believe, commend itself to nearly everyone who will think the matter out for himself. The Rhondda Valley and its tributaries form one of the few districts for which high-tension alternating currents present special advantages. A single station might be established at the junction of the two valleys in the neighbourhood of the Cymmer Colliery, high-tension machines, furnishing alternating currents, with the necessary engines, boilers, and other accessories being laid down there. The high and low tension cables, the lamps for the public service, and the transformers might be carried on ornamental iron posts, placed on the sides of the roads. From the position I have indicated, cables could be carried on each side of the valley right up to Blaenrhondda, in the Rhondda Valley, to Maerdy, in the Rhondda Fach, down to the outskirts of Pontypridd, across to Ynysbwl, and up the Clydach and Dinas Valleys. In fact, the whole district could be easily covered. Two sets of posts might be fixed on each road, one set on each side of the road, each having its own supply cables leading right into the generating station; and the public service lamps would be placed alternately on opposite sides of the roads, so that all could not easily be extinguished together. The high-tension cables should all be insulated, and carried right to the tops of the posts, so that there would be very little danger of either leakage or shock from them; the low-tension cables being carried on the same posts, but well away from the high-tension cables, and also well insulated. If it was decided to provide a consumers' supply service also, the cables necessary for this could be added from time to time, as the demand increased, proper provision being made for them on the posts. A certain number of the posts also would be specially designed to carry the transformers, which would be placed well out of the way of both the careless and mischievous, carefully insulated and carefully protected from mischief, accident, and weather. If it was desired later on to run trams by electricity over a portion of the road it would be perfectly practicable to use the same poles for an overhead trolley service, with a modification of the plan so largely adopted in America; additional dynamos being laid down for the purpose, and other arrangements made that can easily be worked out when required. At the place I have named the coal consumed would be as cheap as if it were burnt at the several collieries, and if arrangements could be made to use the gases from a set of coke ovens, or from one of the blowers in the neighbourhood, to fire the boilers, the power would be obtained at a very cheap rate indeed. Water is abundant, and the engineer would not be troubled about the disposal of his ashes any more than the collieries are.

Brighton.—The Town Council last week adopted the statement of accounts which we published in our last issue. In moving the adoption of the Lighting Committee's report containing the accounts and recommendations, Councillor Stafford said he was very pleased to be able to report that the forecast which the committee gave some time ago was not exaggerated. The financial statement had been prepared by the borough accountant, and was vouched for as being absolutely correct. Those who had read Mr. Wright's exhaustive report as to the future price the committee should charge, would undoubtedly agree with the committee's resolution to charge 7d. for the first hour per day and 3d. afterwards. This would be a sweeping reduction, and would enable 87 per cent. of their customers to benefit by the change, whereas during 1894 50 per cent of their customers did not benefit by the reduction made. A very large number of their customers were tradespeople, who, on the average, used the supply two hours per day, and, therefore, in 1894 derived no benefit, but on the new scale their bills would be reduced about 28 per cent., private houses benefiting in like manner. Those using the light more than two hours per day would get a still further reduction, and he was satisfied that hotels would find the electric light from the Corporation much cheaper than any other system. The average price for electricity during the current year would not be more than about 5d. per Board of Trade unit. Congratulating the Council on the great success of the undertaking, Councillor Stafford said the committee visited the works in a body, and saw for themselves the admirable, careful, and profitable manner in which the undertaking was managed by their engineer, Mr. Wright, and were unanimous in their praise and satisfaction with his electrical skill and commercial ability—two qualifications not always to be found in one man. He unhesitatingly said that to Mr. Wright's able management and his system of demand and sliding scale charges were due the result of last year's working. He had absolute confidence in Mr. Wright's integrity and conscientiousness, and believed him to be above suspicion, and, therefore, had great pleasure in recommending the Council to increase his salary from £400 to £600 per annum. The enormous reduction in the price this year and the consequent increased load on the plant would, he believed, make Brighton the pioneer of cheap and profitable electricity, and ultimately enable them to offer the illuminant to the million as cheap, if not cheaper, than any other light. Electricity had never been produced at as low a total cost as the committee did in 1894—viz., 2½d. per unit—not-

Digitized by Google

withstanding the many stations having a very much larger sale, and their having to pay on the average nearly 21s. per ton for coal. Councillor Halliwell said the committee, in reducing the rental of the meters, was making a great concession, but he suggested that it would be a great boon and benefit to the concern if they abolished the charge altogether to consumers of over an hour a day. Councillor Costerton also suggested that there should be a stated charge for which consumers who believed their meters did not register correctly could have their meters tested or verified. He had been informed it might be done for 10s. 6d. Councillor Galliers said there was a fixed charge. Councillor Stafford, replying upon the discussion, pointed out as to the undertaking paying, that, in addition to the amount of the net profits, they had paid £2,351 to the redemption fund and £2,663 for interest. As to the suggestions of sweating, they paid the regulation wages and overtime, and he was perfectly certain that every man there was satisfied. As to the meter-testing, their rule was that in case of complaint a meter was examined, and if found to be correct, a fixed charge of 10s. was made, simply to cover the expenses; if the meter was incorrect, that charge was not made. As to meter rents, he pointed out that in the cases of certain small consumers they would have no means of making the undertaking pay if they did not exact a rental for the meters. He asked the Council, in regard to the recommendations now put before them, to have confidence in the committee, and the proceedings, on being put to the vote, were agreed to.

PROVISIONAL PATENTS, 1895.

MARCH 4.

4551. **Electrical cut-outs.** Ernest Alexander Claremont, Cooke-street, Hulme, Manchester. (Complete specification.)

4557. **Conduit electric railway.** Leonidas Calvin Pressley, 60, Queen Victoria-street, London. (Complete specification.)

4576. **Improvements in electric motors.** Archibald H. Brintnell, 323, High Holborn. (Complete specification.)

4577. **Improvements in or connected with apparatus for electrically lighting miners' safety lamps.** William Ackroyd and William Best, 33, Chancery-lane, London.

4593. **The pen's electric illuminator.** Henry William Cobb, 28, Hollyoake-road, Newington-butts, London.

4610. **Improvements in or relating to secondary batteries or electric accumulators.** Wilheim Alexander Boese, 6, Lord-street, Liverpool. (Complete specification.)

MARCH 5.

4623. **Electrical method of closing the air-exhaust apertures of hermetically sealed canisters and like vessels.** George William Davey, Bristol Bank-buildings, Bristol.

4660. **Improvements relating to the electro-deposition of iron on copper or other metallic surfaces.** Arthur Hiorns, 18, Southampton-buildings, Chancery-lane, London.

4670. **Improvements in electric apparatus for igniting and extinguishing gas jets simultaneously from a distance.** Oscar von Morstein, 89, Chancery-lane, London. (Complete specification.)

4672. **Improvements in telephone and telegraph systems.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Christopher Ambrose Shea and Freeborn Fairfield Raymond, United States.)

4685. **Improvements in commutator brushes.** Francis Henry Louis Blanken, 37, Chancery-lane, London.

4697. **Improved electric signalling apparatus for railways.** Gustav Adolph Lyncker and Anton Schropp, 18, Buckingham-street, Strand, London. (Complete specification.)

MARCH 6.

4716. **Improvements in and relating to phonographs and similar sound-recording and sound-reproducing instruments.** Horatio John Heinzie, 16, East-road, City-road, London.

4770. **Improvements in apparatus for measuring electricity.** Edward Howard Percy Humphreys, 55, Chancery-lane, London.

MARCH 7.

4851. **Automatic replacement fuse for electric lighting.** William Cole, 80, Franche Court-road, Lower Tooting, London.

4873. **Improvements in connection with electrical insulating materials.** Tressillian Percy Wiggins and George Herbert Wiggins, 36, Chancery-lane, London. (Complete specification.)

MARCH 8.

4939. **Indirect electrolysis.** Emile Androli, 47, Lincoln's-inn-fields, London. (Complete specification.)

4941. **Improvement in pushes for electric bells.** Richard John Dale, 60, Queen Victoria-street, London.

4979. **Improvements in wall plugs for electrical connections.** Henry Wilson Young, 1, Queen Victoria-street, London.

4980. **Improvements in dynamo-electric machines and motors** Llewelyn Birchall Atkinson, 1, Queen Victoria-street, London.

4987. **Improvements connected with arc lamps.** John James Rathbone and the "Harp" Arc Lamp Syndicate, Limited, 166, Fleet-street, London.

MARCH 9.

16156A. **Improvements in electric locomotives chiefly designed for use in mines.** Bruno Lebrun, 45, Southampton-buildings, Chancery-lane, London. (Date claimed under Patents Rule 19, August 24, 1894.)

5003. **Improvements in electric condensers.** Sebastian Ziani de Ferranti, 27, Charterhouse-square, London.

5004. **Improvements in apparatus for regulating and controlling electrical circuits.** Harold Dickinson, 25, Ella-street, Blackman-lane, Leeds.

5031. **Improvements in electricity meters.** Francis Fane Yeatman, The Island, Reading.

5041. **Electric steering gear.** Siemen Bros. and Co., Limited, and George Sylvester Grimston, 28, Southampton-buildings, Chancery-lane, London.

5058. **Improvements in or applicable to electric arc lamps.** Robert James Rae, 4, South-street, Finsbury, London.

5059. **Improvements in and relating to electric accumulators.** Alfred Oblasser and Charles Théryc, 45, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1891.

13503 **Electric machines, etc.** Von Dolivo-Dobrowolsky and others. (Second edition.)

1893.

21714. **Electric exchange systems, etc.** Williams.

1894.

7080. **Phonographs.** Oulton.

7155. **Electric cut-out.** Higgins.

7165. **Secondary batteries.** Clubbe and Southey.

7240. **Electrically-propelled vehicles.** Bersey.

8808. **Electric batteries.** R. McL. and A. McDonald. (Second edition.)

11069. **Submarine telegraph cables.** Muirhead.

1895.

545. **Electrical switches.** Dorman and Smith.

1000. **Electric railways.** Dulany and Shaw.

1088. **Electric fuses.** Siemens Bros. and Co., Limited, and Hird.

NOTES.

Hobart Electric Tramway.—It is stated that this electric tramway is paying well.

Personal.—Mr. Neville Applebee, of London, has been appointed electrical engineer-in-charge of the Cardiff central station.

Light and Heat Exhibition.—This exhibition, in consequence of the recent long-protracted frost, has been postponed for a few months.

French Cable.—A cable, 25,000 metres in length, has just been finished at Seyne, and will shortly be taken to Madagascar by the English chartered transport.

Lecture.—Prof. W. Robinson, M.E., delivered the first of a course of three lectures explanatory of "The Work of the Electric Current," at the Nottingham University College on Friday.

Lighthouse Illuminants.—A paper on this subject was read last week by Mr. John R. Wigham at a meeting of the Shipmasters Society held at the offices of the London Chamber of Commerce.

Building Trades Exhibition.—Prof. Henry Robinson is announced to lecture on "Electricity" at this exhibition, which will be opened at the Agricultural Hall, Islington, on Monday next.

Royal Meteorological Society.—At the meeting of this society on Wednesday evening, Mr. W. N. Shaw, F.R.S., delivered a lecture on "The Motion of Clouds Considered with Reference to Their Mode of Formation."

Heilmann Locomotives.—It is stated that the two Heilmann locomotives now being constructed for the Western Railway Company of France for express service between Paris and Dieppe, are to be ready next June.

Queenwood College.—We have received a card of the fixtures for the spring term at Queenwood College, near Stockbridge, Hants, controlled by the Queenwood Association for promoting the study of literature, science, and art.

City and Guilds of London Institute.—The institute's examinations in technology will be held on April 27, May 1, 4, 6, 8, and 9. All applications for examination in technology must be forwarded to the institute on or before April 1.

Institution of Electrical Engineers.—A paper by Mr. W. E. Langdon (member) "On the Employment of the Electric Light for Railway Purposes," will be read at the meeting of the institution to be held on Thursday next, the 28th inst.

Telephony between Holland and Belgium.—It is stated that an agreement has been signed between Holland and Belgium for the establishment of telephonic communication between the two countries. The first line between Brussels and the Hague will be opened on July 1.

Lighting of the Embankment.—In the London County Council (Money) Bill power is sought, among numerous other purposes, to light by electricity the Victoria-embankment, the embankment gardens, and Waterloo and Westminster Bridges, and to acquire tramways.

The Faraday Medal.—The Faraday medal of the Chemical Society has been conferred upon Lord Rayleigh in recognition of the investigation which has led to the discovery of argon. The previous recipients of the Faraday medal are Dumas, Canizzaro, Wurtz, Helmholtz, and Mendeleeff.

The Pacific Cable Question.—A telegram from Victoria (British Columbia) states that according to advices from Sydney, Mr. Larke, the Canadian agent, is of opinion that the laying of the Pacific cable is assured, provided that England assumes her share in the undertaking. Mr. Larke considers the prospect of business with Canada a good one.

New Editions.—Messrs. Whittaker and Co. announce the issue in a few days of a revised and enlarged edition of Poole's "Practical Telephone Handbook," and a third edition of "Electricity in our Homes and Workshops," by Sydney F. Walker, revised and brought up to date. A new addition of Allsops' "Practical Electric Light Fitting," has recently been issued by the same publishers.

"D. and S." Electric Lighting Accessories.—A February list of their accessories for electric lighting has been forwarded to us by Messrs. Dorman and Smith, of London, Manchester, and Glasgow. This particular list illustrates the "D. and S." porcelain switches, main switches, ceiling roses, cut-outs, wall sockets, lamp holders, brackets, and general fittings and main switchboards.

Electric Tramways in Paris.—A Paris correspondent states that the rejection of the metropolitan scheme by the Municipal Council has increased the problem of locomotion, which will have to be solved before 1900. So far the only proposals made are for the construction of new tram lines with an electric service within the precincts of the exhibition, and the building of new steamers for the Seine.

Leeds Tramways.—The Leeds Corporation intend to apply to Parliament, by way of petition for additional provision, for the insertion in a Bill now pending in the House of Lords of clauses to empower the Corporation to construct stations for generating electric power for the purpose of propelling carriages on the tramways, and to lay down dynamos, engines, and other apparatus for the working of tramways.

City and South London Railway.—The Bill, which seeks an extension of time until 1900 within which to enable the City and South London Railway to construct the authorised extension of their electric railway from Stockwell to Clapham, was on Wednesday referred to the Unopposed Bill Committee of the House of Commons, a settlement having been effected with the Lambeth Vestry, which was the only opponent.

Electricity in Mining.—In the annual report of inspectors of mines, Mr. Robson, of the South Wales district, states that the application of electricity to mining purposes continues to make steady progress, especially as a means of transmitting power. He has no reason to doubt that, with due care in the erection of plant and especially in the insulation of cables, electricity will afford a large measure of safety.

New Zealand.—The New Zealand Electrical Syndicate are receiving good support in Wellington, as is shown by the rapid increase in the number of installations. In October, 1893, only 700 lights were supplied to the public, whereas at the present time the number is about 8,000. The post and telegraph offices are being fitted throughout. It is anticipated that orders will shortly be received to instal the electric light in all the other Government offices.

Electric versus the Welsbach Light.—A correspondent informs us that a firm of Liverpool shipowners, who formerly had their offices lighted throughout with gas, burnt through Argand burners, desired to introduce some better means of illumination, but did not wish to have the electric light installed. The firm gave the Welsbach system

Digitized by Google

a trial, but after about two months' use they voted it as unsatisfactory, and at once gave orders for the electric light to be installed throughout.

Royal Society.—Among the papers down for presentation at yesterday's meeting were: by Lord Kelvin, P.R.S., and Messrs. M. McLean and A. Galt, "The Diselectrification of Air"; by Prof. V. B. Lewes, "The Cause of Luminosity in the Flames of Hydrocarbon Gases"; by Mr. E. C. C. Baly, "A Possible Explanation of the Two-fold Spectra of Oxygen and Nitrogen"; and by Messrs. A. W. Porter and D. K. Morris, "On the Question of Dielectric Hysteresis."

Northern Society of Electrical Engineers.—A smoking concert of this society will take place this (Friday) evening at the Palatine Hotel, Hunt's Bank, Manchester, commencing at 7·30 p.m. The following gentlemen were elected members at the meeting of the society held in Liverpool on the 11th inst.: Mr. E. W. Dickinson, Corporation Electricity Works, Bolton; Mr. D. C. Jolley, Corporation Electricity Works, Manchester; and Mr. W. H. Preece, F.R.S., C.B., Wimbledon.

Shot Firing in Mines.—Mr. Roskill's report on the Albion Colliery explosion will be published forthwith. An analysis of the case, signed by Mr. Robson, Mr. Hall, and Mr. Martin, inspectors of mines for the South Wales, the Liverpool, and the South-Western districts respectively, is appended to the report. In concluding their report, the latter take the opportunity to impress upon owners and managers of mines the urgent necessity that exists for dispensing with the use of explosives as far as possible, and to suggest that where explosives are used only the safest that can be obtained should be allowed. It is also recommended that all shots should be properly tamped with clay and fired by electricity.

Telephone Tax.—A strange restriction, the *Financial Times* states, of the privileges of members of the Stock Exchange has just occurred. For some time past they have had the free use of a telephone which connects the building with the offices of brokers, but within the last few days a new regulation has come into force, and now only subscribers of £5 have entry to the telephone-room. Apparently the only object of the rule is a tax, for if it were intended to prevent a broker from advising his clients, at their offices, as to changes in prices and the course of business, the imposition of a charge of £5 a year could hardly be expected to prove an effectual obstacle.

Cable Rates to South Africa.—A *Times* correspondent states that the negotiations, to which we referred in our last issue, between the Eastern Telegraph Company and the Cape, Natal, and Transvaal Governments and the Chartered Company for the reduction of the cable tariff have been concluded. Public messages will pay 5s. a word from April 1. The new agreement is to extend for 10 years after 1899, power being reserved to the Government to determine the agreement by 12 months' notice expiring five years after the begining of the extended term. The Cape will continue to pay the present subsidy of £15,000 a year until December, 1899, after which the subsidy will be £6,000 a year. The new rates are applicable to all countries in South Africa which are under British and Dutch jurisdiction.

Committee on Telephony.—As foreshadowed in our last issue, the following have been nominated as the Select Committee on telephone service: Captain Bagot, Mr. Baird, Mr. Benn, Sir C. Cameron, Mr. John Ellis, Sir J. Fergusson, Sir J. Goldsmid, Sir J. Gorst, Mr. Grant Lawson, the Solicitor-General, Mr. A. Morley, Mr. Moulton, Mr. Snape, Lord Stanley, and Mr. Tully. The committee have power to send for persons, papers, and records. The committee met on Tuesday and elected Mr. Arnold Morley as chairman. The committee will meet for the first time to-day (Friday) at 11.30 a.m., for the purpose of taking evidence, and afterwards on Tuesdays and Fridays. The first witness will be Mr. C. J. Lamb, the head of the Telegraph Department at the Post Office, and afterwards Mr. Provand, M.P., will be examined.

Royal Institution.—Among the lecture arrangements after Easter are the following: Prof. George Forbes, three lectures on "Alternating and Interrupted Electric Currents"; Prof. E. Ray Lankester, four lectures on "Thirty Years' Progress in Biological Science"; Prof. Dewar, four lectures on "The Liquefaction of Gases"; Dr. William Huggins, three lectures on "The Instruments and Methods of Spectroscopic Astronomy" (the Tyndall lectures). The Friday evening meetings will be resumed on April 26, when a discourse will be given by Dr. John Hopkinson on "The Effects of Electric Currents in Iron on its Magnetisation." Succeeding discourses will probably be given by the Earl of Rosse, Veterinary Captain Frederick Smith, the Hon. G. N. Curzon, M.P., Prof. Walter Raleigh, Mr. J. Viriamu Jones, Prof. Alfred Cornu, and other gentlemen.

Explosions in the Streets.—The Highways Committee of the London County Council were on Tuesday asked by Mr. Fletcher whether the committee had had under consideration the explosions which had taken place in the streets in connection with electric lighting. In reply, Mr. Edwin Jones stated that the Council had opposed the action of the Board of Trade in giving its sanction to the new transformer-chambers, and that the only course now open to them was to apply for an injunction to restrict the carrying out of such works. They had had five of these explosions during the last three or four months, two of them since the Board of Trade gave its decision in this matter, and he thought the responsibility for all future accidents that might take place would rest mainly with the Board of Trade. The Highways Committee can very well leave the matter in the hands of the Board of Trade.

Madras Tramways.—The Madras Electric Tramway, the *Indian Engineer* states, is an accomplished fact. Very successful trial trips have been made, and the first section is about to be, if it is not already, opened to traffic. This latest departure in the methods of traction employed in this country must needs be of interest to all, and the working of the tramway will be closely watched. There is really no tangible reason why electric traction should not succeed in India as well as it has in any other country; if it is only from a humanitarian point of view, it deserves to succeed in order to obviate the use of horses. It is but a sorry spectacle under the very best of circumstances, to see a heavily-ladened tramcar dragged through the intense heat of a Calcutta hot day, by a pair of unfortunate animals, though it must be admitted that every effort is made to render their task easy. Now that Madras has given the lead there should be no difficulty in other cities following.

City Electric Athletic Club.—This club, which was instituted in connection with the City of London Electric Lighting Company, Limited, will hold its third annual bohemian concert at the St. James's Hall (banqueting room), 73, Regent-street, W., on Tuesday next, the 26th inst., commencing at 7.45 p.m. The chairman will be Sir David L. Salomons, Bart., president of the club. The following will contribute to the programme: artistes—Miss Lily Seddon, Miss Florence Venning, Mr. Geo. S. Aspinall, Mr. Stuart Walker, and Mr. Alexander Tucker; musical

Digitized by Google

sketch, Mr. Walter Banks; recitations, Mr. Valentine Hill; humorous songs, Mr. Ambrose Thorne; ventriloquism up-to-date, Mr. Frederic Russell; cornet solos, Mr. L. Hawkins (H.A.C.); clarinet solos, Mr. James Hubert (late Coldstream Guards); accompanist, Mr. Tom Physick. There will be an orchestra of 30 performers. The Concert Committee are Messrs. H. Bacon, E. J. Frowein, and A. F. Harrison, 1 and 2, Great Winchester-street, E.C.

Telegraphic Cede Vocabulary.—The Postmaster-General, in reply to a question put in the House of Commons last week, stated that it was decided at the last International Telegraph Conference, held in Paris in 1890, that an official vocabulary should be compiled, and that the use of words taken from that vocabulary should be made obligatory for code telegrams in the European system at the expiration of three years from the date of issue of the book, but the employment of the vocabulary outside that system was left optional. The three years would expire on December 31, 1897. This country and its colonies being parties to the International Telegraph Convention, and the adoption of an official vocabulary having been decided upon by the union, it would not, he feared, be possible for him to accede to the suggestion that British merchants should be secured a continuance of the privilege hitherto enjoyed of using their own vocabularies, provided that they contained only words taken from the eight authorised languages.

Metric System of Weights and Measures.—The Select Committee of the House of Commons on weights and measures met again on Tuesday, when Mr. Alfred Spencer, chief officer of the Public Control Committee of the London County Council, was called. He stated that the Council were independent of the Board of Trade and appointed their own inspectors, who, however, had to pass a Board of Trade examination. As to the difficulties of a change of system, he mentioned that the County Council had made enquiries as to the probable cost of establishing new weights and measures in each of 11 of the leading trades. The average cost to the retail trader, using nine weights and 11 measures, would be £1. 8s. 6d., or about £80,000 for London. A reasonable period should be allowed before the new system came into use, and a further period before it was made compulsory. If school children were more thoroughly taught the metric system it would be a great assistance to any change. The Council was of opinion that the prohibition of the use of metric weights and measures for the foreign trade was unnecessary.

Telegraphic Communication under Difficulties. A contributor, writing to the *Indian Engineer* in regard to the Gilgit telegraph, says the winter in Kashmir has been an exceptionally severe one. A correspondent writing him from Srinagar on February 20, said it had been snowing steadily for 72 hours. The snow lay 3ft. deep in Srinagar, and at Baramula it was 6½ft. Before this snow-storm began, there was a regular hurricane for four days in the Gurais Valley, and the air was darkened with the whirling snow blown up. Notwithstanding this severe trial, the telegraph line to Gilgit continued to work without a breakdown, and the problem of keeping up reliable communication with that distant and important agency appears to have been successfully solved. The cold has been intense. Great floes of ice are floating down the Jhelum, which is very nearly frozen over. The Woolar Lake is completely frozen, and there has been skating on the Dâl, near the Nasim Bagh. How the telegraph staff isolated at Garais and Minimarg have been able to get on is a wonder; their experiences when the passes are open, and they are able to look once more upon the faces of their fellow men, should be interesting.

Electric Motors on War Vessels.—It is stated that the French claim to be the first to apply electricity to turret guns. A daily paper, however, states that in the matter of electric motors the English Admiralty have taken the lead. When the "Centurion" was fitted at Portsmouth it was intended, on the initiative of Sir Joseph Whitworth and Co., to apply an electric installation in the two barbettes, but as the plant and gear could not be supplied in time, and the vessel was wanted for China, the gunnery trials were prosecuted at Spithead about a year or so ago, under the ordinary conditions. Since then, however, in March last year, electric motors were experimentally applied to the 10in. guns in the turrets of the sister ship "Barfleur," and with such success that the battleship was enabled to make use of the innovation throughout the naval manœuvres. After returning to Chatham the same firm introduced some modifications in the installation with a view of simplifying the mechanism and giving the guns the full protection of the redoubt armour. The new arrangements were recently tested and proved thoroughly satisfactory, the fine sighting of the guns at all angles being under complete control.

Telephone Cables in Sewers.—It was mentioned at a recent meeting of the City Commission of Sewers that some doubt existed as to the right or legality of the Commission to accept payment from the City of London Electric Light Company in return for the latter being permitted to use the tubes already laid in the ground for the accommodation of telephone circuits. A somewhat similar case is reported from Paris, the dispute being between the State and the town of Paris. The second article of the Telegraph and Telephone Act of 1885 states that "telegraphic or telephonic wires other than those lines of general interest can only be placed in sewers belonging to communes after notice to the municipal councils and by paying a tax if required to do so by these councils." When the French Government took over the telephones in 1890, the town of Paris contended that it also transferred the liabilities of the company to the State, and a continuation of the payment of the taxes which the company paid until the transfer was made was demanded. The Minister of Commerce affirmed that the working of the Paris telephones by the State had terminated a commercial speculation and that the lines were of public interest. The matter was then taken by the town to the Conseil d'Etat who have now rejected the appeal of the town.

Wire Fence Telephones.—In a communication to the *Scientific American*, Mr. E. Aeggle, of Gunbower Station, Gunbower, Victoria, states that some two years ago he utilised the top wire of the existing fences on that station for telephonic purposes. Since his station was satisfactorily served by this inexpensive method (2s. 6d. per mile) of telephoning, he has received many letters asking particulars from all parts of Australia. At the present time there are many hundreds of miles of station fences throughout that and the neighbouring colonies brought into requisition for the purpose. The climate is very dry (average rainfall 8in. to 9in.) and in consequence insulation is not such an important matter. On that property at Gunbower there are about 600 posts to the mile of fencing, the wire passing through an augur pole in the ordinary way; the rust that forms on the wire makes a sufficiently thick skin to insulate it from slight moisture. At the straining posts the rust is filed off the wire at either side, and a piece of clean wire to carry the current round the post is tightly screwed on; at knots or loop joints a continuous connection in the same way is made. The ordinary long distance microphone transmitters are used at either end, with call-

Digitized by Google

bells and receivers. In addition, a portable instrument, which can be attached to the wire at any point when out on the run, is provided, and in this way messages can be sent to the homestead. The longest service is 16 miles, but one run has a continuous service of 28 miles, and from his experience there is no reason why in a dry climate it could not be utilised on much longer lengths.

Chemical Properties of Argon.—The *Times* states that M. Berthelot, the distinguished French chemist, and secretary of the Academy of Sciences, supplies the first bit of solid information concerning the chemical properties of argon. In experimenting with a small quantity of that substance furnished by Prof. Ramsay, he has found that under the influence of the silent electric discharge it combines with various organic compounds, and notably with benzene. It is decidedly interesting to discover that argon, which is supposed to be totally inert, and has been vainly subjected to all the most potent agencies at the command of the chemist, is all the time capable of forming a variety of combinations under conditions which always exist in the atmosphere. Great interest also attaches to M. Berthelot's communication in connection with the obscurity which hangs over the chemical nature and relationships of the new substance. For he pointed out years ago that nitrogen combines, under the influence of the silent discharge, with hydrocarbons like benzine, with carbohydrates such as go to build up the tissues of plants, and even with tertiary products such as ether. A bit of moist filter paper, for example, exposed to the silent discharge in presence of nitrogen, whether alone or mixed with oxygen, absorbs a considerable amount, producing a nitrogenised compound which, on heating with soda-lime, gives off abundance of ammonia. As argon seems to be absorbed in the same way, it would be very interesting to learn whether its compound also yields ammonia on heating, or if not ammonia, then what? M. Berthelot promises further details.

National Telephone Company. — The second annual dinner of the staff of the National Telephone Company took place on Friday evening at the Holborn Restaurant. In the absence, through illness, of Mr. James Staats Forbes, the chairman, the chair was taken by Mr. W. E. L. Gaine, the general manager. The company included Lord Kelvin, Lord Balfour of Burleigh, Sir Albert Rollit, M.P., Sir Robert Hunter, Mr. Dane Sinclair, Prof. D. E. Hughes, and Mr. W. A. Smith. After the loyal toasts the chairman sent a telephonic message to Mr. Forbes, who telephoned a reply. The chairman proposed "The National Telephone Company," commenting upon the progress which the telephone had made in a comparatively short period. In reply, Lord Balfour of Burleigh, vice-president, said that this was an age of experiments. The Post Office had recently completed a trunk communication between Scotland and the south as far as Birmingham. He hoped that before long it would be found possible to work a telephone commercially between London and the north. Lord Kelvin, responding for "Telephony," said that in 1876, when the telephone was first brought to this country, the general public looked upon it as a wild dream of the scientific imagination. Very soon it became a great working reality, and now, as they had heard, it had been extended to communication between Mid-England and Scotland. The toast in honour of the Post Office was coupled with the name of Sir Robert Hunter, who spoke of the cordial relations between that department and the company. That of "Our Guests," was replied to by Prof. Hughes, whose remarks are given in another column.

Polarisation.—In discussing this subject in the *Zeit. Physikal. Chem.*, Mr. J. Roszkowski states that he employed for the polarising E.M.F. a Gülcher thermopile of 50 elements capable of yielding a pressure up to 3·5 volts, a Leclanché cell and four standard Clark cells being employed for its determination. The cathode examined was immersed in an N/10 solution of sulphuric acid, and the polarisation determined by the measurement of the E.M.F. obtained from this cathode connected with a calomel element—that is, practically, the chain, cathode, N/10 sulphuric acid, potassium chloride solution, mercury. Experiments on the effect of the duration of the current were made with cathodes of polished and platinised platinum, polished silver and mercury, and the polarisation reached its maximum constant value in from two to three minutes (polished platinum 15 minutes). The effect of the current strength on the polarisation was obtained by the addition of external resistances. With a platinised platinum cathode of two square centimetres area and an E.M.F. of 3·3 volts, the polarisation decreased to a minimum of – 180 volts when 700 ohms had been added, further addition having no effect. A similar decrease was obtained by the addition of internal resistance—that is, substitution of Leclanché cells for the thermopile. The influence of the size of the cathode was investigated by the use of mercury electrodes of respectively one and two square centimetres, and although for low E.M.F.'s the smaller cathode gave markedly greater polarisation, at 3·3 volts the values were almost identical. The nature of the surface was then altered and platinum electrodes (1) polished, (2) platinised, (3) platinised and heated to redness, (4) covered with scratches, were employed. Very different values for the polarisation were obtained, the highest values being obtained with (4) and lowest with (2). The platinised cathode also gave the curve of polarisation, polarising E.M.F., approximately a straight line of inclination $\tan^{-1}\frac{1}{3}$. In no case does a maximum value occur, and the differences the author considers to be due to different occluding powers of the surfaces. Similar experiments were performed with silver cathodes with entirely similar results, the differences between the differently prepared silver cathodes being, however, not as great as with the platinum electrodes.

Economy in Coal Consumption.—The National Electric Light Association Committee on Data presented a tabulated statement at the meeting recently held at Cleveland. The table contained reports from 24 stations using coal as fuel. The highest economy is shown in one case where 262 watts are generated from 1lb. of coal, the plant furnishing nearly 23,000,000 watts during 24 hours, the equipment being triple-expansion engines with dynamo on the engine shaft, and horizontal water-tube boilers with heaters, without economisers, the firing being done by hand. This result is secured from one-half each soft coal and hard screenings. An examination of this report proves it to be a high average for 24 hours, as with an evaporation of 9·37lb. of water per pound of combustible, and a water consumption of 17lb. per horse-power, allowing 10 per cent. non-combustible in the coal, and taking the efficiency of the generators as stated at 85 per cent., we have $\frac{9\cdot37\times\cdot90}{17}\times746\times\cdot85=314$ watts produced from 1lb. of coal. This average is much nearer the theoretical efficiency of a modern steam plant than any report previously received by this committee. Taking an average of the 10 reports from stations generating over 5,000,000 watts in 24 hours, we have 147·5 watts per pound of coal, or a production of 1 e.h.p. for 4lb. of coal on a basis of the efficiency of the generating machinery as stated in the last report by this committee. Previous reports by this committee have been criticised as inaccurate and incomplete, and an attempt has been made

Digitized by Google

in the statement submitted to improve it in both these particulars. From the first the results of this work have been handicapped by reports from the central stations incorrect, incomplete, and based upon a variety of testing instruments constructed without any absolutely uniform standard. And, again, many central-station managers do not wish to have their work made public, and in order to get at the results secured by these people, the information has previously been furnished to the committee, through the secretary, in such a manner that the committee were relieved of the responsibility of the exact source of the information furnished. This in a measure defeats the main object of the work. A careful review of this work for the past three years reassures this committee that the present method of securing data from central stations by individual effort on the part of the committeemen, with the understanding that the information is to be held confidential, meets all the requirements, as any manager can communicate with the author of any report either through the committee or the secretary of this association.

Traction in New Zealand.—It is now some time since we referred to the proposal of the Dunedin City and Suburban Tramways Company, to substitute electric for horse traction. The report of the directors which, according to the *New Zealand Journal of Insurance*, was adopted at a meeting of the company held in January stated that "The protracted negotiations which have been proceeding with the view of introducing electricity as a motive power, have resulted in the Government agreeing to bear the cost of the necessary alterations to the telephone system, and during the last session of Parliament a Tramways Bill was passed enabling the Government to grant powers to tramway companies to use electricity. The directors hope shortly to obtain the Orders-in-Council, the details of which are now in course of being settled. The haulage contract expired in December last, and seeing the difficulties in the way of the proposed change of haulage, the directors deemed it advisable to enter into a new contract for a term of three years. The company have, however, the option of terminating the contract at an earlier date." In regard to this Mr. G. Fenwick (the chairman of the company) stated at the meeting in question that it was two years and eight months since the first offer was made to the company to change the system, and that it was over two years since the agreement was actually entered into with the Dunedin syndicate, who took up the matter energetically and carried on negotiations almost to a successful point. But they were blocked by the fact that the law of the colony at the time did not give power for the use of electric traction. The directors set themselves to work to get over that difficulty, and it seemed a strange thing, but it was nevertheless true, that they had been driven to all sorts of means, including personal interviews with Ministers of the Crown, evidence before a Parliamentary Committee, and endless correspondence by letter and telegram, to accomplish this end, and it was only on October 23rd last that they succeeded in getting the necessary Bill through the Legislature. The Bill was passed in the very last week of the Session. But they still required an Order-in-Council before the company could give a clear title to a purchaser. He was glad, however, to be able to say that the details of the Order-in-Council were now practically settled. He could not definitely promise that this would be concluded by a certain day, but virtually the thing was settled. Meantime, as to the arrangements which had been entered into by the syndicate with the capitalists they were dealing with at Home, they did not look too promising. They might possibly fall through. He could not say whether this would be so or not. Capitalists in England did not care to keep their money locked up for nearly three years, and doubts had arisen as to whether all these negotiations would not have to be started afresh. He could not say for certain. The shareholders, however, might rest satisfied that the directors would do their best to bring about this long desired change in the haulage arrangements.

Storage of Energy in Central Stations.—A very lengthy paper on "The Storage of Energy Essential to Economy of Working in Central Stations" was presented by Mr. N. W. Perry at the recent meeting at Cleveland of the National Electric Light Association. The author stated that when we consider how enormously short the results of actual practice in lighting stations are of those which are obtainable under the most favourable conditions with the same machinery, it behoves us to enquire into the cause of this deficiency and to see how far we can remedy it. Prof. Kennedy had made some very careful tests to indicate the effect of variable load upon coal consumption. Dividing the day into three portions, he determined the fuel consumption, the feed water evaporated, and the indicated and electric horse-power developed during each period in an English lighting station. During the periods of light load the fuel consumption per horse-power is very large. Captain Sankey had applied Mr. Willans's formula to find the steam consumption of one or more engines working against a variable load in an electric lighting station. He takes a normal midwinter load curve and examines how the necessary current could be supplied during the 24 hours (1) with an engine capable of exerting the maximum power required, (2) with smaller engines. The results, rearranged and a little modified, are given by Prof. Unwin, it being assumed for convenience that the maximum load is 500 e.h.p. and that the engines are non-condensing. These results closely agreed with Prof. Kennedy's figures, derived from direct tests which gave 24 per cent. increased consumption at mean load over that at maximum load. Having shown by Prof. Unwin's figures that with engines working on a very regular load the total annual cost per electrical horse-power is less than half of that with engines running with a variable load under conditions similar to those of a central station, the author discussed the annual cost per horse-power with various systems of storage. The following table gives the results obtained by the author. The table shows the cost to produce for one year 1 e.h.p., with coal at \$1·75 per ton and at \$3·50 per ton; also, the saving effected by the various methods over present methods in a station having a mean load 25 per cent. of its maximum:

	Annual cost of 1 e.h.p. Coal \$1·75 per ton.	Annual cost of 1 e.h.p. Coal \$3·50.	Saving effected. Coal \$1·75.	Saving effected. Coal \$3·50.
Present method, steady load	\$48·68	\$65·62	—	—
,, gas-engine	88·28	103·61	\$29·50	\$44·79
Combined feed and steam storage	94·42	111·35	23·36	37·05
Feed storage	97·58	117·58	20·20	30·82
Without storage, load factor 25%	117·78	148·40	—	—
Steam storage	117·84	134·77	− 00·06	+ 13·63
Complete battery storage	123·13	145·74	− 5·35	+ 2·66

The author concludes that of all the methods of storage available the storage battery would, on theoretical grounds, be the best, because of its forming the last link in the chain, thereby giving the economies of continuous working to all that precede. Unfortunately, it involved such large losses in itself as to nearly, if not quite, nullify the advantages it would otherwise present. And, again, its extreme cost above all other methods renders it unavailable in any complete storage project, unless fuel is dear. We are therefore compelled, he states, to go back of the engine for our equalisation schemes and put up with the losses due to variable load upon all that follows.

THE EARLY HISTORY OF TELEPHONY.

We reproduce below the text of the reply of Prof. D. E. Hughes, F.R.S., to the toast of "Our Guests" at the banquet given by the staff of the National Telephone Company on the 15th inst.:

I am exceedingly grateful to you for having so kindly mentioned my name in connection with the toast of your guests, and I am sure that I am only expressing the sentiments of all your guests in thanking you for having so kindly invited us to participate in this magnificent banquet on such an important occasion.

To me this is indeed an important event in the history of telephony, for I see around me some 200 members of the staff of the National Telephone Company, which now represents one of the most useful and powerful commercial organisations of the present age. When I look back only some 40 years to the first printed idea in France, and some 30 years to the birth in Germany of its first telephone, and that it is only 18 years since the idea became really practicable, I am indeed astonished at its wide-spread success, so that what was a few years since a scientific toy, now has become a necessity of our present age.

The earliest record of a perfect theoretical electric telephone was contained in Du Moncel's "Exposée des Applications," Paris, 1854; when M. Charles Bourseul, a French telegraphist, conceived a plan of conveying sounds and speech by electricity. Suppose, he explained, "that a man speaks near a movable disc sufficiently flexible to lose none of the vibrations of the voice, that this disc alternately makes and breaks the current from a battery; you may have at a distance another disc which will simultaneously execute the same vibrations." Unfortunately M. Bourseul did not work out his idea to a practical end, but in these few words we have the shortest possible explanation of the theory of our present telephones.

It is now exactly 30 years since my first experiments with a working telephone, for in 1865, being at St. Petersburg in order to fulfil my contract with the Russian Government for the establishment of my printing telegraph instrument upon all their important lines, I was invited by his Majesty the Emperor Alexandre II., to give a lecture before his Majesty, the Empress, and Court at Czarskoi Zelo, which I did, but as I wished to present to his Majesty not only my own telegraph instrument, but all the latest novelties, Prof. Philipp Reis, of Friedericksdorf, Frankfort-on-Maine, sent to Russia his new telephone, with which I was enabled to transmit and receive perfectly all musical sounds, and also a few spoken words, though these were rather uncertain, for at moments a word could be clearly heard, and then from some unexplained cause no words were possible. This wonderful instrument was based upon the true theory of telephony, and it contained all the necessary organs to make it a practicable success. Its unfortunate inventor died in 1874, almost unknown, poor, and neglected, but the German Government have since tried to make reparation by acknowledging his claims as the first inventor and erecting a monument to his memory in the cemetery at Friedericksdorf.*

The duties connected with my printing telegraph instrument prevented me from continuing my experiments with the telephone of Prof. Reis; but in 1876 we heard in Europe of the invention by Prof. Alexander Graham Bell of his wonderful telephone, by means of which the practical transmission and reception of human speech had become an accomplished fact, and early in 1877 the instrument was brought to England. I at once resumed my experiments of 1865 with it, and found that Prof. Bell's telephone, considered as a receiver, was absolute perfection, but that his mode of transmission of magneto-electric currents, generated solely by the movement of an iron diaphragm near its electromagnet, was defective, as the currents produced were too feeble for any practical use. I then tried to adopt Prof. Reis's system of using a separate battery, brought into play by the movement of a diaphragm.

I will not cite the numerous experiments and difficulties that I met with in this research; but at last I succeeded in finding the effect I wished, by the use of a very slight electric contact of the surface of solid carbon, or any other metals, such as ordinary iron nails. This slight or microphonic contact has the remarkable power of varying the resistance, and, consequently, the force of an electric current, exactly in accordance with the sonorous vibrations of the human voice; and, in fact, the contacts could easily be rendered so sensitive that the instrument became a true microphone, rendering audible sounds far too feeble for the human ear. All of these results I gave freely to the public, and brought before the notice of the scientific world in a paper I read to the Royal Society in May, 1878.

Another discovery which I made in the continuance of my researches, which is now of the highest utility to far-distant telephony, was the use of twisted wires, or wires so arranged upon their insulators that the whole line should gradually revolve on its axis, so as to prevent induction from other independent wires. This was given freely to the world in my paper read before the Society of Telegraph Engineers, March 12, 1879, and fully illustrated by engravings in *Engineering* of the same week. In order to understand this, I will quote a single paragraph from this paper.

"If two ordinary aërial lines are thus used, they should have the twist given to these wires by changing their position relatively to other wires from vertical to horizontal at each pole or mile. Thus, if we had two lines, A and B, they should have their four relative positions repeated as often as possible—viz., A B, then $\frac{B}{A}$; then B A and $\frac{A}{B}$."

This is the system employed by the telephone line between London and Paris, and, in fact, upon all successful long-distance telephone lines throughout the world, so I think it is only fair that it should be known that I discovered and published this long before long-distance telephony was ever brought into use.

During the same months of 1877 that I was experimenting with Prof. Bell's telephone, Mr. Edison in the United States was also engaged upon a similar research—viz., endeavouring to adopt Prof. Reis's method of transmission by a diaphragm and separate battery, and he succeeded in inventing and patenting his form of transmitter, which he called the carbon telephone. This transmitter was brought to England in 1878, and it worked remarkably well, although I felt convinced then, as I am still, that the theory upon which it was supposed to work was wrong. Mr. Edison's views were that its mode of action was based upon the varying resistance obtained through a varying pressure of the diaphragm upon an elastic button of carbon. (He believed that the varying resistance of carbon by pressure was an original discovery, but it was well known for many years previous in Europe through its publication by Du Moncel, and its application by Clerac in his carbon resistance tube, whose resistance was varied according to the pressure given to its adjusting screw.) The error of this theory is shown by the fact that we cannot obtain more than a difference of resistance through pressure upon any conducting substance but of a few ohms, say one to ten, but with a microphonic joint we can easily obtain the widest possible range, from almost zero to an infinity of resistance, and this with the smallest possible expenditure of mechanical energy from the diaphragm, or even without a diaphragm. I believed then, as I do still, that its excellent functions were due to a microphonic joint, of which, and of the value of which, he was unaware, and I also believe that the often successful transmission of words by Prof. Reis's transmitter was due to an accidental adjustment of his contacts to a true microphonic condition. He was, of course, unaware of the power and importance of microphonic joints, else his telephone would have been a practical success at once.

Unfortunately, Mr. Edison and myself had a painful discussion as to priority of invention, in which we have both sustained our individual views up to the present time. Mr. Edison's views have been sustained by all the companies owning his patent; mine have been sustained by nearly the whole scientific world. The companies, however, whose interest it was to sustain and possess for themselves an

* "Philipp Reis, Inventor of the Telephone." A biographical sketch by Prof. Sylvanus P. Thompson, F.R.S., etc., London. E. and F. Spon, 1883.

Digitized by Google

entire monopoly, have spared neither wealth nor power to obtain this coveted monopoly, and by the means of the ablest legal counsel and expert witnesses they obtained a legal decision giving them the sole right to the use of a diaphragm pressing upon a variable resistance, notwithstanding that the diaphragm was the discovery of Prof. Reis and microphonic contact by myself.

This is all now past history, but I am now more than consoled by the fact that at the present time there is not a single transmitter in practical use throughout the world whose function is not based entirely upon its microphonic joints, whether in the form of solid conductors pressing upon each other, or when these contacts are multiplied as in the form of granules or powder.

In conclusion, it gives me great pleasure to call attention to the vast progress and improvement in the telephonic system, due to the energy and enterprise of the different telephone companies. The telephone and microphone would have never reached its present vast stage of usefulness if it had not been for the establishment of the exchange system, with its complex and costly system of switchboards. This has enabled a single subscriber upon any separate line to be brought into almost instantaneous connection with any chosen subscriber out of thousands on the list. They have built the best possible of lines, and whenever possible have given a complete metallic circuit in order to avoid induction from other lines.

I beg to thank you for having so kindly listened to my few remarks, and to thank you most sincerely, in the name of your guests and myself, for the warm hospitality with which you have welcomed us here this evening.

ELECTRIC CURRENTS OF HIGH PRESSURE AND PERIODICITY.*

BY A. A. C. SWINTON.

The experimental effects that I propose to show this afternoon are all produced by utilising the disruptive discharges of Leyden jars to give electrical impulses of comparatively considerable magnitude as regards energy, but of exceedingly short duration as regards time.

As is well known, if a Leyden jar be discharged through a stout copper wire forming a circuit of small resistance, a surging of the electrical charge is set up, with the result that the electric current which passes through the wire is of the nature of a gradually dying-away oscillation. The action may, indeed, be compared to what occurs when a pendulum, immersed in some viscous fluid, is suddenly released from an inclined position and swings backwards and forwards with a gradually decreasing amplitude of oscillation until it comes to rest; or we may make the analogy more exact by comparing the effect to a loaded spring bent aside in a resisting medium and then let go. The pliability of the spring corresponds to the capacity of the condenser, its displacement to the electrical charge, the load or inertia to the self-induction of the circuit, and the viscosity of the fluid to the resistance of the circuit.

Thus the total duration of the discharge of a Leyden jar varies with its electrostatic capacity, being longer for large jars than for small. At the same time, both the duration of the discharge and the rate of oscillation are dependent upon the resistance and self-induction of the discharging circuit. In apparatus of the kind that we employ the conditions are exceedingly complex, and consequently calculations as to the duration of the discharge, or as to its rate of oscillation, must necessarily be only approximate. The total duration of the discharge itself can, however, be fairly accurately measured experimentally by means of a revolving mirror, and I think you may take it as tolerably correct when I tell you that the total duration of each discharge of the batteries of Leyden jars that we have here, and are going to use, is about $\frac{1}{50000}$ of a second. It has been further calculated that, with the conditions that we are working under, the rate of oscillation should be about 200,000 complete periods per second, so that apparently we get about four complete oscillations in each of our discharges.

* Contribution to the Professional *Papers* of the Corps of Royal Engineers, Chatham.

Our jars are charged by means of an alternate-current dynamo machine, which has a frequency of approximately 100 complete alternations per second. The jars are charged and discharged at each half-period, consequently one in each $\frac{1}{200}$ of a second. The duration of the discharge is, as already mentioned, $\frac{1}{50000}$ of a second, and consequently, if we devote our attention merely to what is taking place in the discharging circuit, there are intervals between each discharge of $\frac{249}{50000}$ of a second, during which intervals there is no current passing at all.

Fig. 1 shows this from a diagrammatic point of view. Only four discharges are shown, and it has unfortunately not been possible to show the intervals between them to scale, as, if shown on the same scale as the discharges, each of which on the diagram occupies 10in., the intervals ought to be no less than 208ft.

It has been usual to call oscillatory currents produced in this manner "high frequency" or "high periodicity electric currents." I am not sure with whom the term originated, but I think it was with Mr. Tesla, to whose investigations in this particular branch of electrical science we all owe so much. I am bound to say, however, that the term seems to me to be a very unfortunate one, as, though the periodicity is decidedly high during each discharge, the discharges are of so very short duration, and are spaced by such comparatively long intervals, that the average frequency is really not high at all; in fact, in the experiments I am about to show you, the average frequency appears only to be about 800 a second as against 100 a second, the periodicity of the alternator supplying the original current.

Further—and what I am now going to say is, I believe, in direct contradiction to the orthodox view—it does not appear to me that any high frequency at all is necessary

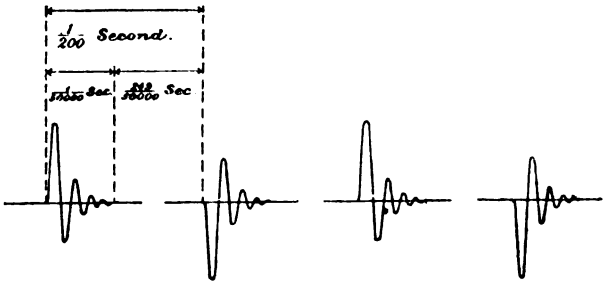

FIG. 1.

to explain the effects produced. All that is necessary is that the electric current should be delivered in impulses of exceedingly short duration, in which the current and voltage rise from zero to enormously high maxima, and fall again to zero with exceeding suddenness. The defects are, in fact, due to the rapid rate of change.

Now, oscillatory or pulsatory currents of the description that I have mentioned behave in many respects in quite a different manner from continuous or ordinary alternating currents. This is due to the fact that while with ordinary alternating currents the effects of impedence, induction, and electrostatic capacity are comparatively small, unless we take special means to render them operative, with our oscillatory currents these effects are comparatively enormous, and show themselves whether we will or no.

To take first of all the case of impedence. We have here a thick copper wire bent into a U-shape, which would conduct an ordinary alternating current with practically no impedence at all. We have it connected, as shown in Fig. 2. We start with a 100-volt alternating current of the ordinary description, which passes through the primary of an induction coil. From the secondary of this coil we obtain some 20,000 to 30,000 volts, This high pressure current charges the Leyden jars at each half-period up to a point where the air resistance across the spark gap is broken down, and a disruptive oscillatory discharge takes place. In this manner we obtain an oscillatory discharge of electricity through our U-shaped piece of copper wire. In order to let you see the effect of the impedence, I will connect these incandescent lamps across from one leg to the other of the U-shaped wire. You will observe that though short-circuited by the wire, which has enormously less ohmic resistance than the lamp filaments, the latter

Digitized by Google

incandesce brightly. The oscillatory current, in fact, does not take the path of least ohmic resistance, as might be expected, but the shortest path—*i.e.*, that of least self-induction and impedence. By sliding the lamps up and down we can make them burn more or less brightly, and by choosing suitable positions we can make lamps varying in voltage from 20 to 100 volts all burn with uniform brightness.

Again, oscillatory electric currents such as those with which we are dealing, have much more powerful inductive effects than ordinary alternating currents.

We have here two circles, each consisting of a single convolution of thick copper wire. One of these circles has a 20-volt 5-c.p. incandescent lamp connected to the two ends of the wire, and the other circle is connected as was the U-shaped wire in the last experiment, so that we can send oscillatory discharges through it. We will hold the two circles facing one another about 6ft. apart and turn on the current. As you see, the lamp filament is gradually becoming red hot, showing that the oscillatory current passing through the one circle is inducing an electric current in the other. If we bring the circles nearer together the light becomes brighter, and with an interval of 2ft. the lamp is fully incandesced.

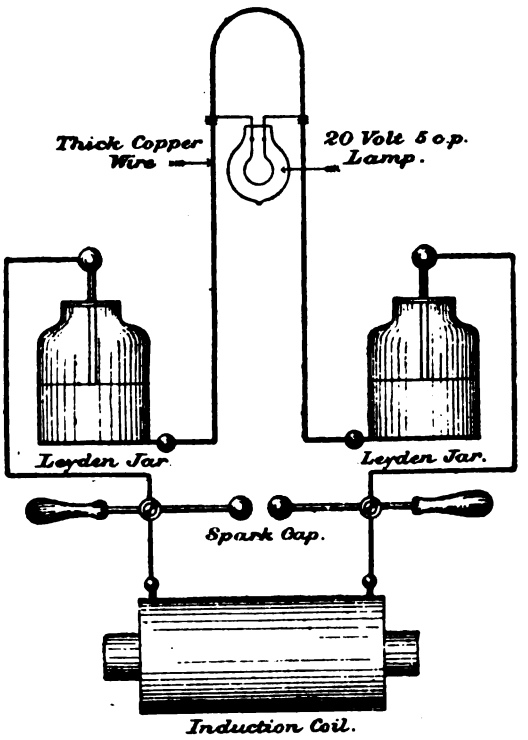

FIG. 2.

One of the most striking facts in connection with these oscillatory currents is the small physiological effect that they appear to have on the human frame. As is well known, the discharge of a good-sized Leyden jar, if taken direct, occasions a most violent shock to the system, and may, indeed, be sufficient to destroy consciousness for a time, or even to cause death. The current from a medical magneto machine, or even a small induction coil, is sufficiently unpleasant for most people, while that from an alternate current dynamo giving 1,000 to 2,000 volts is used for official electrocution in the United States of America, and has been the cause of more than one death in this country. The electric currents employed in medicine rarely exceed a few thousandths of an ampere, muscular fixation and other unpleasant results being usually produced when more than 10 to 20 milliamperes of continuous, or two to six milliamperes of alternating or interrupted, current is passed through the body.

We have here an ordinary 5-c.p. 100-volt lamp, which, with continuous or ordinary alternating current, requires about one-fifth of an ampere or 200 milliamperes to bring it to full incandescence. This is, of course, a much greater strength of ordinary current than anyone could bear for a moment. We will incandesce this lamp with current conveyed through the bodies of two persons. The connections are as shown in Fig. 3, and, as you will observe, there is no connection between the lamp and the other apparatus except through the arms and bodies of the two operators. As you will see, the lamp filament is brought up to full incandescence when we turn on the current.

Various theories have been propounded to account for the harmlessness of these currents. Some have supposed that the human body acts not as a conductor, but like a condenser with regard to the passage of alternate currents, forgetting that were this the case the impedence offered to oscillatory currents would be very small, and the application of high voltages, such as I have been using, would consequently be serious. Some, on the other hand, have imagined that it is all a question of the nerves, which they assume to be, as it were, tuned only to respond to alternations of comparatively low periodicity, and being unaffected by those above a certain range, as is the eye to luminous waves above the frequency of violet light.

The real facts of the case seem to be that wherever these oscillatory currents are harmless, it is simply for the reason that the quantity of electricity they transmit in any given time is too small to do any injury. Leaving on one side

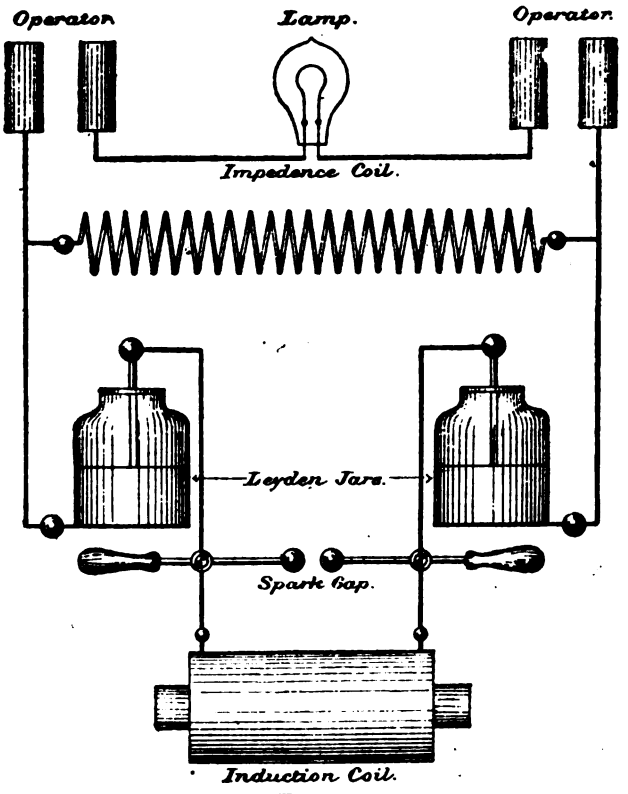

FIG. 3.

those physiological effects which from the burning and disruptive action produced in the tissues traversed are clearly due to the internal production of considerable quantities of heat, the physiological effects of electric currents seem most probably to be due to chemical decomposition—in fact, to electrolysis. Now the amount of electrolytic effect in any given time, is of course, proportional to the quantity of electricity—that is to say, to the number of the coulombs passed in that time. What, therefore, can be more natural than that the physiological effects of electric currents should, within limits, be proportional to the coulombs of electricity passed.

It will, however, be said that in the lamp experiment I have just shown you the current in the lamp must have been one-fifth of an ampere, and that, consequently, whatever the description of the electric current—continuous, alternating, or oscillatory—one-fifth of a coulomb was passed through the arms and bodies of the operators during each second that the lamp was lighted.

A little consideration will, however, show that this is by no means the case. In the first place, as has been shown by Lord Kelvin, oscillatory currents which rise and fall between minimum and maximum very rapidly do not flow uniformly through the section of a conductor. They tend to keep on the surface, and given sufficiently sudden

Digitized by Google

fluctuations, may only be, as it were, skin deep. Applying this to the filament of our lamp the effect is to increase its resistance, since only a part of the section of the filament acts as a conductor. The filament might, in fact, be a hollow tube instead of a solid wire. We have ample sufficiency of available voltage, and though the strength of the current may be small, the resistance being high there is a sufficient expenditure of watts to raise the filament to incandescence. The lamp, in fact, ceases to be a 100-volt lamp taking one-fifth of an ampere, and becomes, may be, a 1,000-volt or even a 10,000-volt lamp, taking only a tenth or a hundredth of that amount of current.

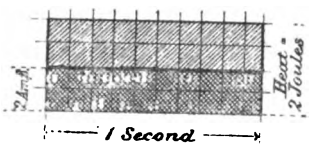

FIG. 4.

Steady Current.—Assumed resistance = 1 ohm; assumed quantity, 2 coulombs; time = 1 second; ∴ current = 2 amperes; ∴ heat generated = 2 joules.

There is also another point to be borne in mind. The current is delivered in impulses of exceedingly short duration. If we turn to Fig. 4, the double-cross shaded portion of the figure represents a current of two amperes flowing for one second of time. The area of this portion thus represents two coulombs of electricity. If we assume that this current is being passed through a resistance of one ohm, the heat generated in the resistance will clearly be equal to two joules. So much for continuous current. If we now turn to Fig. 5, we have a similar quantity of electricity—namely, two coulombs—passed through a similar resistance of one ohm; but instead of sending the current through continuously for one second, we will suppose it to be sent through in four pulsations, each lasting for one-tenth of a

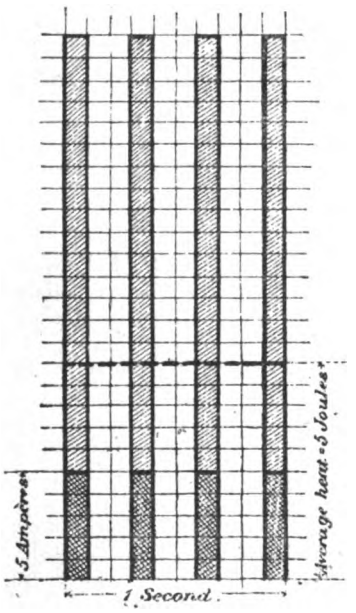

FIG. 5.

Pulsating Current.—Assumed resistance = 1 ohm; assumed quantity = 2 coulombs; total time = 1 second; duration of each pulsation, one-tenth second; then average current during each pulsation = 5 amps, and heat generated = 5 joules.

second, with intervening spaces of one-fifth of a second of no current at all. In order to pass our two coulombs within the second under these conditions, the average current during each pulsation will have to flow at the rate of five amperes, and the amount of heat generated, being proportionate to the square of the current, will be one and a quarter joules for each pulsation. The total heat generated during the second will, therefore, be equal to five joules, as against the two joules generated when we employed a steady current. Conversely, of course, the same quantity of heat can be generated in a given resistance and in any given time with a pulsating current with a less quantity of electricity than will generate this quantity of heat in the same time with a steady current. Further, the shorter the duration of the impulses the smaller is the quantity of electricity necessary, so that when we come to impulses of such exceedingly short duration as $\frac{1}{50000}$ of a second, such as we have been using in our experiments, the quantity of electricity necessary to produce the amount of heat required to incandesce our 5-c.p. lamp must be exceedingly small indeed.

So far we have been dealing with what I may term "primary oscillatory currents"—namely, currents that are derived directly from the Leyden jars without transformation. We will now try the effect of a step-up transformer which is contained in this box, and is entirely immersed in resin oil, in order to prevent sparking and the dissipation of energy by leakage either in the shape of conduction or brush discharges. The arrangement of the connections may be as shown in Fig. 6.

We are now dealing with oscillatory discharges having a potential difference that may be measured in hundreds of thousands of volts, and, as you will notice when the light is put out, the brush discharge effects are very striking. If I present my hand to one of the terminals of the coil sparks shoot out to my fingers. These sparks cause a painful pricking, but if I take a piece of metal in my hand and present it to the terminal I can take a violent discharge of sparks practically without any sensation. If I take hold of one terminal of the coil with one hand, which I can do without hurt, and present the other hand to the outside of the box of oil containing the coil, streams of sparks issue from my finger tips. Again, having hold of one terminal I can draw sparks from any body having electrostatic capacity, such as another person or any metallic body, merely by bringing my free hand, or for that matter my foot or any part of my body, near to them.

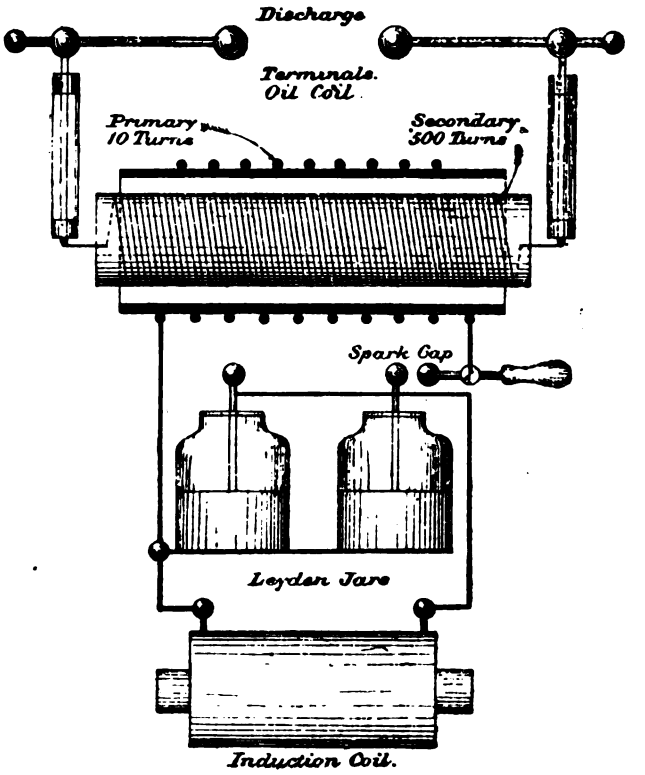

FIG. 6.

The high-tension oscillations have also marked electrostatic inductive effects. We will show this by attaching a tin-plate to each of the two terminals of the coil. We have here two other tin-plates, between which an incandescent lamp is connected. When we bring these latter plates within a foot or 6in. of the others, the lamp incandesces brightly. We can also incandesce a lamp filament by connecting one lamp terminal to one coil terminal and merely touching the other lamp terminal with a piece of metal held in the hand. The operator can stand upon an insulated stool, it makes no difference, as the effect is due not to any circuit being established, but to the electrostatic capacity of the operator's body. The electricity in fact merely runs in and out of the operator through the lamp, and thereby incandesces the latter.

Digitized by Google

Pretty effects can be shown by passing the high-tension discharge through a piece of wood, the sparks finding their way through the substance of the material and lighting it up with a dark red colour. Or a piece of glass, one side of which is covered with tinfoil, may be placed between points connected to the terminals of the coil. As will be seen, the discharge spreads out in fiery streamers over the glass with a loud roar. By substituting a dry photographic plate for the glass we can obtain photographs of the discharge taken with its own light. I have had lantern slides made of photographs produced in this manner, and, as you will see, they give very beautiful effects. The figures produced by positive electricity are irregular, somewhat resembling the rivers on maps. Those produced by negative electricity are, on the other hand, beautifully curved, and are like feathers or palm branches. Oscillatory discharges show both positive and negative figures combined.

The oscillatory electrostatic stresses set up in the neighbourhood of the coil will also produce luminosity in vacuum tubes. If I wave the tubes rapidly you will notice the discontinuity of the light, which is due to the intervals of time between the succeeding groups of oscillations. I have here a cylindrical vacuum tube, outside of which is wound a few turns of thin wire in the form of an open spiral. I connect one end of this wire to one terminal of the coil, and you see two luminous spirals twisting in and out of each other. One is the wire, which glows with a dark purple colour; the other is a species of ghost produced by molecular bombardment inside the tube.

The luminosity of wires can, however, be shown on a larger scale. We have here two circles of wire, a large and a small one. We will connect them respectively to the two terminals of the coil, and place them concentrically in one plane. When we switch on the current and lower the gas you will see that both wires glow brightly, while the interval between them is filled with streamers of purple light; or we can connect these two parallel wires which reach to the other end of the lecture hall, and which become luminous throughout their entire length.

These are all the experiments I have to show to you this afternoon. These phenomena may not in themselves have any immediate useful application, but they are in many ways very instructive. In addition, the essence of science is the correlation of facts, and the further we pry into the secrets of nature the more we are likely to achieve useful results.

PRACTICAL NOTES ON DYNAMO CALCULATION.*

BY ALFRED E. WIENER.

(Continued from page 283).

(43) *Magnet Cores.*—(*a*) *Material.*—The field cores should preferably be of wrought iron, or of cast steel, in order to economise in magnet wire; for the use of cast iron, on account of its low permeability, would require cores of at least $1\frac{2}{3}$—*i.e.*, almost twice—the cross-section, and therefore a much greater length of wire to obtain the necessary magnetising force. With the smaller wrought-iron cores the leakage would also be less.

In spite of this decided advantage of wrought-iron cores, cast-iron field magnets are very common, since the temptation to use castings instead of forgings is very great. Where weight and bulk are of no consequence, a cast-iron field magnet may prove nearly as economical as one of wrought iron costing considerably more, but the former requires from one-third to one-half times more wire to encircle it than a wrought-iron one of similar magnetic density, in case of circular cross-section, and it is evident that this, by intro ducing additional electrical resistance, will prove a constant source of unnecessary running expense.

As to the use of steel in dynamos, H. F. Parshall, in a paper delivered before the Franklin Institute, states that magnet frames made of cast steel are 25 per cent. cheaper than those of cast iron, but possess the disadvantage of being not as uniform in magnetic qualities as cast iron. He further asserts that good cast steel should not have greater percentages of impurities than ·25 per cent. of carbon, ·6 per cent. of manganese, ·2 per cent. of silicon, ·08 per cent. of phosphorus, and ·05 per cent. of sulphur. The effect of carbon is to lessen the magnetic continuity and to greatly reduce the permeability; carbon, therefore, is the most objectionable impurity, and if possible, should be restricted to smaller amounts than the maximum above quoted. Manganese, in quantities larger than stated, seriously reduces the magnetic susceptibility of the steel, a 12 per cent. mixture having scarcely greater susceptibility than air. Silicon is objectionable through facilitating the formation of blowholes, and from its hardening effect.

E. Schulz, in comparing two dynamos differing only in the material of the field frame and in the magnet winding, finds that the weight of a cast-steel magnet frame is about one-half of that of cast iron, and that the weight of the copper for the magnets, on account of the smaller cross-section and the greater permeability of the cast steel, is reduced to somewhat less than one-half. The price of the frame will accordingly be about $1\frac{1}{4}$ times that of the cast-iron one, but on account of the reduction of the copper weight, the cost of the whole machine will be less for a cast-steel than for a cast-iron frame, the total weight being less than one-half in the former case.

According to Prof. Ewing, the permeability of good cast steel at low magnetic forces is less than that of wrought iron, but the reverse is the case with high forces. In a specially good sample tested by G. Kapp and Prof. Ewing, a magnetic density of 18,000 lines per square centimetre (= 116,000 lines per square inch) was reached with but little more than one-half the magnetising force as is necessary for the same induction in ordinary wrought iron.

(*b*) *Form of Cross-Section.*—The best form of cross-section for a magnet core is undoubtedly that which possesses the smallest circumference for a given area, and this most economical section is the circle. It is, however, often preferable on account of reducing the dimension of the machine perpendicular to the armature shaft, to use cores of other than circular section; in this case either rectangular, elliptical, or oval cores are employed, or several round cores are placed side by side and connected in parallel to each other,

FIG. 105.

magnetically. The latter method, however, is not recommendable for the reason that the magnetising effects of the neighbouring coils partly neutralise each other, because of the currents of equal polarity flowing in opposite lateral directions in the parts of the coils facing each other, as indicated by arrows in Fig. 105. There is consequently a double loss connected with this arrangement, a larger expenditure of copper connected with higher magnet resistance, and decrease of the magnetising effects by mutual influence of the coils.

Besides the forms mentioned, also square cores and hollow magnets of ring section are frequently used.

An idea of the economy of the form of cross-section to be chosen can be formed by means of the following Table LIII., which gives the circumference for unit area of the various forms of cross-sections employed in modern machines, and compares the same with the circumference of the most economical form, the circle. In the case of rectangular and elliptical cores four forms each are considered, the lengths being respectively two, three, four, and eight times the width of the sections. For oval cores three sections are examined, the semicircular end portions being attached to a centre portion formed of one, two, and four adjacent squares respectively. Next come four sections consisting of several round cores in parallel—namely, two, three, four, and eight separate circles. Of hollow cores, finally, five cases are considered, the internal diameter being respectively of one, two, three, four, and eight times the radial thickness of the cross-section.

Hollow magnets are used in some special types, such as shown in Figs. 84, 94, 95, 96, and 100, where large circumferences of the cores are required, but not the total area enclosed by these circumferences, and where the armature or its shaft has to pass through the centre of the magnet.

	" 1:4	4.76	1.34
	" 1:8	5.91	1.67

As to the use of hollow magnets in place of solid ones, Prof. Grotrian states that with weak magnetising forces only the outer layers of the iron next to the winding are magnetised. E. Schulz, however, showed by practical experiments that the magnetisation is exactly proportional to the area of the core section even at the low induction due to the remanent magnetism. From this can be concluded that Prof. Grotrian's results do not apply to the case of dynamo magnets under practical conditions. A. Föppl claims that the theory of Prof. Grotrian is correct—*i.e.*, that the flux gradually penetrates the magnet from its circumference, and that under certain circumstances it may not reach the centre of the core—but he admits that this theory has no practical bearing upon such magnets as are now used in practical dynamo design.

(*c*) *Ratio of Core Area to Cross-Section of Armature.*—The relation between the cross-section of iron in the magnet cores to that of the armature core is a very important one, as on its proper adjustment depends the attainment of maximum output per pound of wire with minimum of iron.

According to tests made at the Cornell University, under the direction of Prof. Dugald C. Jackson, the best area of cross-section of the magnet cores for drum machines is $1\frac{1}{3}$ times that of least cross-section of armature, if the cores are of good wrought iron, or about $2\frac{1}{2}$ times the minimum armature section if cast-iron cores are used.

According to Table XVII., Chapter 12, the maximum core density in ring armatures is from $1\frac{1}{3}$ to $1\frac{2}{3}$ times that of drum armatures; for equal amounts of active wire, therefore, the former require $1\frac{1}{3}$ to $1\frac{2}{3}$ times as great a magnetic flux as the latter, and the cross-sections of the magnet cross consequently have to be taken correspondingly greater in case of ring machines—namely, $1\frac{3}{4}$ to $2\frac{1}{4}$ times the minimum armature section in case of wrought-iron cores, and three to four times the armature section for cast-iron field magnets.

Prof. S. P. Thompson, in his "Manual on Dynamo-Electric Machinery," gives 1·25 for wrought iron and 2·3 for cast iron as the usual ratio in drum machines, and 1·66 and 3 respectively in ring-armature dynamos.

In the experiments conducted by Prof. Jackson, ten different armatures, all of same length and same external diameter, but of different bores, were used in the same field, thus including a range of from ·5 to 1·4 for the ratio of least armature section to core area. The curves obtained show that the total induction through the armature increased quite rapidly when the armature was increased in area from ·5 of that of the magnets to about ·75 of the core area. From ·75 to ·9 there is still an increase of induction with increase of armature section, though comparatively small, and beyond ·9 the increase is of no practical importance.

(44) *Pole-Pieces*—(*a*) *Material.*—The pole-pieces, if the shape and the construction of the magnet frame permits, should be of wrought iron or cast steel in order to reduce their size, and therefore their magnetic leakage, they being of the highest magnetic potential of any part of the magnetic circuit. In forging, care should be taken that the "grain" or texture of the iron runs in the direction of the lines of force. The pole-pieces, however, usually have to embrace from ·7 to ·8 of the armature surface (compare Chapter 1), and are therefore, particularly in the case of bipolar machines, often comparatively large. If in such a case their cross-section, in order to give sufficient mechanical strength, is to be far in excess of the area needed for the magnetic flux, there is no gain in using wrought iron or cast steel, and the pole-pieces should be made of cast iron. The cast iron used should be as soft and free from impurities as possible. It is preferable, whenever practicable, to have it annealed, and, if not too large in bulk, to have it converted into malleable iron; this is especially to be recommended for small machines.

An admixture of aluminium has been found to increase the permeability of the cast iron; by adding $1\frac{1}{2}$ per cent., by weight, of aluminium, the maximum carrying capacity of the cast iron is increased about 5 per cent., by 3 per cent. admixture it is increased 7 per cent., and by adding 6 per cent. of aluminium the induction increases about 9 per cent.; above 7 per cent. of admixture the permeability decreases, and at 12 per cent. addition of aluminium the gain in magnetic conductivity falls down to 7 per cent. From this it follows that an addition of from 6 to 7 per cent., by weight, of aluminium is the proper admixture for the purpose of improving the magnetic qualities of cast iron, which is explained by the fact that the latter percentage is the limit from which up the hardening influence of the aluminium upon the cast iron becomes appreciable.

In large multipolar machines combination frames, consisting of wrought-iron magnet cores, cast-iron yokes, and cast-steel pole-pieces, give excellent results, having the advantages of the high permeability and uniformity in the magnetic qualities of the wrought iron, of cheapness of the cast iron, and of reduction in size of the cast-steel pole-pieces, and being easier to machine, requiring less chipping, and being more easily finished than a magnet frame made entirely of cast steel.

A material which a few years ago was quite a favourite with dynamo-builders, but which since has to a great extent been displaced by the cheaper cast steel, is the so-called "Mitis metal," or cast wrought iron, obtained by melting down scrap wrought iron in crucibles, and by rendering it fluid by the addition of a small quantity of aluminium. The trouble with this material was that a great many extra precautions had to be taken to procure sound castings, and that as a rule the castings were rough and difficult to work on account of their toughness. The magnetic value of Mitis metal differs very little from that of cast steel, its permeability at the inductions used in practice being but a trifle lower than that of the latter.

Edges and sharp corners are to be avoided as much as possible, for if they protrude sufficiently they will act, to a certain extent, as poles, and give cause to a source of loss. In castings, thin projections are apt to chill while being cast, thus making them quite hard and destroying their magnetic qualities; when necessary for mechanical reasons they should therefore be cast quite thick and massive, and may afterwards be planed or turned down to the required size.

(*b*) *Shape.*—The pole-pieces have for their object the trans-

Digitized by Google

mission to the armature of the magnetic flux set up by the field magnet, and the establishment of a magnetic field space around the armature. The shape to be given to them must therefore effect the concentration of the lines of force upon the armature and not their diffusion through the air. This, in general, is achieved by making the polar surfaces as large as possible and bringing them as near to the armature as mechanical considerations permit, and by reducing the leakage areas of the free pole surfaces as much as possible. For practical rules of fixing the distance between the pole corners and the clearance between armature surface and pole-pieces for various kinds and sizes of armatures, see Tables XLVII. and XLVIII., respectively.

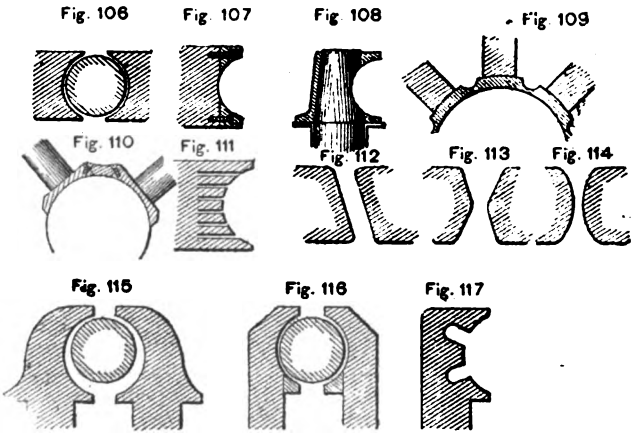
Since Foucault or eddy currents are produced in all metallic masses, either by their motion through magnetic fields or by variations in the strength of electric currents flowing near them, the pole-pieces of a dynamo-electric machine are seats of such currents which form closed circuits of comparatively low resistance, and thereby cause undue heating. These currents are strongest where the changes in the intensity of the magnetic field or of the electric current are the greatest and most sudden; this is the case, and consequently the eddy currents are strongest at those corners of the pole-pieces from which the armature is moved in its rotation, for owing to the distortion of the magnetic field by the revolving armature a density greater than the average is created at the corners where the armature leaves the pole-pieces, and a density smaller than the average at the corners where it enters. In order to reduce and eventually to avoid the generation of these eddy currents in the pole-pieces, as well as in the armature conductors, it is therefore necessary to prevent the crowding of the magnetic lines towards the tips of the pole-pieces, and to so arrange the poles that the magnetic field does not suddenly fall off at the pole corners, but gradually decreases in strength towards the neutral zone. This object in a smooth-armature machine can be attained (1) by gradually increasing the air-gap from the centres of the poles towards the neutral spaces in boring the polar faces to a diameter larger than their least diametrical distance apart, thus giving an elliptical shape to the field space, as illustrated in Fig. 106; (2) by providing wrought-iron pole-pieces with cast-iron tips forming the pole corners and terminating the arcs embraced by the pole faces (see Figs. 107 and 108); or (3) by establishing a magnetic shunt between two neighbouring poles in connecting the pole-pieces either by a cast-iron ring of small sectional area (Dobrowolsky's pole bushing), or by placing thin bridges across the neighbouring pole corners, as shown in Figs. 109 and 110 respectively.

The ellipsity of the field space has the advantage that it confines the lines of force within the sphere of the pole faces by proportionately increasing the reluctance towards the pole corners, thus preventing an increase of the magnetic density at any particular portion of the pole-piece. The application of cast-iron pole tips with wrought iron (or cast steel) pole-pieces, does not prevent the crowding of the lines at the pole corners, but by reason of the low permeability of the cast iron, reduces their density to a figure below that in the wrought iron, and consequently effects a graduation of the field strength near the neutral space, the maximum density being in the wrought iron at the point where the cast-iron tips are joined. In the pole bushing, or its equivalent, the pole bridges, the reach of the magnetic field is greatly increased, the percentage of the polar arc being practically $= 100$, and also a more or less gradual decrease of the field strength at the neutral point is obtained, but the length of the non-sparking space is greatly reduced and thereby its uncertainty increased, thus making the proper setting of the brushes a very difficult operation.

It has also been recommended to laminate both the pole-pieces and the magnet cores in the direction parallel to the armature shaft in order to prevent the production of eddy currents, but this can only be applied to small dynamos, as the additional cost connected with such a lamination in large machines would be in no proportion to the small gain obtained. Besides, there is another reason against lamination; a laminated magnet frame is very sensitive to the fluctuations in the load of the machine, which naturally react upon the magnetic field, and in following these fluctuations an unsteady magnetisation is produced, which, in turn, again tends to increase the fluctuations, causing its variability; while in a solid magnet frame the eddy currents induced by the changes of magnetisation caused by the fluctuations of the load, tend to counteract the very changes producing them, and therefore exercise a steadying influence upon the field, thus reducing the fluctuations in the external circuit of the machine.

An expedient sometimes used, instead of laminating the pole-pieces, is to cut narrow longitudinal slots in the pole-pieces, Fig. 111, thus laminating a portion of the pole-pieces only. These slots at the same time serve to increase the length of the path traversed by the lines of force set up by the action of the armature current, and to thus reduce the armature reaction upon the magnetic field, checking the sparking connected therewith.

When the commutator brushes, after having short-circuited an armature coil, break this short-circuit, the sudden reversal of the current in the same, produced in passing the neutral line of the field, together with the self-induction set up by the extra current on breaking, causes a spark to appear at the brushes which may be considerable, since, in the comparatively low resistance of the short-circuited coil, a small E.M.F. is sufficient to produce a heavy current. If a dynamo, therefore, is otherwise well designed—that is, if the armature is subdivided into a sufficient number of sections, if the field is strong enough so as not to be overpowered by the armature, and if the thickness of the brushes is so chosen as to not short-circuit more than one or two armature sections each simultaneously, and as not to leave one commutator bar before making connection with the next strip—then the sparking at the commutator can be reduced to a practically unappreciable degree by so shaping the pole surfaces as to give a suitable fringe of magnetic field of graduated intensity, thus not only causing the current in the short-circuited coils to die out by degrees, but also compelling the coils to enter the field of opposite polarity gradually. This is achieved by giving the pole corners an oblique, or a double conical, or a hyperbolical form, as illustrated by top views in Figs. 112, 113, and 114 respectively.



For the purpose of counteracting the magnetic pull due to the armature thrust in bipolar machines, see Chapter 24, the pole-pieces are often mounted eccentrically, leaving a smaller gap-space at the side averted from the field-coils than at the side towards the same, Fig. 115; or, in case of wrought-iron or steel pole-pieces, cast-iron pole tips are used at the side towards the exciting coils, and wrought-iron or steel tips at the other, Fig. 116. Both the eccentricity of the pole faces and the cast-iron pole tips, if suitably dimensioned, have the effect of increasing the reluctance of the stronger side of the field in the same proportion as the density rises on account of the dissymmetry of the field, thus making the product of density and permeance the same in both halves.

(To be continued.)

Personal.—Mr. Brooke, the Director-General of Indian Telegraphs, will shortly vacate his appointment, having completed his five years of office. Mr. C. H. Reynolds, Deputy Director-General, will succeed Mr. Brooke as Director-General of Telegraphs, and Mr. P. V. Luke, C.I.E., now director of the construction branch, will succeed Mr. Reynolds as deputy director.

ARC CARBONS AND THE RATING OF ARC LAMPS.*

BY L. B. MARKS.

The report made at the last convention of the National Electric Light Association by a special committee, recommending that what is ordinarily known as a 2,000-c.p. arc lamp shall be considered as one requiring on the average 450 watts for its maintenance, naturally suggests the enquiry as to how far the candle-power produced depends upon the watts consumed, and in the present paper attention will be confined to the part played by the arc carbon in this important relation. It is, of course, well known that the so-called 2,000-c.p. arc really gives a mean candle-power of only 300 to 600, the candle-power at the angle of maximum illumination seldom being greater than 1,200, and often as low as 700. In an elaborate series of comparative tests made by the writer several years ago there was found to be a variation of over 80 per cent. in the candle-power of commercial arc-light carbons consuming the same energy. Quite recently, Prof. W. M. Stine has reported on a number of tests, the results of which show a variation of about 30 per cent.

The difference in the quality of arc carbons was well brought out in a table of some tests made by the author, in which values were determined for the hissing point and the flaming point of various American and foreign products. In order to determine these values, a pair of carbons was placed in a lamp, and burned for 20 to 30 minutes. After the point had been well formed, the carbons were gently brought together until the arc hissed. A voltmeter connected to the terminals gave the potential difference. The lamp was then adjusted for a silent arc, and the mechanism so arranged that the rod was held rigidly. The carbons were then allowed to burn away until they flamed, the voltmeter being carefully watched meanwhile. Before the flaming point was reached the instrument would invariably fluctuate, due to "jumping" of the arc. At the flaming point there was a marked drop in the potential, as indicated by a voltmeter. Great care was taken to secure perfect alignment of the upper and lower carbons. An average of three different tests was made of each pair of carbons. The carbons were all intended for a current of from eight to ten amperes, 9½ amperes being used in the tests. The total length of a pair of carbons was 10in. in each case.

It was found that the range—that is, the difference in volts between the hissing point and the flaming point—varied greatly with different carbons; thus, while one carbon had a range of only 11·4 volts, with another it attained 34 volts. Both of these carbons are sold by representative American manufacturers, the former being a squirted petroleum coke carbon, and the latter a moulded coke carbon. The hissing point of the cored carbon averages over 10 volts lower than the solid. The hissing point of American cored carbons does not vary much from that of foreign, but the range of the latter is fully 10 volts greater than that of the former, and exceeds that of any of the American products tested, cored or solid. In the case of some makes of cored carbons tested it was impossible to measure the hissing point with any degree of accuracy because of the deposition on the negative of small portions of the core thrown out by the positive at low potential differences. The amount and nature of foreign matter in a carbon have much to do with the commercial efficiency of the latter, and determine to a large extent the range of the carbon.

It has been the desire of central-station men to obtain, and the aim of the manufacturer to produce, an absolutely pure petroleum coke carbon, thinking that this would, in a large measure, solve the candle-power question so far as uniformity is concerned. The writer is of the opinion, however, that an absolutely pure coke carbon, if such could be commercially manufactured for arc lamps, would not meet the requirements of central-station practice to-day. Two carbons tested were taken from two batches made with special reference to purity, and it was found that one of them hissed at 53·7 volts and the other at 52. To be operated at maximum efficiency, these carbons would require more than 55 volts at normal current, and under no conditions in practice would they give satisfactory service at less than 55 volts average—fully five volts higher than that of good commercial carbons. In connection with the potential difference required for maximum candle-power in a given case, it is interesting to refer to a test reported by Prof. H. S. Carhart, in which a pair of commercial carbons designed for use on full arc circuits showed a maximum efficiency at about 55 volts. These carbons at 10 amperes and 45 volts gave 450 c.p. Thus, it is of the utmost importance to the carbon manufacturer to test not only the range of his carbons but also the voltage at which they give maximum efficiency. The importance of steadiness in arc lamps has been very well shown by the introduction of cored carbons. Here, again, we are confronted with the question of candle power in relation to the consumption of energy. If we assume that a 450-watt arc gives nominally 500 c.p. with efficient solid carbon sticks, we must make an allowance of at least from 15 to 20 per cent. for reduction in candle power for the same energy, substituting an efficient cored carbon stick. Yet, for indoor illumination the consumer is better satisfied with the cored carbon than with the solid.

It would be entirely out of the question to designate a given current density for commercial light carbons, yet, in attempting to formulate a relation between candle power and energy expended in the lamp, the question of current density must necessarily be considered. Schreihage deduced the law that for homogeneous carbons of the same make the candle-power varies inversely as the diameter. He states that this relation, as is to be expected, is not completely satisfied in the case of the mean horizontal candle-power, especially when the carbons are very small or very large. When we consider that as a means for securing long life, flat carbons and "twin" carbons have been more or less used, we are reminded that in connection with the available candle-power per watt expended in the arc lamp, the shape of the carbon must be given due consideration.

A consideration of alternating-current arcs opens up another field in the discussion of candle-power wherein the carbon point plays an important part. In the commercial operation of alternating-current arcs, cored carbons are almost exclusively used. The constituency of the core has much to do with the efficiency of this type. The comparison of the candle-power of a commercial alternating-current arc with that of a direct-current arc consuming the same energy, as measured at the carbon points, shows that the former gives less illumination than the latter. So important is the relation of the carbon point to efficiency of the alternating-current arc that the substitution of a solid carbon for a cored carbon in this form may reduce the candle-power and decrease the efficiency to such an extent as to make the lamp unmarketable. Thus far we have discussed arcs which burn with free access of oxygen. In the case of enclosed arcs, or those which are operated in small bulbs to which the air has very limited access, the conditions that govern the relation of watts to candle-power for the open-air arc are more or less modified. With enclosed arcs purity of the carbon is very important, and in some applications of these arcs the objections which stand in the way of commercial utilisation of pure carbon electrodes in open-air arcs do not apply.

The importance of details in the manufacture of carbons cannot be over-estimated in the consideration of this subject. With the carbon maker rests the task of supplying a uniform and efficient product; but even with the best carbon product it would seem advisable to discard the term "2,000 c.p." or "1,200 c.p." as applied to arc lamps. Measurement of the wattage, provided for in the resolution of the committee on the rating of arc lamps, appears to be the true solution of the problem. The central station manager will undoubtedly find it to his interest to furnish good carbons, and if he demands them the carbon manufacturer will supply them. To quote Captain William Brophy, "The sooner you sell your light as power, the sooner this trouble will end, and I advise every man in the future to sell his lamp at 450 watts, or whatever is necessary, and bury out of sight the term '2,000 c.p.'"

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom.....	3s. 3d.	6s. 6d.	13s. 0d
Other Places.....	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank.'*

BOUND VOLUMES.

Vol. XIV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

THE DISABILITIES OF YOUTH.

We find that the article which appeared in our issue of February 22 under this title has been interpreted to contain a meaning far more intense than we imagine the author intended. Unfortunately, the editor has been absent from his duties and incapacitated by severe illness for nearly four months, otherwise modifications, which would have been made in the article, did not appear, and as the result some sentences may be twisted to mean that Mr. Crompton, in his position of president of the Institution, animadverted unnecessarily upon the capacity of trade competitors. We do not for a moment suppose that anyone who personally knows Mr. Crompton ever thought this, and as perhaps we have known him as long and as intimately as anyone connected with the industry, we must emphatically repudiate the idea of presidential advocacy of any particular system. Mr. Crompton's view is that the proper conclusion as to what is best is only to be obtained by a careful study of the conditions of the particular case under purview. He is not wedded to any particular system, but is ready to adopt the best as indicated by the particular case after careful examination.

"PREVENTION BETTER THAN CURE."

During the past few months we have had a long list of explosions connected with electric mains. By many it is thought unwise and unpatriotic to the profession to prominently call attention to them. In the opinion of others, not so; they arguing that the continuance of such explosions will lead to disastrous effects upon the industry; and we believe the latter view to be the correct one. Would-be adopters of electric lighting will be dissuaded by interested parties laying stress upon these dangers—dangers, forsooth, not unforeseen—but though avoidable not avoided. The engineers who have designed and carried out high-pressure systems of distribution are greatly to blame for not having had the foresight to prevent any explosion except in cases where the circumstances are not to be controlled. They know, or ought to know, in the first place, that wherever there is a system of gas distribution there is gas leakage, and there is a danger from such leakage getting into ill-ventilated conduits and manholes. These facts should always be glaringly apparent. The application of a light to a gas admixture with air in certain proportions will cause an explosion; if there is little or no air the gas will burn violently, but is in this case perhaps not so dangerous as when forming the admixture. But the gas or mixture will neither explode nor burn without the application of a light. It is all very well to point to certain cases where the light has come from a carelessly-thrown match from the hands of a casual passer-by. These cases are very exceptional. In the first place, there is the gas, which shows lack of proper ventilation. In the second place there is improper ventilation, otherwise the flame could not reach the gas, and this shows bad engineering, or bad workmanship, or bad superintendence, or something equally bad from a responsible source. Most of the explo-

Digitized by Google

sions are undoubtedly caused by electric sparks. It is to the cause of such sparking that we once more desire to direct attention. The death of a bishop by a railway accident is said to be necessary to obtain a beneficial alteration of railway management. What, we may well ask, is necessary to obtain a proper disposition of wires and mains to obtain freedom from sparking? Looking at this matter from the common sense point of view, from the ordinary perception of an onlooker, it is well known that most of the explosions occur at manholes. The conclusion is immediate: there is something wrong about the arrangements of the contacts at the manholes, and if this is the case, then the designer or the carrier-out of the work at these manholes does not know his business. We distinctly assert that the fault is with either designer or worker, and whenever an accident occurs it should be thoroughly examined by experts which of these two should suffer. A short shrift to the man whose original blundering or carelessness caused the accident ought to be the motto of company or municipality. There is no need to jeopardise the lives and limbs of the community at large, and the man who does so ignorantly or wilfully is not a man to hold a position of responsibility. His place is in the backwoods, a hundred miles from his fellow men. But we have not done with our anathemas. For one fault that is found out by means of an explosion there are probably a thousand where a less dangerous discharge is periodically or constantly taking place. Each of these faults means deterioration of something—repair, earlier or later—a money loss to shareholders or ratepayers. Perfection is not attainable, but greater perfection than that too often allowed to pass is attainable, and should be insisted upon. These are young years in the electric light industry as yet, but if the history of mainlaying, alteration and repair could be written, it would create a sensation. Such history cannot be written. It would be libellous, and would blast the reputation of many among us who are thought to approach the immaculate as regards technical knowledge of this kind. The time to improve these details is now. It will be too late when the purchasing public, finding accidents occur in certain quarters and not in others, go blindly for those systems and engineers favoured by lack of accidents. Another succession of explosions similar to those which have been recorded the last few months will cause a revulsion of feeling against particular systems. Hence it is is imperative to thoroughly and exhaustively examine the details of the distribution arrangements. No matter the leakage of gas, the absence of a spark will prevent accident. Too much reliance ought not to be placed on ventilation. That is a palliation, not a prevention. The aim should be absolute prevention. The engineer who relies on ventilation is lost. It means no attempt to grapple with the weak point. It means an incentive to careless workmanship trusting to the system of ventilation adopted to prevent explosion. We suggest the old adage for the motto of all electric engineers, "prevention is better than cure."

ELECTRIC ANNEALING OF ARMOUR-PLATES.

This subject is discussed by Prof. Elihu Thomson in an article in the New York *Electrical Engineer* of March 6. The author states that soon after the introduction of the Harveyised plates it became a great desideratum to be able to locally anneal or soften the chilled surface to a depth sufficient to include all the hard steel at any particular point where it might be necessary to drill the plate in assembling it upon the warship under construction. Various means, such as the application to the surface of the most intense flames of the oxy-hydrogen blowpipe, were found ineffective to accomplish the result desired. The matter coming to the attention of the Thomson Electric Welding Company, was referred to its experts and pronounced by them to be capable of accomplishment by the passage of heavy currents locally through the surface of the plate. A number of experiments with sample pieces of plate did not, however, at first yield the desired results, and it was only by the establishment of a process of working or distinct method that the result could be accomplished. This method was devised by Mr. Hermann Lemp, the electrician of the Welding Company.

The process consists essentially in passing a current between two electrodes placed at a certain distance apart on the plate surface, and thereby heating a portion of the plate to an annealing temperature, after which, by a very gradual and careful diminution of the current, the temperature is slowly lowered, so that the too rapid cooling by conduction of heat to the massive plate-back of the heated portion shall be prevented from acting as a chill upon the heated metal. This provides that during the cooling there shall be a constant and continual application of the heating current and the production of heat, but at a rate which is made less and less, so that the metal back of the hardened surface, which is constantly abstracting heat, may be kept supplied, with the result that the fall of temperature at the heated or annealed spot may be controlled and kept such that no subsequent chilling takes place. The real object of annealing the spots on the armour-plate is, of course, to enable holes to be drilled through the surfaces and screw-threads to be cut into them by tapping, so that the plates themselves can be attached, or have other parts of the ship attached to them.

The apparatus used in the practice of the process consists of a dynamo furnishing alternating currents, these being such as are used in operating electric welding apparatus by the Thomson process. The currents from the dynamo feed the primary of a transformer, which is, in many respects, the same in general construction as a welding transformer. Instead, however, of the secondary terminals ending in clamps, they are simply blocks of copper cooled by water circulation, and separated a certain distance. These blocks are applied to the face of the plate under some pressure, and the current passing between the blocks heats up the metal between them, and here, as in certain welding operations, the fact of the use of alternating currents favours the concentration of the heating effect and the flow of current locally. The self-induction effect or reactance is least when the current flows near the surface of the plate between the electrodes, so that any current which branches from the electrodes and enters deeply into the plate not only has a longer path, but has a path in which the self-induction operates to limit the flow.

In actual practice with the apparatus at the Cramp shipyard it has been found that the results are highly satisfactory, the original apparatus being made to do with facility work in position and under circumstances which was not contemplated in its original construction, and for which other special arrangements were being worked out. The value of the process was more clearly demonstrated in the case of the warship "Massachusetts," which is under construction, as it was found that certain of the armour-plates for the barbettes were hard, or possessed the hard Harveyised skin, where it was absolutely necessary that they should be drilled and tapped. Indeed, it was impossible to properly attach the barbettes without making tapped holes in certain portions of these plates. Strenuous efforts had been made to accomplish the result by blowpipes, and such means did not succeed, while during these

Digitized by Google

trials the building of the upper deck was delayed, until the proper securing of the barbette plates had been accomplished. On the appearance of the electric annealing apparatus at the yards it was soon turned to the accomplishment of this work for the "Massachusetts," so that there was no further need of delaying the work on the ship from the cause mentioned.

ELECTRIC RAILWAYS AND TRAMWAYS IN EUROPE.

Good service has been done by our contemporary *L'Industrie Electrique* in the past in the publication of statistics relating to central stations and electric tramways and railways in Europe. Our contemporary has now printed in its issue of the 10th inst. details of the electric railways and electric tramways in operation, in course of construction, or projected on January 1, 1895. These statistics show that the number of lines worked has increased from 43 in January, 1894, to 70 on the first day of the same month of the present year; that the total length has increased from 189 miles to 434 miles in the same period; that the power of the generating stations has advanced from 10,650 kilowatts to 18,150 kilowatts; and that the number of cars and locomotives has risen from 538 to 1,236.

The accompanying table indicates the total lengths of the lines at work in various countries, together with the number of cars in service, and the kilometrage now being constructed in those countries.

Country.	Lines in operation. Length in kilometres.	Number of cars.	Lines in construction. Length in kilometres.
Germany	366·17	632	94·59
England	68 80	125	34·20
Austro-Hungary	44·90	129	3·75
Belgium	21·70	48	—
Bosnia	—	—	5·60
Spain	14·00	12	—
France	96·26	152	46·00
Italy	18·85	33	22·80
Sweden & Norway	6·50	11	—
Portugal	—	—	12·80
Roumania	5·43	15	—
Russia	10·00	32	—
Servia	10·00	7	—
Switzerland	37·40	40	2·74
	700·01	1,236	222·48

It will be seen from the above figures that Germany heads the list with 366 kilometres of lines; France comes second with 96 kilometres, and England a bad third with 68 kilometres. It is noteworthy that of the 70 lines worked, no less than 55 are operated on the trolley system, eight on the central rail method, four with accumulators, and three on the underground conductor system. Our contemporary gives the maximum gradients as being as great as 10·5 per cent., and up to 35 per cent. where rack rails are also used.

At present 28 lines are being constructed, with a total length exceeding 200 kilometres. It is expected that these lines will be set in operation this year. *L'Industrie Electrique* erroneously gives the name of the Electric Construction Company as the owners of the Liverpool line, instead of the Liverpool Overhead Railway Company. The complete tables can be recommended to those desiring to possess details of towns, contractors, systems adopted, gauge, generators, motors, etc.

STEAM-ENGINE ECONOMY: CONDENSING ENGINES.

A paper on this subject by Mr. Henry Davey, M.I.C.E., was read at the ordinary meeting of the Institution of Civil Engineers on Tuesday, Sir Benjamin Baker, K.C.M.G., vice-president, in the chair.

The author pointed out that the principles upon which the development of the steam-engine, as regards economy of steam, were founded, had been understood in the time of James Watt, who had shown that gain might be expected to result from increased expansion, and had also explained that in order to obtain the full benefit of expansion the steam-cylinder must be maintained at a high temperature. Trevithick, Sims, Grose, and others had perceived that increased expansion, and consequently increased economy, might result from the employment of higher pressures. As early as 1844 the Cornish engine had been, for the steam-pressure then practicable, a more efficient engine than any other subsequently produced. Some Cornish engines at that time produced 1 i.h.p. per hour for a consumption of 19lb. of steam at a boiler pressure of 30lb. per square inch. Their efficiency was thus greater than that of modern triple-expansion engines giving 1 i.h.p. per hour with 13lb. of steam at a pressure of 120lb. per square inch in the boiler. The triple-expansion engine was more economical because it was worked at a higher pressure and at a higher rate of expansion; but it did not utilise the pressure and expansion so efficiently as the Cornish engine had done. A period of 67 years had been required for the development of the principles enumerated by Watt, Trevithick, and Grose; and upwards of 40 years for the reduction of the consumption of steam from 19lb. to 13lb. per i.h.p. per hour, or, in other words, for the diminution of the coal bill by one-third. In these advances no new principle has been applied, and no higher efficiency obtained.

The author had collected many examples of steam-engine trials in which the mean indicator diagrams were available, and the total feed-water per indicated horse-power per hour was known. These he had submitted to analysis to localise the losses. The mean indicator card of a given trial having been selected, a saturation curve was delineated to represent an assumed standard for a jacketed engine, working with the steam-engine cycle, and with no losses. This figure having been completed, the losses which make up the difference between the actual and the standard diagram could be readily separated, and their relative importance ascertained. The "engine efficiency" was expressed as the ratio between the mean pressure of the indicator figure and that of the standard engine diagram. The diagrams being drawn to a scale convenient for the use of the planimeter, the area of the waste spaces could be measured and expressed as a percentage of the full area of the diagram. These waste spaces represented cylinder condensation, etc., including condensation in the jacket, clearances, compression influences being taken into account when they were considerable, and back pressure. Having submitted a considerable number of examples of different types of engines to this method of analysis, the author showed that the economy of steam obtained by modern engines was simply due to increased pressure and increased expansion, and that the engine-efficiency or the percentage of work obtained from steam of a given pressure and given rate of expansion, referred to the standard selected, was lower in modern engines than in the Cornish engine 30 or 40 years ago. It was also seen that the loss in power arising simply from the cooling influence of the cylinder walls was not, in jacketed engines, at all events, so serious as was sometimes supposed. It was stated that the method gave practical results, and enabled defects in the steam distribution to be readily ascertained; also, that the engine efficiency obtainable from a given steam distribution afforded a proper gauge of the value of that mode of distribution in point of possible economy. The average engine efficiencies, ratios of expansion, and initial pressures for the examples given were:—

	Engine efficiency.	Lbs. of steam per I.H.P. per hour.	Rates of expansion.	Initial pressure.
Cornish	73·0	21·0	3·65	33
Single cylinder	66·0	23·5	3·95	76
Compound	64·0	18·5	7·73	84
Triple expansion	64·4	14·8	14·5	138

The best results in individual cases, fully detailed in appendices to the paper, were much higher.

The Cornish cycle had been devised for pumping-engines in the early days of the steam-engine in Cornwall. Its effect was to maintain the working part of the cylinder at a higher temperature than would be the case if the steam were discharged directly into the condenser. It reduced initial condensation, and by this means increased the engine efficiency. The Cornish engine showed the highest engine efficiency, but it had become obsolete with the adoption of high-pressure steam, and of other less cumbersome

Digitized by Google

machines giving superior economy. It embodied, however, the principles of the most advanced modern steam-engine practice. The greater economy of more recent engines resulted from the use of higher pressure and of greater range of expansion. The compound engine utilised the principle of the diminution of the range of temperature in the cylinder which was embodied in the Cornish cycle, but the triple-expansion engine did so more completely. In the compound engine the loss was larger with the Woolf distribution of steam than with the receiver engine, because in the Woolf engine the cylinders were subjected to a greater range of temperature, and there was greater loss of pressure between the cylinders. In an example of the triple-expansion series, given in an appendix, the loss from cylinder condensation was about one half of the total loss, or, say, 14 per cent. of the power represented by the standard diagram. The losses from clearances and back-pressure each amounted to about 7 per cent., so that the total average efficiency was about 70 per cent. The latter losses were nearly constant in well-made engines, and, therefore, the remaining loss of 14 per cent. was the only one which admitted of considerable reduction, unless it could be shown that the assumed diagram showed too low a standard. Pumping-engines, notwithstanding the low speed at which they worked, had always been among the most economical of steam-engines. As previously stated, the Cornish engine, which was a non-rotative engine, gave a higher engine efficiency than any other. The limit of econonomy had, however, been reached, because it could not be worked at a higher steam pressure, nor with a greater ratio of expansion. The Cornish cycle might be made to give increased economy by a method which appeared to have hitherto escaped notice. The steam, which had done its work and had passed the equilibrium valve, possessed considerable pressure and temperature, say, a pressure of 10lb. per square inch and a temperature of 194deg. F. If a connection, having a non-return valve, were made to a feed-water heater from the equilibrium pipe, the feed-water could be heated to, say, 180deg. F. on its way to the boiler. This possible element of economy invested the Cornish cyle with additional importance when the question of steam-engine economy was considered.

The Gilgit Telegraph.—The following message was recently sent by the Director-General of Indian Telegraphs to the superintendent of the Kashmir telegraph division: "Please telegraph to Messrs. Comber and Johnson, of Gurais, Messrs. Dalby and Smith, of Minimerg, and Mr. Higgins, of Astor, that I am watching with great interest the state of communication with Gilgit, and I wish to congratulate them on the courage and determination they show in successfully repairing the line in the face of great difficulties and danger, which I thoroughly appreciate and understand." The *Indian Engineer* states that it was a bold venture to undertake the erecting of an aërial line of wire over the Tragbal and Burzil Passes, and bravely did Mr. Olpherts and his staff carry it out, and in so doing established communication between India and the spot "where three empires meet." Few who read the telegraphed messages from Gilgit are aware of the political importance which attaches to this line of communication, or how essential it is that its efficiency be maintained, and that Dr. Robertson, the political officer at Gilgit, and his little force be kept in constant touch with the Government. In order that this should be done it was not only necessary to erect the line, but also to adopt very special measures for its maintenance, and the restoring of communication after an interruption. It did not require much of the gift of prophecy to say that interruptions would be frequent, and the task of restoring the damaged line, in these storm and snow-swept heights, dangerous in the extreme. For the more ready means of keeping up the line during the severe winter months, it was divided into sections, and besides the regular telegraph station at Astor, two intermediate stations, one at Gurais, at a level of 8,100ft., and the other at Minimerg, an elevation of 9,800ft. above sea-level, were opened.

ZURICH CENTRAL STATION.

Some details have been published in *L'Industrie Electrique* concerning the working of the Zurich central station during 1893. Although somewhat belated, the information is interesting from several points of view. The station contains 10 Henschel-Jonval turbines running at 100 revolutions and transmitting on an average 1,000 h.p. to a main shaft arranged longitudinally in the station. From this shaft are driven seven sets of pumps which, among other duties, feed a reservoir arranged at a height of 150 metres. A second shaft, which is also actuated from the first, drives four alternators (one of which is spare), each of 300 h.p. Two 300-h.p. high-pressure turbines, supplied from the reservoir mentioned, are mounted on the second shaft. The exciting current is furnished by generators driven from a third shaft.

As the station had to be continuously in operation, it would, of course, not be economical to run all the plant during the time of light loads. Consequently a 100-h.p. dynamo, actuated by belt from the main shaft, has now been installed for service during the day. When the demand increases, the 300 h.p. alternators and turbines are thrown in and the small machine stopped. The current is transmitted at a pressure of 2,000 volts by means of three Berthoud and Borel cables, a distance of 1½ miles to the town, when it is transformed down and distributed to consumers.

As a result of measurements made every week it has been possible to ascertain with sufficient exactness the efficiency of each part of the system. The following figures show the efficiency in percentages:

	First half-year.	Second half-year.	Average for the year.
Efficiency of transmission from motors to generators	79·1	86·8	83·0
Efficiency of the generating system without the transmission	69·1	77·7	75·6
Efficiency of the system, including transmission	54·7	67·4	61·1
Efficiency of the distributing system	71·6	74·2	73·0
Total efficiency without transmission	49·5	57·6	54·0
Total efficiency with transmission	39·2	50·0	45·0

Our contemporary mainly attributes the low total efficiency to the losses due to transmitting power from the motors to the alternators, particularly as a day-load machine was not installed in the period under consideration, and to losses in the transformers. At the same time the financial position of the undertaking is considered to be excellent.

ATLANTIC CABLE REPAIRING.

An interesting paper has been read before the Kearsarge Association of Naval Veterans, in Boston, by Captain Samuel Trott, of the s.s. "Minia," the repairing ship of the Anglo-American Telegraph Company. The following extract gives an idea of the amount of repairing required to keep these cables in working order:

From what has already been said you may infer that submarine telegraph cables have only a precarious existence, which is more or less true; therefore every precaution should be taken by those laying them to guard against impending dangers, for when breaks occur in deep water the cost of repairs often amounts to fabulous sums.

Two of the first cables laid in the Atlantic lived about seven and ten years respectively, when they were broken in deep water. Two attempts were made to repair one, and one attempt was made to repair the other. These three expeditions cost in the aggregate about 1,000,000dol.; both cables were then abandoned. A few years later a fault was cut out of another cable in mid-Atlantic at a cost of 400,000dol. Such enormous expenses and repeated failures forced the managing director of the Anglo-American Telegraph Company to look for some more certain and expeditious means of getting his deep-water repairs effected, so toward the end of the year 1883 he decided to equip the "Minia" for this important work (she hitherto having been fitted for shallow water only). Time has

Digitized by Google

fully proved the wisdom of that decision, her record since then being without parallel in the annals of submarine telegraphy, having accomplished about 120 repairs in the last 10 years (and not a single failure to record against her), although many of them were in the deepest water of the Atlantic, the last of which reaching the enormous depth of 2,597 fathoms. This may be considered the "Minia's" greatest achievement, for not only did she have many unforseen difficulties, which seemed almost insurmountable, to contend with, but there was the fact that another ship, nearly double her size, had the previous summer spent the greater part of four months in the attempt and had failed.

There has also during last year been another failure to record by a still larger ship (claimed to be the best equipped for this work of any in existence). Nearly four months were consumed in fruitless efforts. The expense of these two failures may be estimated at not less than 300,000dol. for ships alone, in addition to which must be added the cost of cable required to replace that which had been destroyed by hacking it to pieces in the continued efforts to recover it.

THE MONOCYLIC SYSTEM.*

BY DR. LOUIS BELL.

To the central station man no recent change in engineering practice can have more interest than the renaissance of alternating current work which is now in progress. Truth to tell, until quite recently the alternating current was somewhat under a cloud in the estimation of both station managers and engineers. It had served an immensely useful purpose in the extension of electric lighting to places where it would have been utterly impracticable to instal a direct current system of any sort, on account of the scattered nature of the work. A very large number of stations have been installed on the alternating system, and I am sorry to say that a large proportion of them have been somewhat unsatisfactory, not in their general operation, but in the character of their service and the commercial results. It is quite common to find alternating stations with a plant efficiency considerably below 50 per cent., and in which the regulation is maintained only within, perhaps, about 10 per cent. Under these circumstances it is small wonder that the advocates of the direct current, the uses of which as an engineering problem have been very completely worked out, have been often somewhat violent in their animadversions on alternating currents in general. Nevertheless, in the last two or three years there has been a vast change for the better in alternating practice, a change not yet rapid, but bidding fair to be far-reaching. This change has taken up a three-fold path towards progress:

First, the use of large transformers is becoming more frequent. Next, these transformers are more and more used with systems of secondary mains; and, finally, it is now possible to install an alternating plant that shall be able to operate motors as successfully as can be done with direct current. In ordinary central-station practice the motor service does not usually play a very important part; nevertheless, the ability to run motors is most valuable. It is more profitable, speaking broadly, to sell current for light, for a better price per kilowatt hour can be obtained; at the same time, if motors can be readily furnished, a useful day load can be obtained when it is needed, and the plant becomes the greater service to the community, a thing which, in these days of more or less friction with common councils, is of no small importance. Not only can motors now be successfully worked off alternating circuits, but off a wide variety of such circuits. As yet, however, there is no successful motor for use on the simple alternating system which has, for the most part, been installed in this country. While it is possible to construct a single-phase motor even for 120 to 130 cycles per second, the frequency most used in America, it is at present very doubtful whether such a motor can be made to start and run in a way which will be generally satisfactory. Abroad, where low periodicities are used, better results may be obtained; but, even there, there is a noticeable silence on several important points in describing alternating motor practice. Appearances indicate that, even with the advantage of low frequency, motors for use on simple alternating circuits still start badly, and particularly require enormous currents at the moment of starting; hence the growth of various modified alternating systems, of which the polyphase is the best known, by the use of which it becomes possible to avoid this difficulty entirely, and to work alternating-current motors in every respect as satisfactory as those operated by direct current.

The polyphase motor has solved the problem of securing good motor service with alternating currents in a very complete manner, although at the cost of slight complications, which, while generally over-estimated, are, nevertheless, distasteful to central-station men, especially where the use of such a system would involve an extensive and costly rearrangement of the distribution service. It is the purpose of this paper to call your attention to the various methods of central-station distribution, involving motor service on the alternating-current system, and more especially to a modified single-phase alternating system, which lends itself very readily to a very simple and straightforward distribution for lighting, without sacrificing the excellent motor service, which makes the true polyphase systems so desirable. For all around central-station work the lighting service is of most fundamental importance, and convenience and economy in this particular must, in a vast majority of cases, be the first consideration. Let me invite your attention to this chart, which shows in a diagrammatic manner the general arrangement of various alternating circuits, including those already familiar and the polyphase and monocyclic systems.

First in order, both of time and extended use, comes the simple alternating system, single phase, with an ordinary two-wire distributing circuit. In operating the secondaries of such a system, we run immediately into limitations imposed by the feasible voltage for lamps, limitations which have acted as a brake on alternating-current work, and which are responsible for a good many difficulties in the operation of alternating plants. Opposite the diagram of this circuit I have placed the relative amount of copper required for lighting with such a distribution.

Next comes the alternating circuit modified for Edison three-wire distribution, which is so familiar in its character that it needs no description here. The amount of copper needed, on the supposition that neutral is half the size of either of the others, is, of course, enormously reduced, amounting, as you see, to less than one-third of that needed with the two-wire system; consequently, the secondary main distribution, so important to economical operation, can be carried out with the greatest facility. We are justified at present in saying that neither of these systems lends themselves to the ready operation of motors.

We may next consider the two-phase alternating system worked with four wires, giving, if desired, two separate circuits for each machine. The copper here required is the same as that used with the single phase, and so long as the four wires are kept together motors can be freely operated. Here is assuredly a step in advance. The operation of two separate circuits, however, from a single machine, involves certain complications. In the first place, unless these circuits are balanced as to load, the operation of the system is somewhat difficult to make satisfactory in point of regulation. The circuits themselves have absolutely no influence on each other, but they are derived from the same machine, and with a given excitation of that machine, unless the loss in the two circuits is the same, the voltages must necessarily be different, consequently the generator cannot be compounded for both circuits unless the circuits are balanced. There are three ways out of this difficulty; none of them, unfortunately, are altogether unobjectionable.

In the first place, one can make the loss on the line so small that the difference in voltage due to any reasonable difference in load is of no moment. This can sometimes successfully be done, but more often it involves a very unnecessary cost for copper, and even at its best is likely to give regulation which, although better than that found on most simple alternating systems, is yet not good enough to suit the requirements of the best modern engineering.

* Paper read before the National Electric Light Association, Cleveland.

Digitized by Google

Second, the machine can be compounded for loss on one of the lines, a feeder regulator being used on the other. This practically means hand-regulation of one circuit.

Or, finally, both circuits can be operated by such regulators. In any case, if motors are to be operated, the two phases must be interlinked at least by one wire.

A somewhat simpler two-phase distribution is that shown in the next diagram, where the two phases unite into a common three-wire circuit. The amount of copper here

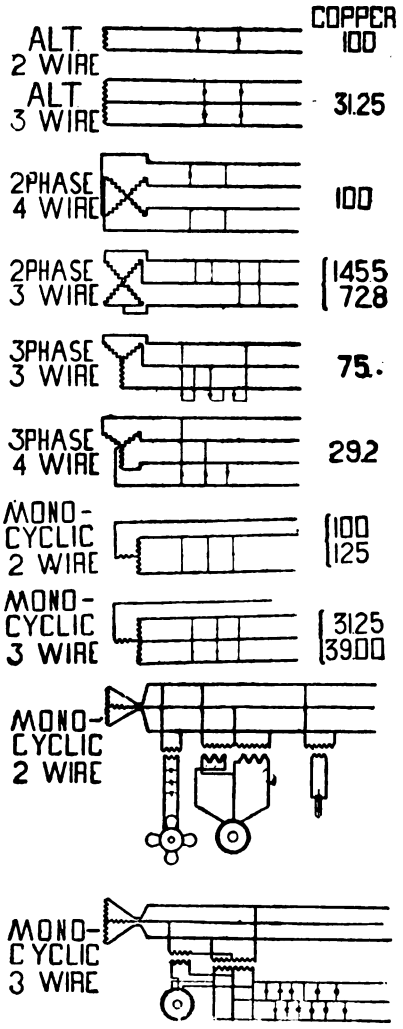

Diagram illustrating different Systems of Distribution.

required differs very materially, according to the limitations of voltage that one chooses to fix. If the maximum voltage of the system is limited to the same maximum voltage used on the single-phase two-wire or two-phase four-wire system, the amount of copper required is very largely increased by the use of the third wire, owing to the fact that the two circuits combined are out of phase with each other by 90deg. The relative amount of copper required here is, as you see, 145·5. If, on the other hand, the question of maximum voltage between wires is neglected and the voltage is determined by the use of lamps of the same voltages as on the other systems, then the amount of copper is materially reduced, being a trifle less than three-fourths of that required on the systems before mentioned. In this case, we neglect the fact of their being an excessive voltage between the outside wires, and connect lamps between the middle wire and the two outside ones much in the manner of an Edison three-wire system, with the exception, of course, that the saving in copper is not anything like the same amount. Such a system allows the distribution of the whole load for lights and power in a single circuit containing only three wires. It therefore avoids the difficulty of regulating two separate circuits. On the other hand, it causes a new and very curious difficulty, owing to the fact that the two combined phases are unsymmetrical with regard to the inductance of the system. The voltages between the middle wire and the two outside wires are unequal, when the systems are equally loaded, by an amount depending on the inductive loss on the line. Consequently, when in balance for regulation, the system is unbalanced as regards the load on the two sides, a condition which, although it may not lead to trouble in some cases, is still a menace to the successful operation of the system, unless the distribution be skillfully engineered. There is, however, the possibility of a noticeable saving in copper.

We may next pass to the three-phase alternating system. The system which corresponds to the two-phase four-wire system I pass by, as the use of three separate circuits would be even more troublesome than that of two, and would have no compensating advantages. The ordinary three-phase circuit is that shown in the figure wherein the three phases are united into three wires and taken everywhere where the motors and lights are wanted. In this case, for the same voltage between wires, the amount of copper demanded is just three-fourths of that demanded for a single-phase two-wire or two-phase four-wire circuit. To compensate for this, there is the possibility of unequal voltages in case the three legs of the circuit are unequally loaded, owing to interaction in transformers and in the generator. So far as inductance on the line is concerned, the system is symmetrical and balanced.

If the load on the three branches is very unequal, as, for example, if one branch is entirely unloaded or very lightly loaded, while the other two are worked to their full capacity, there will be a perceptible unbalancing of the voltage. Experience, however, shows that with anything like the same care in balancing that would apply to an Edison three-wire system, this theoretical difficulty of balance is absolutely negligible. I say this advisedly, as the question has been so often raised that I have taken pains to investigate the conditions in three plants operating lights with reference to this particular thing, and the statement just made is the result of actual practice. It might be thought at first sight that good results could be obtained by combining with either a two-phase or three-phase system the Edison three-wire distribution. As a matter of fact, such a system would be unreasonably complicated with either two or three phases, as any central-station man will readily appreciate, inasmuch as it would be necessary to have two or three wire systems, each balanced, and mutually balanced with respect to each other, covering the territory if motors are to be run, or, at least, interlinked in a somewhat complicated way.

There is, however, a three-phase system which does secure a very great advantage in copper. This is the three-phase four-wire system shown in the figure. It consists of the ordinary three wires employed on the three-phase system, with the addition of a balance wire proceeding from the common connection of the generator or the transformer, and forming a part of the general distribution system. The lights are, as can be seen from the diagram, connected between either of the three-phase wires and the balance wire. Between each of the outside wires there is, therefore, what may be considered two lamps in series, having, however, a phase difference of 120deg. The voltage of transmission, then, between each of the three main wires is 1·73 times the voltage employed in the lamp connected, nearly 200 volts for 110-volt lamps. This necessarily means a large saving in copper, which is still further enhanced by the fact that the three-phase three-wire system requires intrinsically only 75 per cent. of the copper used on the single-phase or direct-current system. The total result with this particular connection is but 29½ per cent. of the copper required on the single-phase system, supposing, as in the Edison three-wire distribution, the neutral wire to be half the size of either of the other. Such a system is in successful use at St. Hyacinthe, Canada, in connection with long secondary mains. The price paid for this saving in copper is the introduction of a fourth wire into the distributing system.

Comparing, then, the lighting distributions on the two and three phase systems, we find that if three wires only are used both save very nearly the same amount of copper. The extreme voltage between wires on the two-phase circuit is, however, considerably greater, and both are liable, but not likely, to become unbalanced.

Digitized by Google

There is this difference, however, that if we are to balance a three-phase system in respect to voltage we need only to see that the load is equally distributed between the three branches. If we are to balance a two-phase three-wire system, we must see that this load is unequally distributed between the three branches by an amount depending on the inductance of the line. We, therefore, see, comparing the polyphase with the single phase system, that the price we have to pay for the privilege of successfully operating motors is a certain amount of complication in circuits, which, while not of great importance in new installations, hinders the ready adaptation of a polyphase system in a plant having already a large number of circuits installed. Attractive as the single phase is in its beautiful simplicity of wiring, we cannot yet successfully run motors from it.

It was for the purpose of preserving that simplicity of distribution which is peculiarly valuable in connection with large central stations, especially those already installed, and joining to this the same ability of running motors found on the polyphase system, that the monocyclic system, to which I am about to call your attention, has been perfected. You see it first in its two-wire form. Here, so far as the lighting distribution is concerned, it is absolutely indentical with any of the alternating systems now installed in simplicity, convenience, and in the amount of copper necessary. The main circuit of the monocyclic machine constitutes a simple single-phase alternator, and, so far as the lighting on the system is concerned, is identical with it, connected in precisely the same way, feeding, if desirable, into the same circuits without change. There is, however, on the armature of the monocyclic machine a supplemental coil, shown on the diagram as connected to the middle point of the main winding on the monocyclic machine, from which a power wire may be led. This need be of but small cross-section, and only has to be carried to those points in the system at which it is desired to operate motors, and, as I shall presently show, this power wire enables one to run motors possessing the same desirable characteristics as the polyphase motors, and, indeed, generally identical with them, without in any way distributing the lighting distribution, except in so far as Ohm's law is a necessary limitation on all combined power and lighting circuits. In the last diagram here we see the same device applied to an Edison three-wire system for the distribution of lights, along with which is carried the same insignificant power wire, which permits the successful operation of motors. The value of the three-wire feature in the distribution of lights is evident, the amount of copper being the same as in an Edison system of the same voltage. With this monocyclic system we can compound the generators for any reasonable loss in the line, and can arrange the lighting system without incurring any troublesome questions of balance, so as to give as good regulation even as can be obtained on a direct-current system. Beyond this we have the power of running motors.

It is instructive to glance over this list of alternating lighting systems to see their relative complexity and advantages. It is especially noteworthy that any and every method of distribution that saves copper introduces in some form or other the question of balance. This is the price we pay for reduction in cost of conductors. It has not seriously interfered with the use of the Edison three-wire system; in fact, those most familiar with that system were the first to make light of the difficulty; nor do I think it stands as a valid objection to the use of the polyphase systems in cases where they are desirable, as none of them are more sensitive in the matter of balance than the Edison three-wire system which is now in such extensive and uniformly successful use. We may further note that in each of the alternating systems, where a very great saving of copper is accomplished, a fourth wire is necessary, at least if both lights and motors are to be operated, in each case, however, of trifling size. Having now looked over the field in general, we may pass to the more minute consideration of the somewhat striking electrical peculiarities of the monocyclic system; peculiarities which, although they do not involve any particular complexity, are yet of decided interest.

The general principle of the system is well shown in this diagram. So far as the main work of the generator is concerned, its winding is closely similar to that of any well-designed alternator. The armature is of the iron-clad type, and the winding is made in machine-wound coils, which are invariably insulated, and can be very readily slipped into place. There is, however, upon the armature a second set of coils of cross-section equivalent to that of the main coil, but composed of comparatively few turns, so that the room taken up on the armature is very small, and owing to the shallowness of the slots necessary to accommodate this second or teaser coil, the output of the machine, considered as a single-phase generator, is not affected. This teaser coil is located with reference to the main coil as shown in the diagram. Its place on the armature is midway between the other coils, and the E.M.F. generated is in a direction at right angles to that of the principal coil. It is evident, now, that if we connect the terminal of this teazer coil with either of the terminals of the main coil we shall get an E.M.F. compounded of the two and in some intermediate direction. In general, by varying the proportions of the two coils, and hence their E.M.Fs., we could obtain a resultant E.M.F. between their terminals having any angle we pleased with either the main or the teaser coil. If, then, wires are taken upon the line from the terminals of the main coil and also from the teaser coil, we can obtain from the main line three E.M.F.'s, two of which are symmetrically situated with reference to the E.M.F. of the teaser coil, and bear to it any phase relation that we please. One of the most convenient arrangements, and that which is most generally adopted, involves such a relation of the E.M.F. of the teaser coil to that of the main coils, that we shall have on the line three E.M.F.'s approximately 60deg. apart. In other words, the resultant E.M.F.'s between teasers and main coils are each 60deg. from the E.M.F. of the teaser coil. Such an arrangement is that shown in the diagram. Under these circumstances, it is clear that if one of these E.M.F.'s were reversed, either in transformers or anywhere in the translating devices, the result would be three E.M.F.'s 120deg. apart, one of them having been turned through an angle of 180deg. Meanwhile, the relation between the power wire, which is connected to the teaser coil and the outside wire has no effect upon the E.M.F. between these outside wires, since the E.M.F. of the main coil itself does not interact with the power wire, except in so far as a portion of it may act with the power wire to form a resultant phase, and E.M.F. for running motors. Consequently, so far as lights are concerned, the two outside wires behave precisely like the leads from any other alternating generator, while so far as motors are concerned we have the power of getting our three E.M.F.'s 120deg. apart, and hence have the same magnetic effect as with a three-phase system. The arrangement of lights and motors with this device is clearly shown in the diagram. It is evident that we can take from the outside wires of the monocyclic system either arc or incandescent lights anywhere and to any extent the capacity of the machine permits, working for the incandescents either two or three wire distribution at option. For a motor, two transformers are connected anywhere we please, one between the power wire and each of the outside wires. At this point the resultant phases come into play, and the necessary reversal of one of the E.M.F.'s is accomplished by the very simple and obvious device of reversing one of the secondaries, as shown in the diagram. To the secondary circuit thus constituted we can connect a standard induction motor, which will start and run as well as if connected to a regular three-phase system, or instead of reversing one of the transformer secondaries we may accomplish the same virtual reversal of the E.M.F. by reversing one of the coils in the motor itself. We therefore have a system which, so far as lights are concerned, is a simple alternating system; so far as motors are concerned, the dynamical equivalent of a polyphase system. With a differently proportioned transformation we could place upon the secondaries two E.M.F.'s 90deg. apart, if necessary, and then run two-phase motors instead of three-phase motors, if there were any object is so doing. Such an arrangement, however, would be less desirable than that of the quasi three-phase system, for the reason that without gaining anything in the motors we should have to

Digitized by Google

generate a larger E.M.F. in the teaser coil, and hence take up more room on the armature with it, perhaps enough to have an effect upon the output of the machine considered as a single phase generator.

It is sufficiently evident that the method shown would not be the only way of getting the same result. For example, in this second diagram a somewhat different arrangement is shown accomplishing precisely the same end. Here our object is to operate secondary mains on the Edison three-wire system, and in connection with them to run motors at any point we please. A large transformer to which the secondary is connected on the three-wire system is therefore installed, and the secondary mains distributed in any manner we please. A second and small transformer, proportioned to the total amount of motor service desired, is connected as shown in the diagram, and the power wire leading from it is taken through the whole or part of the three-wire system. The device is analagous to the arrangement of the generating coils themselves, and the result is the ability to operate a standard induction motor by connecting it anywhere on the three-wire system to the two inside wires and to the power wire. Such an arrangement as this is immensely convenient in distributing power and light in cities where, for example, it is desired to establish an extensive system of secondary mains through Edison tubes or other convenient underground distribution. It is, furthermore, interesting to know that one is not confined to the use of either two or three phase induction motors, since a monocyclic generator connected to the primary circuit makes an excellent synchronous speed without the assistance of a starting motor, in this particular being vastly superior to the pure single phase synchronous machine. But, it may be asked, how about this power wire? In case, for example, of a transmission over a considerable distance before the distributing point is reached, must the power wire be part of the transmission system? In answer, I need only call your attention to the fact that the essential point of the monocyclic system, so far as motors are concerned, is the establishing of an E.M.F. bearing the same relation to the system as is borne by the teaser coil of the generator. Consequently, in case of a transmission plant, the main generators at the distant station may be simple single-phase machines, the subsidiary E.M.F. being furnished by a synchronous motor or similar device at any point in the system; so we might readily have an extensive transmission with a monocyclic machine in the sub-station of such size as is necessary to furnish current for what motors may be upon the system. The power wire would then run only to the sub-station. Another interesting peculiarity of the monocyclic system, and one which is not without importance in case of an extensive power distribution, is the following:

Under ordinary circumstances, induction and synchronous motors are wound so that the counter E.M.F. affects the system in a perfectly symmetrical manner, and the current flows over all the wires with some degree of symmetry in response to the demands of the motors on the system. It is customary, however, in the monocyclic system to employ motors so wound as to throw a high counter E.M.F. into the power wire when the motor is at speed and loaded, thereby reducing the normal current carried over the power wire to a purely nominal amount, and this can evidently be done without sacrificing much in the matter of starting, since at the start all the counter E.M.F.'s in the motors are zero. We have, then, a motor system of a type really peculiar to the monocyclic system, in that each motor will start under the same conditions of impressed E.M.F. as if it were a polyphase motor; while, when at speed and loaded, it would be operating virtually as a single-phase machine. If however, it were overloaded so that it would tend to slow down or stop, sufficient energy would flow over the power wire to bring it back to speed, just as if it were a polyphase machine. This is only one of various interesting ramifications in the system when developed to meet special conditions.

The connections shown in the diagrams, however, are those of the most direct applicability, and probably which would be most extensively used for central-station service. At this point it may be appropriate to ask: What is the disadvantage of such a system? It evidently secures exceedingly marked advantages in the ability to operate the lights on existing circuits or with the simplest possible kind of distribution, and at the same time to run at any point in the system synchronous or induction motors of well-tried and familiar types. The question can be readily answered; in fact, the question is almost obvious. The price which we have to pay for this advantage is the installation of the power wire, which necessarily adds something to the weight of copper in the system and to the trouble of installation. Under all ordinary circumstances the power wire needs to be of trivial cross section compared to that of the other wires, since, as a rule, the energy required for operating the motors from the given central station is small compared with the total capacity of the station; and, further, it is worth remarking that the monocyclic motors, either synchronous or induction, will run perfectly well if the power wire is disconnected after the motor is at a speed operating them as single-phase machines. It is, of course, well-known that the single-phase synchronous motor gives admirable results, and it is also true that a single-phase induction motor can be constructed of excellent efficiency and other electrical properties. The only material difficulty in this case is to get the motor to start with a good torque. The monocyclic connection enables this to be accomplished. After the motor is at speed the power wire becomes no longer necessary to successful operation, so that in spite of the necessary existence of the power wire it is easy to see that the additional amount of copper is not likely to be burdensome in central station operation. It would hardly ever be necessary to install a power wire of more than one-fourth the joint cross-section of the others, as given in the diagram, and generally a much smaller wire will suffice.

I have thus endeavoured in a brief space to give a good working idea of the monocyclic method of combined light and power distribution which has been devised and is urged upon the public as specially adapted for the work of central-station distribution on account of its unique simplicity in practice. As to what has already been done in the installation of such apparatus, a considerable number of these monocyclic generators are in daily use in central stations, for the most part operating over circuits already established and displacing the higher frequency alternators which had been previously used. They are giving excellent results, and the operation of the motors, wherever employed, has been highly satisfactory.

IMPORTANT PATENT DECISION IN THE UNITED STATES.

LAMPS AND TELEPHONES FREE.

In our issue of the 8th inst. we recorded the decision of the United States Supreme Court at Washington in the Bate refrigerator case. The judgment then given affirms the doctrine of the United States Circuit Courts that the term of an American patent expires with that of the foreign patent expiring first, irrespective of the relative dates of domestic and foreign application for a patent on the same invention. Commenting on this decision the New York *Electrical Engineer* says:

The decision seems in no wise to touch the intrinsic merits of Section 4,887—a piece of legislation that has justly incurred the disapproval of the best minds among patent lawyers of distinction (such as the late and lamented Grosvenor P. Lowrey) because of its obvious inequity. But Section 4,887 has now for a long period been uniformly interpreted by the Circuit Courts according to its obvious verbal significance, and vested interests with invested capital have long gone upon the assumption that the law was settled, and that they were secure in their reliance upon the general understanding of its scope and purpose. Now the Supreme Court confirms established rulings of the circuits, and whatever may be thought amiss is left for legislation by Congress. Such legislation, happily, cannot be *ex post facto*, nor invalidate the judgment of our highest tribunal.

While no judicious observer of the history of incandes-

Digitized by Google

cent electric lighting will be disposed to minimise the honour due to Mr. Edison for his achievements, we feel well assured that both electrical experts and the general public will approve the final dissolution of the monopoly sought to be founded upon this questionable patent; while they will at the same time be likely to agree, for the most part, that Section 4,887 is an absurd provision, and that an American inventor who has applied for a domestic patent before he has applied for a foreign patent is merely unfortunate and not derelict if the foreign patent issues first.

From the point of view of electrical industry in general it is gratifying that the manufacture of incandescent lamps will be henceforth free, and that those firms and companies which, relying upon the long delay of the owners of the Edison patent in seeking to enforce their claims, as well as upon their confessed uncertainty as to the life of their patent, have gone into the business in good faith and have made good lamps, can now expand their work, assure adequate competition, and secure to themselves some reward for their efforts.

PHŒNIX FIRE OFFICE RULES FOR INSTALLATIONS OF ELECTRIC HEATING AND COOKING.

In our issue of March 8, in describing the electric radiators adopted at the Vaudeville Theatre, reference was made to the set of rules drawn up by Mr. Musgrave Heaphy, of the Phœnix Fire Office, for observance in cases where electric heating appliances are proposed to be installed. These rules, which will be applicable to future work of this kind, we are enabled to reproduce, by permission of Mr. Heaphy, together with the regulations to be observed in installations of electric cooking apparatus.

Electric Heating.

When any building or portion of a building is to be heated by electricity, the system and arrangements must be such as meet the approval of the technical adviser to the fire office. The same general electrical safeguards must be taken with regard to the installation as are required by the rules for an electric light installation, so far as they apply, but with the addition of such other safeguards as are stated here, or may be considered requisite by the technical adviser to the fire office. The same general safeguards for security from fire will be required with regard to the radiators, etc., that would be considered necessary by the fire office if the radiators, instead of being heated by electricity, were heated to a like temperature by other means. No electrical radiator to be heated to a higher temperature than would be allowed by the fire office for other kinds of heating apparatus.

All radiators must be fixed at such safe distance from woodwork and other combustible substances as may be required by the fire office. No radiator to be fixed in roofs, or in any position or place that may be objected to. Every radiator should be protected by its own separate cut-outs. All radiators should be fixed to, or stand upon, approved fireproof insulators. All sockets and plugs should be incombustible; they must be to the approval of the technical adviser to the fire office. No sockets will be allowed in any place nor in any risk that he may consider undesirable. The use of floor sockets is not desirable; when they are employed, the connections must be sweated into thimbles, they must be efficiently protected against mechanical injury, from damp, and other injurious influences. Every socket should be so constructed that the contacts are automatically covered when the plug is removed.

The main conductors, and all principal branches, must have a switch and cut-out on each conductor. The conductors for supplying current to the radiators must be attached to proper terminals of large carrying capacity. No conductor to be unencased without permission. The insulation upon any unencased conductor must be of special character, and have very strong coverings. No conductors to be so placed that they will be exposed to mechanical injury or to undue heat from the radiators. All work and materials to be of the highest character, and to the satisfaction of the technical adviser to the fire office. The entire installation (including the insulation resistance of the whole work, both with regard to earth and between conductors) must also be to his satisfaction. With regard to hazardous risks other special precautions may be required; these, of course, may vary according to the nature and circumstances of the particular risk. In hazardous risks, the electric heating installation should be distinct from any electric light installation that may be on the premises. Before commencing any work, therefore, in a hazardous risk, enquiry should be made at the fire office and their permission first obtained.

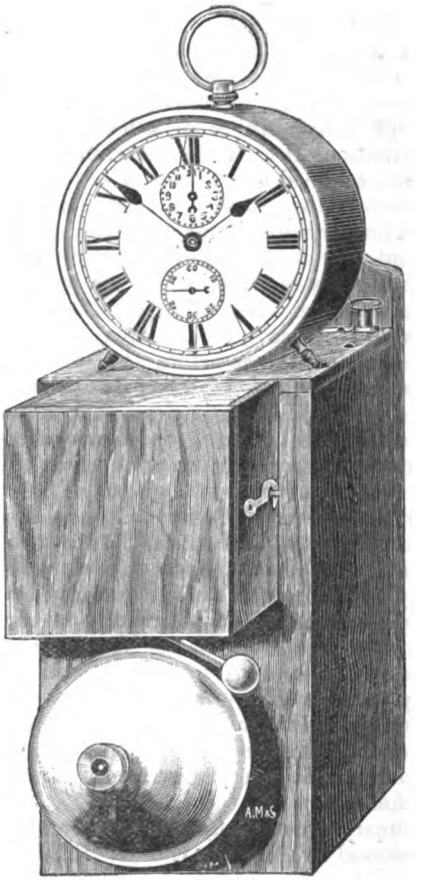
Electric Cooking.

The same general rules must be observed as for electric heating, so far as they apply. Every oven, stove, or other apparatus should be protected by its own separate cut-outs. The greatest care must be exercised in arranging the conductors that there is no possibility of any of them becoming unduly heated, either by proximity or contact with any of the apparatus, or from other causes. Care must also be taken that none of the electrical work is liable to mechanical injury. Special care must be taken with regard to insulation. This refers not only to the installation generally, but to the cooking apparatus itself.

With regard to the cooking apparatus, the same general safeguards must be taken with regard to security from danger of fire that would be considered necessary by the fire office if the apparatus were heated to similar temperatures by other means, and this applies also to the positions of the apparatus, methods of fixing, distance from and protection of woodwork or other combustible materials, etc. The whole of the work to be to the satisfaction of the technical adviser to the fire office.

"XL" ELECTRIC ALARM CLOCK.

The annexed illustration shows the "XL" electric alarm clock which has been placed on the market by Messrs. A. Mayer and Son, of 127, Aldersgate-street, E.C. The



clock is simple in action and use, and may be connected to any existing bell installation. It can be operated either by an E. S. dry battery or a Leclanché cell, and is claimed to be the cheapest obtainable.

LONDON COUNTY COUNCIL COMMITTEES.

PASTE THIS UP FOR REFERENCE.

We give below the names of the members of the Finance, Highways, and Works Committees of the London County Council, appointed on Tuesday.

First comes the Finance Committee, who will be remembered particularly by local authorities in the Metropolis in regard to recommendations concerning the periods under which loans for electric lighting purposes will be granted.

London electric supply companies, and local authorities having their own electric light stations, will bear in mind the Highways Committee in connection with the restrictions imposed in the past in regard to the laying of underground mains and the construction of transformer-chambers. But with Earl Russell and Mr. W. Haydon as members of the new committee, it is to be hoped that the latter will be taught how to act more sensibly than in the past.

Digitized by Google

The Works Committee is fortunate in having the company of Mr. Harry Marks, who will be remembered as one of the most formidable opponents of the old Metropolitan Board of Works, and who is credited with having brought about the collapse of that body May the Works Committee be given a few lessons by the new blood just introduced.

The committees are composed as follows:

Finance Committee.—W. H. Bruce, C. H. Campbell, B. L. Cohen, Sir J. C. Dimsdale, Sir H. B. T. Farquhar, C. Harrison, S. B. Heward, A. Hoare, Hon. E. Hubbard, Sir John Hutton, Sir J. Lubbock, E. Spicer, Lord Welby, Sir A. Wilson, T. McKinnon Wood.

Highways Committee.—J. A. Baker, B. Cooper, T. L. Corbett, P. F. C. Costelloe, J. S. Fletcher, W. Haydon, N. W. Hubbard, Edwin Jones, Earl of Onslow, T. Reed, Earl Russell, W. C. Steadman, J. Thornton, T. B. Westacott.

Works Committee.—R. C. Antrobus, G. Bicker-Caarten, J. Burns, T. Catmur, J. Dixon, E. B. Ellice-Clark, W. H. Fox, W. Goodman, E. A. Goulding, A. Hoare, Hon. L. R. Holland, A. Humphrey, Robert Lyon, H. H. Marks, Viscount Mountmorres, W. C. Steadman, H. R. Taylor, J. Thornton, H. Ward, E. White.

LEGAL INTELLIGENCE.

EISLER v. MARSHALL AND ANOTHER.

This action, which was heard before Mr. Justice Matthew without a jury in the Queen's Bench Division last week, was brought to recover damages from the defendant for having failed to underwrite shares in the Scottish House-to-House Electricity Company, Limited, pursuant to an agreement of August, 1892, made between them and the plaintiff. The agreement provided that, in consideration of the plaintiff taking 2,000 £5 shares in the company, the defendants, by themselves or others, undertook to take and pay for 4,000 shares in the company on or before October 31, 1892, and that a penalty of £500 was to be paid by way of damages by the party failing to perform his part of the agreement to the party performing his. On October 31, 1892, no shares had been applied for. On December 15, 1892, the company was advertised, a prospectus issued, and the plaintiff sent in his application for 2,000 shares. On December 23, 1892, the plaintiff withdrew his application before allotment. He then went to Scotland to see the directors and Mr. M'Leod, the promoter of the Company. The result of that was that the plaintiff sanctioned the Company going to allotment and renewed his application, and had allotted to him 2,000 shares, upon which he paid £955. No money was forthcoming from the defendants, who failed to get the shares underwritten, and the Company was abandoned. The plaintiff thereupon commenced an action for rescission of his contract to take shares, which ended in a compromise, the plaintiff being freed from further liability in respect of them. He then commenced his action against the defendants to recover £1,000 damages under the agreement of August, 1892. It was contended on the part of the defendants that the date fixed for carrying out the agreement was October 31, 1892, and that the plaintiff had put an end to the agreement by cancelling his application for shares.

Mr. Justice Mathew, in giving judgment, said the question was whether the contract of August, 1892, was restored or revived by either party having waved any of its terms. That was a question of fact. The defendants were to provide £10,000 each by October 31 to pay the contractors of the company. The date came and went and nothing had been done. The company had been formed only in the sense that it had been registered, but no prospectus had been issued. At the end of October it was not possible for any of the parties to carry out the agreement. The plaintiff was convinced that things would not do and withdrew his application for an allotment. The plaintiff saw the directors, and it was said it was not right to go to allotment. The promoter then told plaintiff that he could provide £10,000 within a week, and upon that the plaintiff sanctioned the company going to allotment. The plaintiff had no right to call upon the defendants to subscribe for shares. The action was misconceived and had failed, and there must be judgment for the defendants, with costs.

COMPANIES' MEETINGS AND REPORTS.

SCARBOROUGH ELECTRIC SUPPLY COMPANY, LIMITED.

The third ordinary general meeting was held at Scarborough on Tuesday, Mr. G. Alderson Smith, the chairman, presiding.

The **Chairman** moved the adoption of the report and statement of accounts, which recommended that the credit balance of £418 on revenue account be carried forward. The report was, he considered, extremely satisfactory, considering that this was the Company's first year's work. During the first six months of the Company's operations, they worked at a loss month by month; but in the second six months they not only cancelled that loss, but earned the profit stated. There was a steady progression towards a dividend which could not be far distant. They had spent £5,385 additional on capital account during the year, including buildings £822, mains £2,808, transformers £1,033, and meters £563; and, as to the future, they were committed to the establishment of a new alternator at a cost of £750, the erection of a foreman's cottage, and the conversion of a super-heater into an economiser. It appeared advisable for the proper extension of the Company to seek the introduction of new capital, which, he imagined, would easily be forthcoming. They had now 7¼ miles of mains, which constituted one of their heaviest charges, but they were bound to go on progressing in this direction.

Mr. John Bell Simpson seconded the motion, speaking hopefully of the prospects of the Company, and declaring that in 10 years' time the electric light companies would be supplying most of the illuminating power in use.

In reply to **Mr. J. Sinfield**, **Mr. A. A. Campbell Swinton**, managing director, said that the Company had commenced with a charge of 7d. per Board of Trade unit, whereas some small companies charged 8d. or 9d. At present the charges made by the Scarborough company varied according to the quantity consumed, the different rates being 6½d., 6¼., 6d., and 5¾d., and in addition to that 5 per cent. discount was allowed for cash. He believed those were the lowest prices known, excepting at Newcastle-on-Tyne, and in the case of consumers of thousands of pounds' worth by certain large establishments in London. They were certainly lower than those of any company of the same size. The cost of production during the year had been: coal, 1·87d.; oil, waste, and stores, ·3d.; wages, 1·57d.; repairs, ·47d.; rents, taxes, insurance, ·19d.; salaries and other expenses, ·44d.; total, 4·87d., or nearly 5d. per unit, which was sold at an average price of 6d. That did not leave a very wide margin of profit, but the cost would not increase *pro ratio* with the output, so that, with an increased consumption, the profit would be more than correspondingly large.

The report was adopted. Mr. John Dale, Mr. John Bell Simpson, and Mr. J. W. Woodall, retiring directors, were re-elected.

BRITISH INSULATED WIRE COMPANY, LIMITED.

The ordinary general meeting of this Company was held at the offices of the Company, in Prescot, on the 13th inst., Mr. W. Harriner Brigg presiding over a good attendance of shareholders.

The directors in their fourth annual report and balance-sheet stated that the amount of the net profit, including the balance of £363. 14s. 4d. from last year, was £5,751. 2s. 9d., after writing off £3,500 balance of formation expenses, and making a liberal allowance for depreciation of buildings, machinery, patents, etc.

The directors recommended a dividend of 7 per cent. on the ordinary shares, absorbing £5,067. 12s. 8d. (a dividend of 7 per cent. on the preference shares having already been paid to December 31 last), leaving a balance of £683. 10s. 1d. to be carried forward to next year.

During the year the turnover of the Company has more than doubled, and the Company now numbers amongst its customers a large proportion of the principal cities and towns, and some of the chief railway companies in the kingdom.

The report was adopted, and Mr. Thos. Snape, M.P., having been elected a director, the meeting terminated with the usual vote of thanks to the chairman.

W. T. HENLEY'S TELEGRAPH WORKS COMPANY, LIMITED.

Directors: Sydney Gedge, Esq., chairman; Major-General Geo. Hutchinson, C.E., C.S.I.; Frederick Newton, Esq.; R. J. Jenkins, Esq., C.E.; the Hon. Randolph Stewart; George Sutton, Esq, managing-director.

Report of the directors to be presented to the shareholders at the ordinary general meeting to be held at the Company's offices on Friday, March 22, 1895, at 12.30 p.m.

The annexed accounts show that a net profit has been made of £16,455. 13s. 11d. After payment of interest and income-tax, making allowance for depreciation of plant and the expenses of issuing the 4½ per cent. mortgage debenture stock, there remains £11,819. 8s. 3d., to which must be added £5,187. 14s. 2d. brought forward from last year. Deducting £1,050, the half-year's dividend on preference shares paid in October last, there remains at disposal a balance of £15,957. 2s. 5d. The directors have added £2,180. 9s. 2d. to the reserve fund, and they propose the payment of a further half-year's dividend on the preference shares at the rate of 7 per cent. per annum, and a dividend for the year at the rate of 6 per cent. free of income-tax, on the ordinary shares; these payments together absorb £5,152. 4s., and leave a balance of £8,624. 9s. 3d. to be carried forward. In the month of August last, an issue was made of £50,000 4½ per cent. mortgage debenture stock. The whole amount has been issued and the proceeds applied to paying off all existing mortgages and debentures, and to providing additional buildings, plant, and working capital. All expenses in connection with the issue of this new stock have been charged against the revenue of the year. The Company has not had during the year a single large contract for submarine cables, but the large increase in its general business has enabled a dividend to be paid of 6 per cent. instead of 5 per cent. as heretofore. The directors heartily congratulate the shareholders on this result and on the general satisfactory position of the Company. The directors who retire on this occasion, in accordance with the provisions of the articles of association, are Mr. R. J. Jenkins, C.E., and the Hon. Randolph Stewart, who, being eligible, offer themselves for re-election. The auditors, Messrs. Ball, Baker, Deed, Cornish, and Co., retire, and, being eligible, offer themselves for re-election.

ROCKHAMPTON GAS AND COKE COMPANY, LIMITED.

We have received a copy of the report and accounts of the directors of this Queensland Company for the half-year ended December 31, 1894. The report, which was presented to a meeting of the shareholders on the 7th ult., is given in abstract below.

The directors are able to report an improvement upon the preceding half year, due to an increased demand for the electric current and to the reduced expenses in connection with the electrical operations. The rigid economy practised by the townspeople in their gaslighting has naturally had a marked effect upon the gas consumption for the half-year, and although the number of customers continues to increase, the total consumption is considerably lower than in former years. With more prosperous times and the ordinary development of the town the directors expect to see a recurrence to the freer demand for gas. The gas operations show a profit of £1,672. 2s. The electrical operations show a profit for the half-year of £183. 6s. 2d., which has gone towards the payment of the £300 interest upon the whole of the Company's debentures charged to the electric light operations, leaving a difference of £116. 13s. 10d. represented in the debit balance of the profit and loss account of this section of the Company's business. The net profit for the whole of the Company's business is £1,555. 8s. 2d.

During the half-year premiums amounting to £465 have been received from new shares, and this profit has, in accordance with the usual custom, been placed direct to the credit of the reserve fund for the equalisation of dividends, which now stands at £574. 5s. 10d. As the Company has as much money as it requires at present, the directors thought it advisable for the time being to stop the sale of the new shares, to prevent an accumulation of capital which would only be earning the present small bank interest and which would represent a loss of the difference between the rate allowed by the bank and the dividend paid by the Company to the shareholders. The directors recommend the appropriation of £293. 3s. 6d. from the reserve fund for the equalisation of dividends, to permit of the payment of a dividend at the rate of 8 per cent. per annum upon the ordinary shares, and 9 per cent. per annum upon the preference shares, amounting to £1,848. 11s. 8d., free of dividend tax. The large demand for coke and tar continues, and it is satisfactory to know that the stocks of these two articles are consequently low. The whole of the general reserve fund, amounting to £2,898. 17s. 2d., is now invested as a fixed deposit with the Bank of Australasia. This fund is in future to be devoted exclusively to the maintenance and improvement of the Company's plant. The prospects of the Company are bright, and justify the directors in anticipating an encouraging development in the Company's operations, and to ensure this, strenuous efforts are being used to keep down expenses. The agreement between the electrical engineer and the Company terminated in October last. Another electrical engineer to take his place is now on his way out in the s.s. "Ophir."

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Brazil.—The Municipal Council of S. Joao d'El Rey, Minas Geraes, are asking for tenders for lighting the town by electricity.

St. Pancras.—Particulars are given in our advertisement columns of tenders required by the St. Pancras Vestry for the construction of a sub-station.

Norwich.—The Town Council require by April 2 tenders for the supply of two Galloway boilers and the installation of electric light fittings at the new baths.

Stowmarket.—The Urban District Council require by April 15 tenders for lighting the streets of Stowmarket from August 15 next to May 15, 1896, and also for lighting the post office clock. Particulars may be had of Mr. S. Prentice, clerk.

Bradford.—The Corporation require tenders by the 28th inst. for the construction and delivery of two steam dynamos. Specification may be had on application to Mr. Baynes, Electricity Department, Town Hall, Bradford, on payment of £1. 1s.

West Ham.—The Town Council require by the 26th inst. tenders for the supply of a 12 h.p. nom. portable steam-engine. Specification and further particulars may be obtained of Mr. Lewis Angell, borough engineer, Town Hall, Stratford, E., on payment of £1.

Llanelly.—The Borough District Council desire by the 25th inst. plans, designs, specifications, and estimates of cost for the supply and installation of electrical plant and machinery, including street lamps and laying down mains. Plans of the district can be obtained from Mr. George Watkeys, C.E., borough surveyor, Llanelly.

Nottingham.—The Corporation invite by the 28th inst. tenders for two Lancashire steel boilers (26ft. long and 7ft. diameter) and fittings, and placing same on their seats at the public baths, Sneinton. Plans may be seen and copies of the specification obtained at the office of Mr. Arthur Brown, M.I.C.E., borough engineer, on payment of £2. 2s.

Worcester.—The Corporation invite tenders by April 6 for wiring Victoria Institute. Copies of specification may be obtained from the architects, Messrs. Simpson and Milner-Allen, 10, New-inn, Strand, London, W.C., accompanied by a deposit of £1. 1s. Plans of the lighting system may be seen at their offices, and on the works. Tenders are to be delivered at the offices of the architects.

Madrid.—The Electricity Supply Company for Spain, Limited, invite tenders for the supply and erection of certain machinery, etc., for the extension of their electricity works in Madrid. The plan of buildings and statement of requirements, with terms and conditions of tender, may be obtained at the office of the company, 15, St. Helen's-place, London, E.C., or of Mr. Robert Hammond, the consulting engineer, Ormonde House, Great Trinity-lane, London, E.C., on payment of £1. 1s. Tenders must be addressed to Mr. P. A. Latham, secretary, by the 27th inst.

Digitized by Google

RESULTS OF TENDERS.

Yarmouth.—The Town Council have accepted the tender of Messrs. Crompton and Co. for 40 joint boxes at £1. 17s. 6d. per box.

Birmingham.—The Town Council have accepted the tender of Messrs. D. and G. Graham, of Glasgow, for the supply of electrical plant for the new technical school.

Hanley.—The Town Council have accepted, at £4,036, the tender of Messrs. S. Z. de Ferranti, Limited, for the supply of additional generating plant at the central station.

Brentford.—The tender of Messrs. Harrison, Coles, and Co., of Richmond, has been accepted, at £131. 10s., for supplying and fixing telephones and electric calls in connection with the fire brigade, for the Urban District Council, and at £100 for maintenance for 10 years.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—The receipts for the past week were £3,605.

Croydon.—The Chamber of Commerce are investigating the question as to the probable demand for light in the compulsory area.

Halifax.—The electric light is to be adopted in the new police offices and court-house to be formed of the existing infirmary buildings.

Folkestone.—It is stated that the Dover Electric Supply Company are prepared to transmit electrical energy for the lighting of Folkestone.

Chelsea Electricity Supply Company, Limited.—Letters of allotment and regret for the issue of 4½ per cent. debenture stock have been posted.

Wimbledon.—Messrs. Drake and Gorham have been successful in obtaining the contract for the electric lighting of Mr. Bishop's new house, Wimbledon.

Electric Construction Company.—The registered address of the Electric Construction Company, Limited, is now Dashwood House, 9, Old Broad-street, E.C.

Medical Electrical Institute.—In this case Mr. Justice Vaughan Williams on Wednesday made a compulsory order, on the petition of James Willing the younger.

Morecambe.—The Urban District Council have approved of the plans of the Morecambe Electric Light and Power Company for the erection of a new generating station in Moss-lane.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 17th inst. amounted to £975, as compared with £707 in the corresponding week of last year.

Payment of Coupons.—The Bank of Montreal will pay on the 1st prox. the coupons then due of the 4½ per cent. debenture loan for £120,000 of the Royal Electric Company of Montreal.

Yarmouth.—The Town Council have appointed Mr. A. W. Ranken, who has acted as clerk of works during the construction of the central station, electrical engineer at £175 per annum.

Hull.—The Electric Lighting Committee of the Corporation think that another boiler and engine should be installed for meeting the anticipated increase in the demand by next winter.

Chemical Syndicate.—The Chemical Syndicate, Limited, has been formed, with a nominal capital of £6,000, for the purpose of acquiring a new process for manufacturing cyanide of potassium.

Whitehaven.—It was mentioned to the Town Council last week that the two new engines and dynamos ordered by the late Board were now in position, and that within a fortnight they would be at work.

Southend.—The Town Council having resolved to try incandescent gas lamps in several parts of the borough, have also appointed a committee to consider the desirability of installing the electric light.

Dover.—The supply of the electric light from the company's station is shortly to be commenced, and it is expected that the lighting of the sea-front by means of arc lamps will be completed by Easter.

Birmingham Central Tramways Company.—An order has been made by Mr. Justice Stirling confirming a special resolution of the Birmingham Central Tramways Company, Limited, for the reduction of its capital.

Worcester.—The Board of Guardians have authorised Mr. Rowe, architect, to prepare specifications for the lighting of the male ward block and workshops by electricity, and to obtain tenders for carrying out the work.

Liverpool.—The Lighting (Special) Committee of the Corporation met on Monday to again consider the proposed purchase of the Electric Supply Company's undertaking. The matter was again deferred for further consideration.

City and South London Railway.—The receipts of the Company for the week ended March 17 were £912, against £926 for the corresponding week of 1894, or a decrease of £14. The total receipts for the current period of the present half-year are £10,823, against £10,400 in the corresponding period of 1894, an increase of £423.

Sale of Electrical Plant.—As will be seen by our advertisement columns, Messrs. Percy Huddleston and Co. will sell by public auction on Tuesday and Wednesday next the stock of a cable manufacturer and electrical engineer at Dawson's, Croft Mill, Greengate, Salford.

Conway.—The Town Council last week had under consideration an application from the electric tramway company for permission to extend their proposed line from Deganwy by way of the Morfa to Conway. It was agreed to give assent to the scheme, subject to certain conditions.

Moss Side.—The Finance Committee having found that there is only a sum of about £240, after allowing for all contingencies, to provide electric lighting for the Princess-road Schools, the School Board have resolved that in view of this fact the electric lighting scheme be abandoned.

Heywood.—The gas manager last week presented a report on electric lighting to the Gas Committee. In reply to a member, Alderman Firth (the chairman of the Gas Committee) said that enquiries had been made, but as yet the committee could not recommend electric lighting for Heywood.

Direct Spanish Telegraph Company.—The directors have decided to recommend the payment of a dividend at the rate of 10 per cent. per annum on the preference shares, and a dividend, free of income tax, at the rate of 4 per cent. per annum on the ordinary shares for the half-year ended December 31 last.

Wakefield.—Some months ago between £700 and £800 was expended in the renovation and enlargement of the large organ at the Cathedral. A further improvement is now contemplated, and Mr. Speight, of Leeds, has been requested to send in an estimate of the cost of a new blowing apparatus by hydraulic or other means.

Newmarket.—The Urban District Council have received a letter from the Board of Trade notifying that the electric light company have not taken up their powers of introducing the light into the town, and that they proposed to revoke the order. The Council passed a resolution that they would be glad to have the order revoked.

Private Lighting.—The electric light is being installed in Archbishop's House, Westminster. The work has been entrusted to Mr. Frederic Berlyn, of Messrs. Roger Dawson, Limited, of 63, Berners-street, London. A feature of this installation will be an ingenious arrangement of switches, by which a considerable saving will be effected over gas in this spacious building.

Dublin.—Referring to the note in our last issue concerning the reconstruction of the Southern District Tramway Company's line, the British Insulated Wire Company, of Prescot, inform us that they have obtained the order for the whole of the high-pressure triple concentric cables for the tramway, being 11½ miles in length, and suited for working at 2,500 volts with triphase current.

Monmouth.—The Town Council on Monday accepted the revised portion of Mr. Lailey's plans, etc., for drainage within the borough. The total estimated cost of drainage and electric light is £18,537. It was resolved to apply to the Local Government Board for power to borrow £20,000 for the purpose of carrying out the combined scheme and paying off preliminary expenses already incurred.

Cleckheaton.—The subscribers to the National Telephone Company in Cleckheaton were notified on Wednesday that the directors of the company had decided that Cleckheaton shall be a joint area, as between Bradford and Dewsbury, and that the Cleckheaton subscribers may have the option of electing to be in either the Bradford or Dewsbury area, free connection being granted in the chosen area. The arrangement is to come into force on the 1st prox.

Marshall v. the South Staffordshire Tramways.—The arguments in this appeal from the decision of Mr. Justice Kekewich were resumed on Wednesday before Lord Halsbury and Lords Justices Lindley and Smith. The important point raised is whether the holders of mortgage debentures issued by a tramway company are in the same position as the holders of mortgage debentures issued by a railway company. Their Lordships took time to consider their judgment.

Scarborough.—During the past year the Scarborough Electric Supply Company have supplied electrical energy to the amount of 89,727 Board of Trade units at a gross revenue, including meter rent of £2,277. There is a net balance of £418, which the directors consider a satisfactory result on the first year's working. They propose carrying this amount forward. Mr. G. Alderson-Smith has been elected chairman of the company, vice Lieutenant-Colonel Steble, resigned, and Mr. J. E. Ellis, M.P., has been elected a director to fill the vacancy on the Board.

Damage to a Telegraph Cable.—Mr. Justice Day and Trinity Masters have found for the defendant shipowners in the action brought by the Direct Spanish Telegraph Company, Limited, against the owners of the ss. "Caloric," which, dragging her anchor in the Bay of Bilbao, when it was hove, was found entangled by two cables, one of which parted, and the other the ship's carpenter cut, The Court held that the master followed the common practice, and so was justified, and was not guilty of negligence in respect to the ground he selected for his anchorage.

Sunbury (Surrey.)—The Urban District Council have received a letter from the Local Government Board in reference to the land needed for the outfall sewerage works. Mr. Hyde mentioned at a meeting of the Council last week that he thought if they could get a better scheme they should pay £300 more to have the enquiry over again rather than pay £2,000 a year for the working expenses. He had been told of a scheme to deal with the sewage by electricity which would save the town £1,500 to £2,000 a year. It was a scheme formulated by Mr. South, of Staines. It was decided to hold a special meeting, at which Mr. South is to be invited to attend.

Digitized by Google

Bristol.—The Sanitary Committee last week received a communication from the secretary of the Electrical Committee enclosing certain resolutions passed by the committee with reference to the proposed electric tramway at Old Market-street. The committee recommended the Sanitary Committee that it was not advisable to utilise the poles of the tramways company for arc lamps. They also recommended that the tramway posts be put at a distance of 12 yards from the arc-lamp posts. The third resolution stated that the committee were prepared to recommend a suitable person as clerk of the works.

Appointments Vacant.—An engineer is required at Mullingar Asylum. Candidates must be competent to take charge of the boilers, engines, dynamos, and general heating apparatus. The salary offered is £70 per anum, all found including clothing. Applications are to be sent to the medical superintendent, District Asylum, Mullingar, by 25th inst.—A clerk of works is required at once for the Bristol electric tramway. Only those experienced in tramway or railway work and having high references need apply. Applications are to be sent by letter to the Secretary, Bristol Tramways and Carriage Company, Limited, Bristol.

Leeds.—The town hall and municipal buildings are now lighted with electric light, supplied by the Yorkshire House to House Company. Hitherto the current used for this purpose has been produced by an engine and dynamo in the basement of the municipal buildings. On Saturday evening the work commenced of connecting the lights in the two buildings with the mains of the electric lighting company, and this was completed on Sunday evening. Afterwards the current was turned on. The Corporation are paying the company 4d. per unit for the supply, this being about the same as it had hitherto cost them to produce with their own plant.

Bury.—An enquiry was held on Wednesday by Mr. T. Coddrington, C.E., with reference to an application by the Corporation to borrow £3,000 for an enlargement of the destructor, and £30,000 for electric lighting purposes. The Town Clerk (Mr. Haslam) said that power to supply the electric light was obtained in 1890. It had been decided to adopt the direct-current low-pressure system. The borough surveyor (Mr. Cartwright) gave further particulars. He said there would be three engines, three dynamos, with accumulators, etc. They would be able to supply 12,000 lamps and leave room for extensions; but machinery for half that amount of light was only being put in now.

Recent Failure.—A statement has been issued by the Official Receiver under a receiving order granted on the 26th ult. against Mr. J. Lewis Young. It appears that by profession the debtor is an electrical engineer, and that he joined his brother in partnership in 1891 in an established business carried on at 60, Ludgate-hill, paying £400 for a half-share. The liabilities are returned in the accounts at £3,108, of which £2,958 appear to be unsecured, with available assets nil, debts to the amount of £620 being returned as bad. The debtor attributes his insolvency to stoppage of his businesses in consequence of actions brought against him for alleged infringement of patent rights, and a subsequent adverse verdict which involved him in heavy claims for law costs.

Macclesfield.—The Board of Guardians have received a letter from Mr. S. V. Clirehugh, of Manchester, stating that it was proposed by a syndicate, to which he was consulting engineer, to establish at Macclesfield a central station for the purpose of supplying electricity to certain public buildings in the vicinity. To that end the infirmary and Parkside Asylum had been approached. He wished to know whether they would be prepared to consider the question of taking a supply were such a station erected. The charge, he added, would be equivalent to gas at 2s. 6d. per 1,000. The cost of fitting the workhouse with necessary wires, etc., would be about 25s. per light. He asked for an interview with the object of enabling him to explain the scheme more fully. The letter has been referred to the House Committee to have an interview with the writer.

The City.—The Streets Committee of the City Commission of Sewers were asked on Tuesday by Mr. Wallace whether the Streets Committee would present a report shortly on the subject of the telephone tubes. Mr. Morton reminded his colleagues that the whole question had been referred to a Select Committee of the House of Commons and that it was hardly likely that the committee could present a report while the matter was *sub judice*. He regretted to know that the City was not represented on that committee, although he had done his best to get it represented. He considered that the City, which was primarily concerned, had been very badly treated. He thought, however, that the Streets Committee should make some representation to Parliament through the Remembrancer. The Streets Committee have instructed the Remembrancer to take some action in the matter.

Whitechapel, E.—The District Board on Monday had presented to them by the Streets Committee its long expected report on the question of lighting the district by electricity. Some three years ago the Board obtained a provisional order. With the help of Prof. Robinson three schemes have been prepared. The committee recommend the Board to light the compulsory area at an estimated outlay of £44,500. The central station will be at the destructor-yard. The matter was discussed shortly at the Board meeting on Monday and adjourned. Prof. Robinson has been appointed electrical engineer to the Board for the purpose of carrying out the work. The committee sent circulars to 89 of the largest ratepayers, asking them whether, in the event of the Board providing the electric light, they would be likely to use it. Forty-six replied in the affirmative, nine in the negative, nine were doubtful, and 25 did not reply.

Llandrindod.—The Urban District Council last week discussed the question of public lighting. The Chairman strongly advocated the adoption of the electric light. He had recently noticed little villages on the Continent with the electric light in the houses of the poor. It would be ridiculous to think of gas, particularly in a health resort. Mr. Jones was in favour of starting gasworks, and was of opinion that a small gas plant could be made to pay at once. The clerk read extracts from a report made in November, 1893, by Mr. Preece, of Bradford, upon the cost of lighting the district by electricity, and suggested that the Council should obtain a provisional order, and make an agreement with the company to construct the works and carry the scheme into effect. He saw no reason why the Council should not rid themselves of responsibility in this matter. The idea seemed to meet with general approval, and it was resolved to invite Mr. Preece to come down and address a ratepayer's meeting on the subject.

Southport.—The Southport Town Council met on Tuesday for the purpose of considering resolutions passed by the Electricity Committee to the effect that application be made to the Local Government Board for sanction to borrow £3,000 for street-lighting, and £6,000 for the purpose of extending the works. Councillor Hesford moved the adoption of the resolutions, and Councillor Todd seconded the motion. Alderman Griffiths was of opinion that the Electricity Committee were not wise in limiting themselves to £3,000 for arc lighting. If they were to lay a cable to the extent of this estimate it would only provide for 40 lamps. He was in favour of their borrowing a sufficient sum to meet all requirements for the next four or five years. Councillor Hulme thought Southport could have no better advertisement than that which would be afforded by the fact that their promenade and streets were lighted by electricity. Councillor Travis thought they ought to borrow £12,000 instead of £6,000, so that the Council could have it within its power to grant money to the Electricity Committee when need arose. Eventually, on the suggestion of Councillor Travis, Councillor Hesford moved that for street-lighting and the benefit of private consumers respectively, they ask for sanction to borrow £3,500 and £12,000. The resolutions were carried.

Hanley.—The Town Council on Tuesday adopted a report of the Electric Lighting Sub-Committee, who recommended that the street lamps should be charged at the rate of £16 per lamp per annum, and that the charge for the same during the past half-year should be £170. They further recommended that the borough surveyor (Mr. J. Lobley) and electrical engineer (Mr. Cottam) should provide in the scheme they are preparing for the extension of the mains, for cables being laid in Broad-street, Snow-hill, Howard-place, Stoke-road to the park, Hope-street, Etruria-road to Hanley Station, Clough-street, Market-street to Bath-street, Birch-terrace, Jasper-street, and Regent-road, and for street lighting only, the following roads on the Park Estate: Matlock-street, Harding-street, Outer Circle street, Cleveland-road, Victoria-road, Park-avenue, and Avenue-road. The committee also submitted a statement of accounts up to December 31, 1894, in connection with the electric light undertaking, which showed receipts £1,574 and expenditure £916, leaving a profit of £658, out of which £627 had been appropriated for interest, and £31 for the reserve fund. The committee also recommended that the tender of Messrs. S. Z. de Ferranti, Limited, for generating machinery at the electricity works, amounting to £4,036 be accepted, and that application be made to the Local Government Board for sanction to borrow £5,000, repayable in 25 years.

Hampstead.—The Electric Lighting Committee recommended the Vestry, last week, to employ their own engineer (Mr. Chattock) to superintend the carrying out of all future work in connection with electric lighting in the parish. Mr. Thwaites, chairman of the committee, formally moved the adoption of the recommendation, and Mr. Adams seconded the motion. Mr. Underwood moved, as an amendment, that the Vestry should employ Mr. Preece to carry out all future installations in the parish until the next election of vestrymen, and that his remuneration be 4 per cent. on the outlay. If the motion were carried, he remarked, the Vestry would be acting in as mean and shabby a manner as possible. Mr. Bence seconded the amendment. Mr. Ryalls stated that, including the hundred guineas received for the preparation of the scheme for lighting the parish, Mr. Preece had up to the present time received between £1,300 and £1,400. They could not be accused of shabby conduct in view of that fact. Mr. Thwaites said that when the installation reached 16,000 private lamps a profit would probably be shown. At present there were 6,194 lamps connected. The amendment was lost, only six members voting for it. Mr. Elliott then moved, and Mr. Reed seconded, that the recommendation be referred back to the committee, the latter remarking that Mr. Chattock had not yet been asked if he would undertake this new responsibility. This amendment was also lost, and the recommendation of the committee was adopted. The Vestry decided to ask Mr. Preece if he will act as consulting engineer to the Vestry until the next annual election of vestrymen.

Leicester.—The Town Council last week adopted a report bearing on the financial position of the electric lighting department. In moving the acceptance of the report, Alderman Lennard said that they had passed through the most trying stages—the initiatory stages of a new department—and at the end of that time they placed before the Council a balance-sheet which, after placing £130 to the reserve fund (practically profit), only showed a loss of £190 up to Christmas last. That amount the committee did not propose to take out of the rates, but to carry it over to next year. He believed that in the first year of complete working

Digitized by Google

they would show a profit on the prices they now charged. The balance-sheet showed that they had raised the full amount authorised on capital account—namely, £42,748—but up to the present they had only spent £18,882 of that The total receipts on revenue account had been £382, and the gross profit £263. On the expenditure side of the account he would only refer to one item, that of the fuel, which came out at the low figure of £14 15s. This was due to the fact that the fuel they used was practically refuse, only a degree better than the absolute refuse which they used as fuel in the chemical department of the gasworks. As to the price for light, they were at present charging 6d. per unit, but the committee hoped that before 1895 ended they would be able to ask permission to reduce the charge to 5d. At present the highest demand on the department had been only one-sixth of their capacity, but the committee were satisfied that on the present price charged they were paying their way, and with an increased consumption they hoped to be able to reduce the price.

Fareham.—The electric lighting question was further discussed last week at an adjourned meeting of the Urban District Council. The point under consideration had reference to the letter received from Mr. Graham Whitlock, solicitor to the Fareham Electric Lighting Company, calling upon the Council to fulfil the contract to purchase the undertaking, made by the late Local Board, and so to avoid litigation. The Chairman said that on the 1st inst. a resolution was moved by himself and seconded by Mr. Etherington, that Mr. Whitlock's letter should lie on the table, and that this was under discussion when the Board adjourned. Mr. Abraham moved an amendment to the effect that counsel should be consulted as to the liability of the Council under the contract. Mr. Batchelor seconded the amendment. Mr. Blake said it would be much against the desire and the inclination of the Electric Light Company to go to law against the town of Fareham. Mr. Smith had said that his statement that the late Local Board agreed to purchase the undertaking of the company for £5,000 was untrue, but he would refer the Council to the minutes. He complained that the chairman had not asked the opinion of the clerk with regard to the contents of Mr. Whitlock's letter, adding that the business of the Board had been neglected in that respect. The Council would be bound to have counsel's opinion within the next 14 days, even if the amendment was not carried. Mr. Smith was of opinion that it was now too late to obtain counsel's opinion. The Local Board should have obtained it before the alleged contract was signed. The chairman having summed up, the amendment was put and rejected, and the resolution was declared carried.

Edinburgh.—The Lord Provost's Committee of the Town Council have had under consideration the motion by Councillor Douglas to consider and report whether any and if so what steps should be taken in the interest of public safety to secure that any faults in gas mains and service pipes shall be detected and removed without delay, and to provide against any dangers likely to result from insufficient piping in connection with the introduction of the electric light into the city. The committee have thought it advisable to refer the motion in the first place to the Electric Light Sub-Committee in order that a report may be made on the subject. The minutes of the Works Committee, presented to a meeting of the Edinburgh and Leith Commissioners on Monday, showed that the convener, Bailie Kinloch Anderson, with the engineers, had had a conference with the convener of the Electric Light Sub-Committee, Prof. Kennedy, Mr. Monkhouse, and the Town Clerk, on the subject of electric light and gas escapes. After full discussion, it had been arranged that the Electric Light Sub-Committee should adopt certain further precautions for the prevention of explosions—the Gas Commissioners, on the other hand, undertaking to continue their present methods for discovering and remedying escapes. Councillor Waterston said it would be well if the convener of the Works Committee were to state precisely what precautions had been taken to prevent a recurrence of the explosions. Bailie Kinloch Anderson said he did not think that the public required to be instructed as to the precautionary methods adopted if they had the assurance of the Commissioners that the utmost precautions were being taken for the public safety. The commission was directly interested in the matter, because if gas was escaping they lost money. It was therefore their interest to detect escapes at once, and both the electrical engineers and their own engineers were at one in the opinion that the further precautions to be taken would be sufficient to meet the case. The steps that the electrical engineers were to take would prevent the accumulation of gas in the culverts in any large quantity, and the precautions that the Commissioners' engineers had adopted would obviate the risk of any further explosions.

Birmingham.—The question of accepting a tender for the electric lighting of the new technical school, to which we have referred in previous issues, again came up for consideration at a meeting of the Town Council on Tuesday, when Mr. Martineau presented the report of the Technical School Committee, and moved that the committee should be empowered to expend £6,080 in providing electric light fittings and motive power at the new technical school. Since the proceedings at the last Council meeting, Mr. Martineau said the committee had again reconsidered the matter, but having on a former occasion given the most attentive, conscientious, and deliberate consideration to the subject, they found they were unable to come to any other conclusion than that which was before the Council. Alderman Johnson seconded the motion. Mr. Bradley moved as an amendment that the following rider be added: "That the committee be and are hereby instructed to accept the lowest tender submitted under specifications originally issued to a select number of firms." That, he said, was the third attempt on his part to prevent the Council from deliberately sanctioning what he regarded as an injustice. He contended that the second specifications ought not to have been issued. If any amendments were required upon the original tender they could have been made by arrangement. He thought the committee had made a dead set against a particular firm, and he did not think it right that the Council should have either to sanction a wrong or accept the resignation of the committee. Mr. Bishop seconded the amendment. Alderman Parker, in defending the action of the committee, pointed out that the original tenders were made on the condition that the committee were not bound to accept the lowest or any of them. Fresh specifications were thought desirable. Tenders were invited, and Messrs. Fowler, in tendering again, actually acquiesced in the principle of discarding the previous tenders, which were really dead. In the second contract they were above many of the firms in the trade, and if there was any injustice it would be in accepting one of the higher tenders in the second competition. Those below Messrs. Fowler would then have real cause for complaint. Mr. Reynolds and Mr. Parkes both supported the resolution of the committee, the latter gentleman protesting against Mr. Bradley's assertion that the committee made a dead set against any firm. Mr. Coombs contended that the committee had acted in the truest and highest interests of the City, and he thought they were entitled to the consideration of the Council in the matter. Mr. Bisseker said that if any member wanted to see where the specifications had been changed, he should be delighted to show them. The principal part of the change was made in the fittings for the engineers' department, which had been condemned as impracticable by Dr. Sumpner, the new professor, and several other experts to whom he had submitted them. He argued that the committee had a perfect right to alter any specification they chose, inasmuch as the matter had not been voted upon in the Council. It was better to amend the matter in committee than to have it brought up in the Council and sent back to the committee for revision. The vote was then taken, and 17 were in favour of the amendment, whilst there were 35 against it, and one member remained neutral. The amendment was therefore lost, and the original resolution was carried. The report was afterwards approved.

Cardiff.—The Lighting Committee of the Town Council had presented to them on Tuesday two reports on the electric lighting of the town. Mr. W. H. Massey, the consulting engineer, stated in his report that the private lighting had given great satisfaction since the current was first turned on, and as he understood that applications for the light were steadily coming in, they might soon expect an increased load for one of the large engines and dynamos. On the last occasion of his visiting the Cardiff works, on the night of the 8th inst., the maximum load, including the arc lighting, was not quite equal to one-half of the full capacity of the one set of machinery, and the average throughout the run did not exceed one-third of that capacity. Deducting the portion due to the arc lighting, the average amount of current supplied to private consumers between 4 p.m. and 12 midnight was only equivalent to that required for about 600 40-watt (so-called 8 c.p.) lamps, whilst the greater number of lamps in use during a comparatively short period that evening scarcely reached 1,200. Under those somewhat unfavourable conditions the engines continued to work well and very economically, too, if the figures he saw relating to coal consumption, etc., were accurate. He hoped before long, when the machinery was fairly loaded, to have an opportunity of making some efficiency tests, of which the committee should have full details. Mr. Massey went on to say that the street-lighting had not been so successful, but the nature and extent of the failures since January 1 had been very grossly exaggerated, and the mishaps were generally due to shortcomings elsewhere, and not in the system of rectifiers introduced in Cardiff. The lamps were placed alternately, and the failure of one half of the entire system would still leave the streets fairly well lighted. The contractors were now fitting improved automatic cut-outs to each lamp, and when the defect in the governor and regulating gear of the engines had been remedied, Cardiff would have a very perfect system of street-lighting. With regard to what steps were necessary to carry out and perfect the system, it would be necessary to provide a supply of current for private consumers during the whole 24 hours, and the two small compound engines and dynamos might have been used for that purpose during the past four or five months. Mr. W. Harpur, the borough engineer, in his report stated that he could not give sufficient reason for the long delays in delivering the different parts of the machinery, the only excuse which he had heard adduced being the prolonged coal strike, which prevented the making of the iron, etc., requisite for the manufacture of the machinery. He believed, however, that the committee would have done wisely, and a great deal of time would have been saved, had they taken his advice and appointed a competent person to have superintended on their behalf the erection of the plant. With regard to the present condition of the plant, all the machinery, etc., contracted for in the original contracts had been delivered, and had been running and supplying energy to private consumers since November 17 last. A few more small accessories were still necessary for the efficient working of the station. The plant being in one or two respects novel for electric lighting purposes, experiments were necessary for proving its adaptability to their requirements. The condenser had given trouble from time to time, and some difficulty had also been experienced in getting the rectifiers to run properly, and even at the present time they were not running satisfactorily on the compound engines. Before these engines could be accepted as satisfactory something would have to be done to remedy the defect. As far as he could judge, the alternators, transformers, and mains were in every sense satisfactory. It was decided, on the motion of the Mayor, to print the two reports.

Digitized by Google

Mr. Massey said he agreed with everything in Mr. Harpur's statement. The committee then proceeded to appoint a superintendent for the works. Three applicants had been asked to appear before the committee. Ultimately Mr. Neville Appelbee, of 4, Stafford-place, Buckingham-gate, London, was appointed. The salary attaching to the post is £200 per year.

PROVISIONAL PATENTS, 1895.

MARCH 11.

5086. **Improved means for connecting the branch wires of an electric lamp to the main conductors, or for other similar purposes.** Henry Schuster Cowx, 4, St. Ann's-square, Manchester.

5099. **An improved electric gas-lighter.** Friedrich Martin Kass, 70, Wellington-street, Glasgow. (Complete specification.)

5102. **Improvements in electric arc lamps for optical lanterns, projectors, and the like.** Arthur Barrett, 2, St. Mary's-passage, Cambridge.

5131 **Improvements in and relating to telephone apparatus.** William Bell Robeson, 45, Southampton-buildings, Chancery-lane, London.

5137. **Improvements in the construction and working of electrical transformers.** Sebastian Ziani de Ferranti, 27, Charterhouse-square, London.

MARCH 12.

5189. **Improvement in telephonic communication.** Thomas Tomlinson, 6, Fontenoy-terrace, Bray.

5196. **Improvements in thermo-electric generators.** Harry Barringer Cox, 46, Lincoln's-inn fields, London. (Complete specification.)

5199. **Improvements in telephone transmitters and in telephone receivers.** Charles Jackson, 7, Staple-inn, London.

5205. **Process for the production of electrode plates for electric collectors.** Carl Luckow, 5, Metzerstrasse, Cologne. (Complete specification.)

5231. **Improvements in or relating to the automatic regulation of the current carrying capacity of fuses for electric currents.** Francis Gibson Baily, 323, High Holborn, London.

5236. **Improvements in apparatus for starting electric motors.** Henry Willock Ravenshaw and Easton, Anderson, and Goolden, Limited, 1, Queen Victoria-street, London.

5269. **Improvements in mechanism for forming battery plates.** Charles John Reed, 45, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents, &c., Act, 1883, Sec. 103, September 12, 1894, being date of application in United States.) (Complete specification.)

MARCH 13.

5309. **Electric alarm for clocks.** William Taylor, 3, John-street, Bush Hill Park, Enfield.

5311. **Improvements in incandescence lamps.** Alfred Réné Upward, 150, Holland-road, Kensington, London.

5313. **Improvements in ohmmeters and other electrical measuring instruments.** Charles William Scott Crawley and Alfred Soames, 16, Red Lion-street, Clerkenwell, London. (Complete specification.)

5326. **An electrical safety stop for hydraulic motors.** William Carter and the Hydraulic Engineering Company, Limited, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

5331. **Improvements in recording wattmeters.** James Devonshire, 24, Southampton-buildings, Chancery-lane, London. (Walter C. Fish, United States.) (Complete specification.)

5336. **Improvements in armatures of dynamo-electric machines.** Alexander Bewicke Blackburn and Thomas Large Boyden, 47, Lincoln's-inn-fields, London.

MARCH 14.

5385. **Improvements in telephony and telephonic apparatus.** Maxymilian Kotyra, 24, Queen Victoria-street, London.

5392. **Improvements in treating metallic tape used in the manufacture of submarine electric telegraph cables and for other purposes.** The Birmingham Small-Arms and Metal Company, Limited, and William Henry Greenwood, 7, Staple-inn, London.

5410. **Improvements in or relating to the means of protecting electrical conductors, water-pipes, and the like.** John Augustine Kingdon, 29, Marlborough-hill, London.

5428. **Electric transmitting thermometer.** Francis Napier Denison, 4, South-street, Finsbury, London. (Complete specification.)

MARCH 15.

5451. **Improvements in self-recording electric meters.** Arthur Wright, 26, Park-crescent, Brighton.

5515. **Improvements in electric measuring instruments.** Rookes Evelyn Bell Crompton, 55, Chancery-lane, London.

5521. **Improvements in electric couplings.** Octavius March, 40, Chancery-lane, London.

MARCH 16.

5568. **Improvements in alternating-current arc lamps.** William Phillips Thompson, 6, Lord-street, Liverpool. (Wilhelm Mathiesen, Germany.) (Complete specification.)

5596. **Improved construction and arrangement of commutators for dynamos.** Samuel Jevons, 166, Fleet-street, London.

5601. **Improvements in signalling and electric searchlight apparatus.** Sherard Osborn Cowper-Coles and Leonard William North Hickley, 45, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1891.

3191. **Distributing electricity.** Von Dolivo-Dobrowolsky and others. (Second edition.)

1892.

19874. **Regulating electrical energy to lamps, etc.** Davis and Collins. (Second edition.)

1893.

10,942. **Voltaic batteries.** Walker and Wilkins. (Second edition.)

22053. **Secondary batteries.** Doubleday. (Sussmann.)

1894.

3469. **Dynamo-electric, etc., machines.** Pöschmann and Hanisch.

6057. **Electrical conductors.** Edmunds.

6721. **Signalling between police stations and call-boxes.** National Telephone Company, Limited, and Eggar.

7801. **Electrolytical apparatus.** Kellner.

7955. **Electric measuring instruments.** Thomson.

7994. **Electrolytic cell.** De Pass. (Thofehrn.)

8813. **Electric conductors.** Siemens Bros., and Co., Limited, and Dreselhorst.

23970. **Electric conductors.** A. and J. M. Anderson.

24625. **Electric safety appliance for railroads.** Orcutt.

1895.

1164. **Telegraph apparatus.** Damaskinos.

1544. **Electrical conductors.** Lewis.

NOTES.

Rangoon.—It is proposed to light the bank of the river at Rangoon by electricity.

State Telephony.—The telephone network of the Vienna Private Telegraph Company has now passed into the possession of the Government.

French Physical Society.—The annual meeting of the Société Française de Physique will take place on April 16 and 17 at 44, Rue de Rennes, Paris.

Lighting Quarantine Stations.—Powerful electric lamps are to be provided at the quarantine station at New York for the inspection of immigrants at night.

Gas Explosions.—As a set-off to the explosions in electric light manholes, *L'Energie Electrique* recently published a list of explosions of gas in different buildings.

Cable Repairs.—The "Pouyer-Quertier" has left Saint-Nazaire in order to repair the two secondary cables connecting the island of Saint-Pierre and North America.

Electro-Harmonic Society.—A smoking concert, the programme of which appeared in our issue of the 15th inst., will take place this (Friday) evening at the St. James's Hall Restaurant.

Pooling in the United States.—Arrangements are being made, a correspondent telegraphs, for "pooling" to prevent ruinous prices by the Westinghouse, Edison, and other great electric companies.

Wiring by a Supply Company.—An experiment is about to be made by the Berliner Electricitätswerke in the direction of wiring houses for consumers, in addition to the supply of electrical energy.

Laying of New Mains.—The London County Council have sanctioned the laying of new mains by the House-to-House Company, the Hampstead Vestry, the Westminster Company, the St. Pancras Vestry, and the Notting Hill Company.

Institution of Civil Engineers.—The annual banquet of this institution was held on Wednesday. Sir R. Rawlinson presided, and among the speakers were the Duke of Cambridge, the American Ambassador, and Lord Salisbury.

The Hodgkin Prize.—Lord Rayleigh and Prof. Ramsay have submitted to the Smithsonian Institute a joint essay regarding argon in the competition for the Hodgkin prize of 10,000 dollars for discoveries regarding the atmosphere.

Students of the Institution.—A paper by Mr. C. V. Drysdale, on "The Practical Measurement of Self-Induction," will be read at a students' meeting of the Institution of Electrical Engineers to be held next Friday, the 5th prox., at 28, Victoria-street, S.W.

Municipal Electrical Course.—The Paris Town Council have referred to the Fourth Commission a proposal made by M. P. Viguier, that a course in electricity should be established at the Hotel de Ville for the benefit of those employed in connection with the Hotel de Ville.

City Electric Athletic Club. — The winter entertainments of the City Electric Athletic Club (in connection with the City of London Electric Lighting Company, Limited) were brought to a conclusion on Tuesday by a Bohemian concert at the St. James's Hall, Regent-street.

Reduction in Chelsea.—The Chelsea Electricity Supply Company announce that, commencing with July 1st next, they will supply current at 6d. per Board of Trade unit with a sliding scale to 5d. for lighting purposes, and at 4d. per Board of Trade unit (by separate meter) for motors, cooking, and heating.

Exhibition at Brussels.—An international exhibition, under the patronage of the Government, is to be held in Brussels in 1897. It will comprise the applications of the arts, science, and industry; and electricity will form a prominent feature. The exhibition, which will be opened in May, will terminate in six months.

Liverpool Engineering Society.—The twelfth ordinary meeting of the present session will be held at the Royal Institution, Colquitt-street, on Wednesday next, Ayril 3, at 8 o'clock, when a paper on "A Scheme for the Distribution of Energy in Towns" will be read by Mr. Francis G. Baily, M.A., A.M.I.E.E., and Dr. C. A. Kohn, Ph.D., B.Sc.

The Recent Accident at Bristol.—In his report on the recent fatality at one of the transformer stations of the Bristol Corporation, Major Cardew recommends the enclosure of the high-pressure teminals and fuses in the transformer casing, and that the position of the high-pressure fuses on the switchboard at the generating station should be altered.

Electric Traction in Italy.—It is stated that Messrs. Tedeschi and Co. have placed a site at the disposal of the promoters of the Diatto system of electric traction with underground conductors for the purpose of demonstrating the method. It is also reported that Mr. Diatto has obtained for 10 years a concession for the working of his system on one of the Turin tram lines.

China and Burma Telegraph.—The Secretary of State for India has received a telegram from the Viceroy, stating that the junction of the Chinese and Burmese telegraph lines was effected on March 16, a month and a half earlier than the latest date fixed. This result was due to successful efforts made by the Telegraph Department to effect the connection as quickly as possible, and to the promptitude with which Chinese officers responded to those efforts.

Electrical Installations in Switzerland. — A paper dealing with an investigation of various electrical installations in Switzerland and Savoy has been contributed by M. A. Lavezzari to the *Proceedings* of the French Society of Civil Engineers. The paper, which is of a historical nature, describes the systems carried out for utilising the motive power of the Rhone at Geneva, the Salève electric railway, the Orbe tramway, the station of the Vevey-Montreux Company, and the Vevey-Chillon tramway.

The Government and Telephony.—In the House of Commons, on Monday, Mr. A. Morton asked the Chancellor of the Exchequer whether the nature of the proposals contained in the agreements with the telephone companies and the effect of those proposals would be placed before the Select Committee on Telephone Service. In reply, the Chancellor of the Exchequer said that he understood the agreements in question were already before the committee, and had been discussed by the witnesses.

Search-Lights for the Channel.—The Guildhall Battery site and buildings, for many years occupied by the headquarter staff of the South-Eastern District at Dover, are shortly to be vacated, and the staff offices removed to more convenient quarters. It is proposed to utilise the site for an electric light station to enable the Channel to be under the observation of search-lights from this point. There is no other point on the coast so favourable as Dover for observing the Channel, owing to the altitude of the cliffs.

Electric Cranes.—Some experiments were recently conducted at Havre with a new electric crane installed at the end of the Vauban basin on the Colbert Quay. The

Digitized by Google

current, which is supplied by the Société l'Energie Electrique, is taken from the generators which furnish current for the working of the tramways. The motor, which actuates the mechanism of the crane direct without the interposition of gearing, runs at from 200 to 300 revolutions a minute. It was made by MM. Hillairet and Huguet, of Paris.

Protection of Overhead Wires.—Mr. Karl Moritz describes, with the aid of illustrations, in the *Elektrotechnische Zeitschrift* of March 21, an arrangement for the prevention of accidents in case of the breakage of a bare conductor carrying high-pressure current, or in the event of the wire becoming very slack so as to cause a short-circuit. The device consists in the use of insulators and auxiliary crossed wires. The system has been tested with success in the central station of the Hungarian Electricity Company at Budapest.

Personal.—Mr. Walter Dixon, of 164, St. Vincent-street, Glasgow, has been elected a member of the Institution of Engineers and Shipbuilders in Scotland.—Mr. T. A. Nunwick, formerly branch manager and representative in the North for Messrs. Poole and White, Limited, has now joined the firm of Messrs. Dorman and Smith, Salford, as their representative for the Northern and Midland counties.—Mr. Fred. Bathurst, A.I.E.E., has joined the General Electric Company for the development of the internal conduit system of wiring.

Coupling for Electrically-Lighted Trains.—Mr. J. B. Brunn, engineering inspector of the Danish State railways in Copenhagen, and Mr. Busse, have devised a new form of coupling for connecting together the conductors between each carriage in electrically-lighted trains. The coupling is intended to overcome the difficulty experienced with other couplings when the trains are passing round curves. A description of the coupling, with illustrations apparently taken from a patent specification, is given in the *Elektrotechnische Zeitschrift* of March 14.

Post Office Telegraphs.—In examining the parliamentary return of revenue and expenditure relating to the Post Office telegraphs, one cannot but notice the increasing proportion which the percentage of total expenditure bears to the amount of revenue. In the year 1870-71 this is given as 59·57 per cent., in 1875-76 as 85·96 per cent., in 1880-81 as 80·08 per cent., in 1885-86 as 102·52 per cent., in 1890-91 as 97·22 per cent., and for the year 1894-95 it is estimated at the figure of 109 per cent. The total estimated revenue for this last year is £2,665,000, as against an estimated expenditure of £2,905,025—showing a loss to this Department of £240,000.

Rating of Machinery.—Mr. Shaw-Lefevre received on Tuesday evening at the House of Commons a deputation representing the Property Owners' Association of Great Britain, who objected to the Bill exempting machinery from rating, on the ground that in some towns it would increase the general rating 4d. in the pound. Mr. Shaw-Lefevre, in reply, said they had come late, as the Bill had passed through committee. In giving the measure a general support, he had only followed the example of Mr. Fowler and Mr. Ritchie. He advised the deputation, instead of trying to destroy the Bill, to get an amendment passed exempting certain towns from its operations.

Water Power in Scotland.—In the House of Commons a few days ago, Mr. A. C. Morton asked the Secretary for Scotland whether the County Council and the Roads Board had yet come to any decision as to the interference with the Falls of Foyers. In reply, Sir G. Trevelyan said that he was informed by the county clerk of Inverness-shire that the Foyers Roads Board at a meeting on the 8th of this month had postponed the consideration of the proposal to submerge certain roads till the May meeting, meantime calling on the Aluminium Company to submit to the Board the plans and sections of the proposed works, in order to enable them to judge whether the district would be injuriously affected thereby.

Transmission of Power in Switzerland.—An article was published in *L'Industrie Electrique* of February 25, dealing with a scheme for the electrical transmission of 3,200 h.p. a distance of 15 miles. The project concerns the utilisation of the water power of the Reuse, several concessions for which were granted some years ago. The power was to be distributed between Le Locle and Chaux-de-Fonds. A competition was opened and several schemes were received, but these were rejected and new proposals invited. The jury appointed to consider the projects have now decided in favour of the adoption of the direct-current system. The scheme adopted consists in the transmission of electrical energy at a pressure up to 14,400 volts, the generators being connected in series.

Decentralisation of Work.—In contradistinction to the general tendency to centralise industrial operations, the Compagnie Minière, of Blanzy, are making an experiment in decentralisation. The company have a workshop at Montceau where the miners' daughters are taught, free of expense, how to weave and embroider. One of the principals of the company, M. de Gournay, has hit upon the idea of finding employment at home for these girls when grown up and married so that they may not neglect their homes. For this purpose he has arranged for the electrical transmission of power from the Saint-Amédée mine to Montceau, a distance of 4·3 miles. The cables are brought through the mining village of Magny, and leads will be taken into the houses for the operation of the looms. It is stated that this is the first experiment of this kind made in France.

Lighting in Calcutta.—The question as to when Calcutta is to have a regular supply of electricity for lighting and other purposes has been often asked and as often answered by the echo, "When?" But there does appear, *Indian Engineering* states, to be some prospect of the legislation deemed necessary in the matter being brought to an issue before the present year is out. It will be recollected that an Electric Lighting Bill was drafted last year to meet the requirements of the province of Bengal, and that this has been before the Imperial Government. It is some satisfaction to learn that the draft Bill has passed under the anvil, and, having assumed a final shape, will now come back to be considered and adopted by the local legislature. The want of the electric light, our contemporary concludes, is felt in many public, as well as private, buildings.

Electric Tramway Between Niagara Falls and Buffalo.—Everybody in Niagara Falls is rejoicing, says a Buffalo paper, over the letting of the contract for the building of the electric road between the Falls and Buffalo. The contract was signed recently in Buffalo. According to plans, the line is to be built of 94lb. steel girder rails, with side trolley poles. It is to be double-tracked except for a distance of 2½ miles, where the highway commissioners of the town of Wheatfield refused to grant more than a single-track line franchise. The best feature of all is that it will give Buffalo and Niagara Falls cheap fares, the rate to be but 2s. for the round trip at all times. The running of late cars will keep hundreds of Buffalo people in Niagara Falls until late in the evening, who now are obliged to go home before the really enjoyable part of the day about the

Digitized by Google

Falls comes. The power for operating the line will be furnished by the Niagara Falls Power Company, and according to the contract the cars will be running by July 4.

London Telephone Service.—In a report presented by the Highways Committee of the London County Council on Tuesday reference was made to a previous report stating that, after careful examination of the proposed agreement between the Post Office authorities and the National Telephone Company, the committee were of opinion that the interests of the people of London would be prejudiced by the power to be given under the agreement to the company, whose existing monopoly would be further strengthened. A Select Committee on Telephony having been appointed, the Highways Committee have asked the deputy-chairman and the engineer to give evidence before it. The committee, moreover, think it advisable that one or more of the experts who advised them previously to the interview between the Postmaster-General and a deputation from the Council on February 4 last, should also give evidence before the Select Committee on behalf of the Council. The Council authorised the expenditure of a sum not exceeding £100 in connection with the matter.

Telegraphy and Telephony to France.—A Paris correspondent states that the telegraphic and telephonic cables between London and Paris have within the last month been so blocked with messages as to considerably interfere with the business which is carried on daily between the two capitals. At both the Bourse and the Bourse de Commerce in Paris there is a good deal of dissatisfaction with the existing arrangements, and representations are to be made to the French Minister of Posts and Telegraphs with a view to increasing the means of communication. The correspondent says that a telegram from London to Paris sent during the day often takes from one to three hours to reach its destination, while those anxious to use the telephone are obliged to take a turn which may reach them in two or three hours after the communication has been asked for. Under these circumstances, business in several branches of trade has become almost impossible between Paris and London. Stockbrokers and commercial men in Paris have very little faith, however, that any immediate result will be obtained by representations to the French authorities, and they hope that the attention which is thus drawn to the matter will induce those interested in London to urge upon the British authorities to take action.

The Chemical Society.—The anniversary meeting of the Chemical Society was held on Wednesday, Prof. H. E. Armstrong, the retiring president, being in the chair. The president, after mentioning that in giving up his office he severed 20 years' official connection with the society, referred to the Faraday lectureship and to the difficulty of finding men to hold it in view of the roll of distinguished persons on whom the honour had been bestowed. The discovery of argon was one of the most striking ever made in chemistry, and in recognition of the extreme value of his researches, as well as of his unwearied perseverance and consummate skill, the council had decided to ask Lord Rayleigh to be Faraday lecturer and to accept the Faraday medal. They did not ask him to deliver a lecture, but hoped he would give an address to the society on the subject of argon. In returning his thanks for the medal, Lord Rayleigh said that Prof. Ramsay stood on a footing of absolute equality with himself in regard to argon. The substance was isolated by Prof. Ramsay and himself independently, and he did not know who obtained it first. Prof. Ramsay then rose to make statement about argon. He had examined the gas (which according to an observation of Hildebrand's was nitrogen) given off by the mineral clevite when treated with sulphuric acid, and discovered that it contained argon. Spectroscopic examination showed a very bright yellow line nearly coincident with the yellow sodium line. This line was found to be identical in position with the yellow line observed in the spectrum of the sun's chromosphere, and attributed to the hypothetical element helium. Whether helium could be separated from argon remained to be seen.

Electrical Physics and Electro-Chemistry.—A lecture on this subject by Mr. Samuel Rideal, D.Sc. (London), was recently delivered at the Croydon County Polytechnic. The lecturer first considered the generation of electricity by chemical means. The uses and possibilities of secondary batteries were referred to, and then the chemical decomposition which takes place inside a cell was rendered evident by a number of experiments. The large production of chlorate of potash, of phosphorus, of aluminium, caustic soda and chlorine, etc., is now due in a great measure to electrical means, and examples of three processes were given. The aluminium furnace of Cowles and the electrolytic vessels used in other operations were shown by large scale diagrams and lantern projections on the screen. In addition to the practical uses of electricity in this direction, there are several scientific investigations in which it figures. Thus the Cavendish experiment to which is due the discovery of argon by Lord Rayleigh and Prof. Ramsay was repeated, and the production of ozone by means of the silent discharge was typical of the Andreoli and Fahrig systems already in commercial application. All such applications of electro-chemistry are either carried out in the neighbourhood of waterfalls, where a large amount of cheap power is available, or they may make use of the public supply of electricity to be found in all large centres of population. When electrolytic action takes place under circumstances where it is undesirable or unlooked for, then numerous troubles arise, such, for example, as the electrolytic corrosion of gas and water pipes, so prevalent in America, due to the very large leakage currents from electric railways, and in this country the explosions in conduits and culverts which have been so numerous lately. Experiments were arranged to illustrate these troubles and their probable causes, the lecturer submitting that they are probably due to true electrolytic action for the most part, and not merely to the alleged accumulations of coal gas in the underground passages and works. The appliances and plant used in the experiments form a part of the equipment provided for teaching purposes in the department of electrical engineering at the polytechnic.

Metric System of Weights and Measures.—The Public Control Committee of the County Council reported to the latter on Tuesday that the Weights and Measures Acts prohibit the use in trade of other than Imperial weights and measures. The system is little known or understood on the Continent, where the metric system of weights and measures is almost exclusively used. Export trade with foreign countries is therefore seriously hampered through having to be mainly carried on by the translation of Imperial weights and measures into their metric equivalents in accordance with a table appended to the Weights and Measures Act, 1878. In order to remedy a condition of things so injurious to the export trade of the country, and of London in particular, the London Chamber of Commerce has resolved to take early opportunity of bringing before Parliament, through its members and supporters in the House of Commons, a Bill to confer upon traders the liberty to use metric weights and measures for export trade purposes. The Council has been

Digitized by Google

asked to assist the Chamber to secure the passing of the Bill. The committee entirely agree with the amendment of the law now proposed, and they recommended the Council to do all in its power to secure the passing of the Bill for the amendment of the Weights and Measures Acts, so as to enable metric weights and measures to be used for export trade purposes. The Select Committee of the House of Commons on Weights and Measures met on Tuesday, when Mr. H. E. Woolmer, of Manchester, gave evidence. He gave it as his opinion that the difficulties in the way of a conversion to the metric system in this country would not be great. For instance, in Germany 3½ years' notice was given of the change which was about to be made, and it was found that at the end of two years even the working people were quite conversant with it. He spoke of the difficulties which Manchester merchants under the present system experienced in carrying on foreign trade. The necessity for a change of standard was more intense now than 30 years ago, because so many more countries had adopted the metric system, and also because of the increasing keenness of competition. Mr. A. J. Street, chief inspector of weights and measures for the City of London, gave evidence as to the present use of the metric system within the City and the difficulties which would probably attend its general adoption. In his opinion there were a great many wholesale houses and a number of bullion merchants who would welcome the metric system, but on the whole the retail traders were very much against it.

Electric Power for Canal Boats.—Experiments with the use of electric power in connection with canal boats are being made both in France and in the United States. According to the New York *Electrical Engineer*, the Lamb system is affording satisfaction. The results, our contemporary says, have demonstrated the system to be entirely feasible for canal-boat towing, and the Trenton Ironworks, of Trenton, N.J., who are introducing the system, stand ready to guarantee its successful working. The distinctive feature of Mr. Lamb's motor is that, unlike all others heretofore tried in telpherage systems, it is propelled by friction obtained independently of the weight of the apparatus. The motor can, in consequence, travel up the incline due to the sag in the cable net on approaching the brackets. The recent test was made to demonstrate the ability of the machine to tow a boat around sharp reverse curves. The deflection of the cable at each bracket was 6deg., and the motor pulled the boat at full speed around the right and left curves with ease. By this test it is proved that the motor can pull a boat around the sharpest curves to be met on any canal, as the tangents can be made as short as desired by placing the brackets close together, and a deflection of 6deg. be made at each bracket. On canals where the traffic is light a single cable can be used, and when boats going in opposite directions meet, they can exchange motors and proceed. This is done by exchanging hawsers. The low cost of the cableway makes but a light fixed charge for interest when two cableways are used. One of these cables would be erected on the inside of the tow-path, and the other on the berm of the cable on the opposite side. The mule traffic can, in consequence, be continued while the electric motors are in use. The system requires no changes in the present methods, as the electric motor simply takes the place of the mules. In this particular, this system has an advantage over all others, as the additional earning capacity of a boat due to the extra room thus gained is a very considerable item during the course of a year. Mr. Lamb claims that in comparison with electric propeller systems designed on the principle of the trolley all the disadvantages encountered in the recent State experiment on the Erie Canal are overcome by his system. These difficulties are, that the boat has to be steered so as to keep the trolley on the wire; the difficulty of two boats going the same way and the rear one passing the front one; on disconnecting the trolley, the boat loses its power and cannot proceed to get ahead of the boat in front of it. In the Lamb system they steer by each other and exchange motors and proceed.

The Protection of Electric Circuits.—Mr. W. E. Harrington read before the Cleveland meeting of the National Electric Light Association a paper on the "Correct Method of Protecting Electric Circuits.' He stated that the use of fuses for the protection of electric circuits has proved unreliable and unsatisfactory. The adoption of magnetic circuit breakers being, as it is, a foregone conclusion, led the author to make a study into the requirements entering into what would constitute a technically correct form of magnetic circuit breaker. The utilisation of the principle embodied in Helmholtz's formula gives the solution to the problem to determine the correct method of protecting electric circuits. The use of fuses for the protection of circuits has proved to be so antipodal to the fundamental principle contained in what is the severely technically correct method, that it is criminal, almost, in the light of present practice, for users to follow like sheep in the path of their predecessors in the use of fuses. The practical interpretation of the formula in question indicates clearly that if a circuit be opened during the rise or first surge in current upon a tendency for abnormal flow, and, further, if the time of opening be made as quickly as possible, the less the resulting flow of current will be. The hitherto standard form of magnetic circuit breaker, and the type familiar to all, is immeasurably preferable to fuses, in so far as it opens the circuit much quicker on the score of time. Fuses open the circuit so late after the heavy unusual condition of circuit is established that the current reaches the high and parallel part of current curves. A magnetic circuit breaker should be constructed to open the circuit in less and less time as the conditions become more and more severe. This can be done by taking advantage of the flux of lines of force due to the passage of the current, since, fortunately, the two are simultaneous; and by designing the magnetic circuit breaker to open as regards time in an inverse ratio to the increase of the lines of force, and not depending on springs or gravity, except, possibly, as auxiliaries to act as potential energy to aid in overcoming the inertia of the switch jaws and arms. We have then the correct method of protecting electric circuits. The destruction of electrical apparatus, the breaking down of insulation, the burning out of circuits, is taken by the business managers of electrical stations with a meekness and non-effort for relief which is astonishing. What business manager would permit his boilers to run with safety-valves of such a type that an increase of 500 to 1,000 per cent. of pressure would be required to open them? The author has repeatedly made tests showing that a No. 21 B. & S. gauge copper wire would permit the passage of 450 amperes for $\frac{3}{100}$ of a second without burning out or changing colour. In conclusion, the author stated that all switchboards and minor lighting circuits should be protected by automatic (as regards time element) magnetic circuit breakers, and the urgency of this will appeal to the exchequer of the management of the many electric light and power stations when the full meaning and import of Helmholtz's law dawns upon them.

THE THEORY OF ALTERNATING CURRENTS.

BY A.INST.E.E.

§ 1. **Introduction.**—Probably no branch of electrical engineering presents so many difficulties to students as that which deals with alternating currents, and as new terms and units, as well as relationships, not encountered in the study of continuous-current problems, are now every-day expressions, no apology is necessary for presenting this series of articles on the theory of alternating currents as an introduction to a more thorough study of this important branch of electrical science. As these articles are more particularly intended for that large class of young electrical engineers who have not had the opportunity of attending the courses of instruction at our technical colleges, we propose to introduce the various principles underlying the subject by briefly explaining the physical facts, so that the definitions of the units and terms in common use may be the better understood; and, although it is not to be expected that we can dispense with mathematics and mathematical language, yet it is hoped that the pains taken to simplify the mathematical relationships of the subject will enable the earnest student to master the fundamental principles of this important subject. As is well known, the study of alternating currents is a complicated one, simply because inductance and other factors affect such currents to a degree impossible with continuous currents, so much so that Ohm's law in its usual garb is not applicable to alternate-current circuits. These factors are so important that we shall tackle them singly, and shall first deal with the phenomena of self-induction and the practical unit of inductance—the henry.

§ 2. **Induced Currents and Self-Induction.**—Although it had been known for ages that a very close connection existed between the phenomena of electricity and those of magnetism, it was not until 1820, when Oersted, of Copenhagen, made the remarkable discovery that a current of electricity exerts magnetic influence in the surrounding space, and deflects a magnetic needle placed in the neighbourhood of the conductor through which a current is passing, that a satisfactory explanation was possible. Without doubt the announcement of Oersted marked the beginning of a new era in the history of physical research, the results of which were so startling, and the physicists of the time so stimulated, that in a wonderfully short time the foundation of the whole superstructure of electrical engineering was firmly established. Within two months of Oersted's discovery, Ampère gave to the world the results of his investigations in electromagnetism, and enunciated the laws respecting the dynamical action between linear conductors carrying currents. But the most brilliant achievement was that of Faraday, who, having explained the influence of a current or a magnet upon the surrounding medium, discovered in 1831 that a current is induced in an independent circuit placed near a magnet whenever the relative positions of the two change. This was the converse of Oersted's discovery, and, strange to say, the same discovery was independently made in America about the same time by Prof. Henry, who also has the honour of anticipating Faraday's later discovery by observing the phenomena of an induced current by an electric current in its own wire. The explanation of this, however, was reserved for Faraday, who two years later, traced it to its cause.

By considering what takes place when a current is sent through one of two closed circuits, P and S, shown in Fig. 1, placed in each other's vicinity, we shall get a clear insight into the cause of induced currents.

A steady uni-directed current established in P creates a magnetic flux of constant intensity and permanent position relative to P, and n lines of this flux thread through S, the value of n depending on the position of S relatively to P. The lines embraced by S will not vary so long as the current in P is constant, and no current will be induced in S until the relative positions of S and the lines from P change. An induced E.M.F., however, is at once set up in S immediately relative motion takes place between the lines of force and the coils of S, in consequence of which the value of n changes, and a momentary induced current flows round S in the direction indicated, which is opposite to the inducing current. Relative motion may be produced in several ways, the following of which are self-evident:

(1) By moving S or P.

(2) By stopping the current in P, since if there be no current in P there will be no lines in S; this is equivalent to withdrawing S.

(3) By varying the strength of the current in P; and

(4) By making the current in P intermittent, or by sending an alternating current through P.

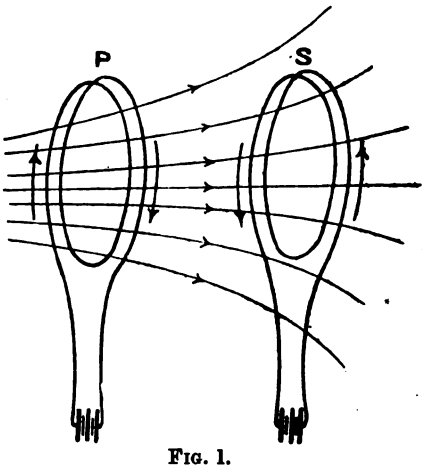

FIG. 1.

§ 3. If the current in P increases from zero to its full value, C, the flux passing through S increases from zero to n; and it must be noticed that if S contains m turns of wire, then each of the n lines cut, or is linked with the m wires—that is, we have $m\ n$ linkages—and if the current in P increases from zero to C units in one second, then $m\ n$ measures the E.M.F. induced in S during that second, and the pressure thus developed is termed the E.M.F. of *mutual induction*. Let $m\ n$, the product of the number of turns into the number of lines linked with them in one second whilst the current in P increases from zero to unity, be denoted by M, then the quantity M is treated as a constant, and is defined to be the *coefficient of mutual induction*, or the *mutual inductance* of P and S. It may be proved by experiment that unit current passing through S would produce M linkages in P under similar conditions; therefore the coefficient of mutual induction of two adjacent circuits is the quantity of magnetic induction passing through either of them produced by unit current starting in the other.

Since the flux in P is directly proportional to the current, it follows that when C units of current pass through P, that S encloses M C lines, and the E.M.F. induced in S during the setting up or collapsing of this current is M C units. As the number of lines threading S depends upon the relative positions of P and S, it is obvious that the maximum number is embraced by S when the two coils are co-axial, so that their centres coincide. It is also evident that since a current in a conductor acts inductively upon neighbouring circuits, it must also have a similar action upon itself whenever a change occurs in the strength of the current, and an induced E.M.F. is developed in its own wires, the direction of the induced E.M.F. being opposite to the E.M.F of supply. In other words, a back pressure is produced, the tendency of which is to obstruct the current in its own path. This back E.M.F. is greatest when the intensity of the flux within the coils changes from zero to a maximum, or from a maximum to zero—that is, when a circuit is made or broken. Thus, on closing a circuit of a voltaic cell, a definite fraction of time elapses before it establishes a current of constant strength, and during this time the E.M.F. of supply has to do work against the back pressure it is inducing. This was the discovery made by Henry, who termed such phenomena *self-induction*.

When such a current is broken the flux is gradually withdrawn from the coils, and this is equivalent to the flux linking the coils from the opposite side, and the E.M.F. is thus in the same direction as the E.M.F. of the cell. Naturally the current itself tends to continue in

Digitized by Google

motion, and in this it is assisted by the induced E.M.F., with the result that the pressure is so great that an exceedingly bright spark is produced. This property, in virtue of which a current "tends to go on" when the circuit is broken, is sometimes termed "electric inertia," and this idea is very useful in assisting us to remember that it is impossible to produce any instantaneous change in a current when self-induction is present in a circuit.

§ 4. As we have already inferred, the magnitude of self-induction, or *inductance*, as it is also called, present in a circuit in which the current strength varies depends upon the magnetic qualities of the circuit, which depend upon the current passing, the form and size of the coils and the presence of iron. And since alternating currents pulsate alternately in positive and negative directions at a rapid rate, it follows that the effects of self-induction are of considerable magnitude, and are almost as important as those of ohmic resistance—so much so, that it is necessary to be able to determine it quantitatively; hence a unit of inductance is required. In the absolute system of units we have an absolute unit of back E.M.F. when we have a change in the number of linkages, at the rate of one linkage per second, due to a change in the strength of the current at the rate of one absolute unit per second. If the change is L linkages per second due to change of unit current, we shall get L C linkages, when the current changes at the rate of C units per second. L is a constant, and is termed the *coefficient of self-induction*, which is defined as follows: the coefficient of inductance of a circuit is the quantity of induction passing through it per unit current in it.

The above unit, however, is too small for practical purposes, consequently 1,000,000,000 or 10^9 absolute units has been adopted as the practical unit, and is termed the *henry*. Thus, in practice, when the current increases uniformly from zero to one ampere in one second, and a back pressure of one volt is produced, the inductance of the circuit is one henry. The connection between the absolute unit and the practical unit of induction may be determined as follows:

$$\text{Back E.M.F.} = \text{inductance in henrys} \times \text{amperes},$$

or

$$E_s = L \times C;$$

where E_s is the self-induced E.M.F., L the number of henrys, and C the current in amperes.

Now, one volt $= 10^8$ absolute units of pressure,
and one ampere $= \frac{1}{10}$ absolute unit of current.

Therefore, if E_s and C are each unity, then

$$\text{one volt} = L \times \text{one ampere};$$

therefore, in absolute units, $10^8 = L \times \frac{1}{10}$, that is, $L = 10^9$ absolute units, as mentioned above.

In words, if a coil consists of one turn of exciting wire, then 10^9 lines of induction must cut it in one second so that we may have an inductance of one henry.

(To be continued.)

INSTITUTION OF ELECTRICAL ENGINEERS, Mar. 28.

At last night's meeting of the Institution the following paper was read:

On the Employment of the Electric Light for Railway Purposes.

BY W. LANGDON, MEMBER.

Having regard to the general character of the title of this paper, the author is desirous it should be understood that the data referred to are the result of experience gained on the Midland Railway. The Midland Railway was by no means the first railway company to employ the electric light for traffic purposes, and the author lays no claim to priority in this respect. On the contrary, he readily recognises the prior claims of others, and he earnestly trusts that his friends and *confrères* will feel no hesitation in bringing forward such information with respect to their own systems as may add to the value of the subject. It is well known that the Great Western Railway, the London and South-Western, the Brighton Company, the Lancashire and Yorkshire, the Caledonian, the Manchester, Sheffield, and Lincoln, as also the Glasgow and South-Western, have for some time, more or less, entered upon the employment of the electric light, and that the London and North-Western is now applying it to its goods depôts. The most material advance will, however, be found in the central stations recently established, in the one instance by the Great Northern Railway Company, under the guidance of Mr. W. H. Preece, C.B., F.R.S., past-president, at Holloway; and in the other instance that laid down for the Great Eastern Railway at Liverpool-street by our president, Mr. R. E. Crompton, C.E.

From all no doubt can exist that material information is to be obtained—information of value not only with regard to the question of economy, but also in the mode of application. In both the Holloway and Liverpool-street plants we have comprehensive schemes, the product of men of large experience and of the highest ability, from which results of an exceedingly gratifying character may well be anticipated. The electric light is employed on railways, as in towns, under its two forms—viz, incandescent and arc lighting.

Incandescent Lighting.

Incandescent lighting has so far found its chief employment in the illumination of offices, waiting-rooms, and other spaces of limited area. So employed, its claims upon our consideration are those which it has established in relation to our homes—a purer and more healthful light than can be procured from any other illuminant. In offices where a staff of workers are in constant attendance, or where, from the exigencies of the moment, work has to be carried on to a late hour of the night, it becomes to railway companies, as to all other employers of office labour, a factor of importance. To impute to the vitiated air breathed by those who occupy close rooms lighted by gas all the ills to which flesh is heir, would be absurd; still, so long as the air we breathe is robbed of its oxygen and otherwise polluted by the impurities cast into it by whatever may be the source of illumination employed, there can, in point of healthfulness, be no comparison between it and the electric light.

The argument against the electric light for the illumination of offices, waiting rooms, etc., is usually one of expense. With a small installation, or where the current has to be obtained from a supply company, the cost is at present, in most instances, probably greater than that of gas; but it is open to doubt whether such is really the case when we take into consideration the cleaning and redecorating of such places. We all know the effect of gas and the inconvenience of being turned upside down periodically for cleaning purposes. If we save by the electric light but one cleaning in three, it is probable that even the drawbacks of a small installation, or the present cost of current when obtained from an outside source, are fully met. If to these arguments we add that of health, we have a factor which carries with it far greater weight, and merits far more consideration at our hands. Health is money in more ways than one. It is money to the employer. It is more than money to the employed. It means to the employer more constant attendance, greater energy, and greater devotion to work on the part of the employé—gains alike to master and man. Whether the incandescent light may not yet prove of considerable service for the upper floors of goods warehouses, where light is only occasionally required, is an open question; and although in such places its advantages in a hygienic sense may be disregarded, it is, with a sufficiently large installation, quite within the realms of economy.

Wherever electric lighting is produced by a local generating plant every increase in the output of current tends to reduce cost. All such additions mean very little additional expenditure in production of current. The first cost is no doubt more than that for gas, but when we reach that point where the annual cost of the light produced is less than that of gas, such extra first cost is soon recovered. The directors of the Midland Railway Company have only recently installed the incandescent electric light throughout the offices, waiting-rooms, etc., of the Derby Station and headquarters offices. There is but one opinion of the result. The staff already feel the benefit of it in point of healthfulness and comfort, and the rooms and offices are practically as clean at the present moment as when the light was started. In the "shipping" offices—offices usually located on the platforms of goods-sheds, for the purpose of dealing with invoices, etc., and, as a consequence, necessitating very late, and sometimes all night, attendance—the advantage of the electric light is still more intensely felt, for in these offices an abundance of light is a necessity.

Arc Lighting.

There is reason to believe that arc lighting is destined to be of great advantage in railway working. In the loading and unloading of stock, and in the marshalling of trains, it is an invaluable adjunct. To be able to unload a train, load its contents into trolleys ready for delivery, and, *vice versâ*, to transfer from the collecting van to the railway trucks, marshal and despatch them with speed, is economy in capital, men, material, and time—results which are not confined to the depôt at which it originates, but which to a great extent influence the traffic of the entire system. The advantage of the arc light in goods

Digitized by Google

warehouses, yards, sidings, and marshalling grounds presides in the simple fact that it is a larger and truer light than can conveniently be obtained from gas for a similar outlay. By this larger light work is handled with greater accuracy and greater despatch. To be able to load a given number of trains in, say, three-fourths the time formerly occupied, is tantamount to increasing the capacity of the premises, warehouses, yard, etc., 25 per cent. ; or, supposing a depôt required enlarging in order to meet an increased traffic, the introduction of the electric light should meet the contingency, and avoid purchase of land, erection of additional buildings, etc. In like manner, with new buildings, economy in time means economy in capital outlay : the buildings need not be so large, because the traffic can be disposed of in less time.

Probably to no part of a railway system is the electric light of greater utility, or more valued, than in yard shunting, or the marshalling ground. With a brilliant light at the junction points the marshalling process may be carried on with almost the same despatch and certainty as during broad daylight. Risk of life and limb is largely reduced, whilst it has been found to be in no small degree useful in preventing that petty pilfering to which the absence of light is often an inducement. The author believes it to be a fact that the first arc lighting plant installed for yard working—viz., that at Nine Elms, which was devised by Mr. W. H. Preece, C.B., F.R.S., past-president, and installed by Mr. R. E. Crompton, our present president—was laid down mainly with a view to suppress certain depredations on valuable goods which the absence of light appeared to foster, and upon which its introduction has had so marked an effect as to help largely to defray the cost of the installation. Although, as already stated, by no means the first to employ the electric light, the Midland Railway was not long in recognising its advantages. In 1889 its adoption was recommended by Mr. G. H. Turner, the company's general manager, who at that time filled the post of goods manager, and who recognised in it one of those aids towards the rapid handling of material which at that time so largely occupied his attention in relation to the remodelling of many of the company's goods stations.

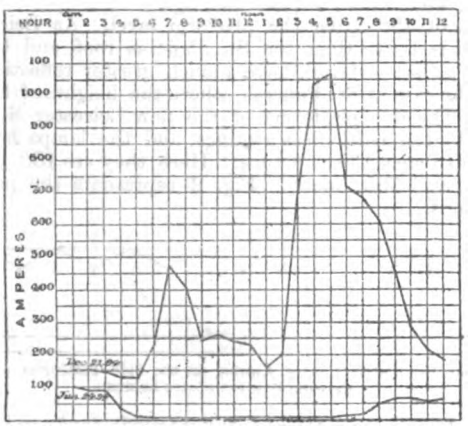

FIG 1.—Diagram of Maximum and Minimum Load at Derby.

In this remodelling of their chief goods depôts the directors have called to their aid all the most modern improvements, and amongst these that of the electric light. There is nothing of a purely novel character in the application of the electric light to these improvements, and the author feels that only in illustration of its general application and usefulness under aspects, perhaps, slightly varying from those which are associated with it in its use for public street-lighting, can this paper lay claim to consideration.

The first electric lighting plant laid down on the Midland was that established for lighting the St. Pancras Hotel. The generating plant established for this service is in duplicate, and consists of a simple non-compound horizontal steam-engine and two dynamos, each set being of 28-kilowatt capacity. The number of lights in the hotel is equal to 1,330 8-c.p. lamps at 110 volts, and the maximum load reached has been 320 amperes. The light load is met by accumulator cells, the dynamos being so arranged that one of the two driven by each engine can be employed for charging them, while the other is furnishing current direct to the lamp. The first arc lighting plant laid down was that experimentally installed by Messrs. Laing, Wharton, and Down, as representatives of the Thomson-Houston system, in 1888, at St. Pancras. The lighting was confined to the passenger station. In 1890 this plant was purchased by the Midland and extended to the St. Pancras goods station and yard. Insulated overhead wires—partly okonite, partly vulcanised—were employed. The installation has from time to time been largely extended, and now consists of 242 2,000-c.p. (nominal) arc lights, employed on the St. Pancras passenger station, the St. Pancras goods station and yard, the Somers Town (or New St. Pancras) goods warehouse and yard, sidings and approaches.

The engines employed for this installation consist of two pairs of simple horizontal non-compound steam-engines (coupled) served by locomotive boilers, three 50-light Thomson-Houston dynamos, being worked from countershafting driven by each pair of engines. This countershafting was originally arranged so that it might be coupled for cross-driving if needed, but up to the present no such need has presented itself. The engines were made and placed in position by Mr. Sam. Johnson, the company's locomotive engineer, and it is impossible to speak too highly of their performance. The electric lighting plant now in use or under construction on the Midland is approximately as represented in Table I. :

TABLE I.

Steam may be said to be employed throughout, with the exception of Leicester and Wellingborough. Leicester—which will be dealt with more in detail later on—and Wellingborough are dependent upon gas. A small gas-engine is also employed at Bradford and Birmingham (central) for the light load ; and, owing to want of space for extension of boilers at Bradford, we are now laying down two 40-h.p. gas-engines to meet an extension of arc lighting there. The boilers are in all cases of the locomotive type. The type of steam-engine varies. At Bradford some 200 h.p. of the engines are identical with those previously described as in use at St. Pancras. At Birmingham (central goods and Lawley-street goods), and at Sandon Dock, Liverpool, horizontal two-cylinder simple engines by Davey-Paxman are in use. At Leeds, two-cylinder simple by Fowler ; at Sheffield, single-cylinder steam jacketed by Marshall ; at Derby, Willans and Robinson single-acting compound ; all are non-condensing. The Willans and Robinson engines at Derby drive direct ; and, with the exception of St. Pancras and Bradford, where counter-shafting is employed, the driving is by belting direct from the engines. The engines employed for the arc lighting are generally 80 h.p., and are provided with two flywheels, each driving an arc dynamo.

At Leicester, with the object of testing the economy, or otherwise, of a gas-driven plant as against steam, a gas plant has been laid down. It has only recently been brought into use, and the installation is not even yet complete, the new passenger station being still in progress. A Dowson gas plant has been installed, and connection with the town gas has also been provided. The valves in the supply pipes are so constructed that either form of gas can be laid on to the engines without stoppage of the latter. The generating plant consists of four 50-h.p. gas-engines for driving three arc machines and one low-tension machine, and two of 25 h.p. for two small incandescent dynamos.

ARC LIGHTING SYSTEM.

Throughout the service the arc lighting employed in the yards and shunting grounds is on the series system. In certain of the goods sheds the series-parallel—two lights in series—system is used. Brush series machines are in use at Leicester, the Thomson-Houston at all other points.

INCANDESCENT SYSTEM.

The machines laid down for incandescent lighting are from various makers—Siemens, Edison, Hopkinson, Elwell-Parker, and Holmes. The incandescent lighting, with the exception of Derby, is on the simple parallel system. At Derby the three-wire system, with feeders, is in use. The blocks of buildings in this case are somewhat scattered, and the generating station itself is situated some distance away from the lighting. It is practically a small supply station, with, at present, a very bad load-factor (Fig. 1), much worse than that of a town supply station. Here, as also at Bradford, Sayers's automatic compensators are employed to counteract the fall of potential as the current increases.

The Midland Bradford Station, as is perhaps well known, is electrically lighted throughout, with the exception of a few gas lights under some low awnings at the distant ends of the platforms. Originally the incandescent lighting was provided for by compounded machines in duplicate. To change over from the working to the duplicate set involved careful handling on the part of the attendant. Discussing the matter with Mr. J. Sayers,

Digitized by Google

my assistant, under whose supervision Bradford came, it was decided to insert a series machine in one main and to dispense with the compounding. In the end this resulted in the employment of Sayers's "compensator," and which, I believe, was the first self-exciting machine made without winding on magnets. The application of this machine has been attended with the most perfect success. The transference of the load from the active to the duplicate set is now simply that from one shunt machine to another, while the compensation of the loss in pressure consequent upon the increase in current is most perfectly met.

At Bradford the wiring is on the simple parallel system. At Derby Dr. Hopkinson's three-wire system is in use. The success attending the employment of Sayers's compensators at Bradford naturally suggested their employment at Derby. At Bradford the extent of the compensation is limited to 11 volts, with a maximum current of 320 amperes. At Derby we have to serve a network, and the compensation is more involved, owing to the loss in the middle wire when either of the two sets of three separate groups of feeders is unevenly balanced. Dealing with one set, the arrangement is as follows: The outside wires of the grouped feeders are connected through a series machine driven by motor at a constant speed of 820 revolutions. This compensates for the loss in each outside wire. The loss in the middle wire is, of course, double-acting, raising the volts on the light-load side and depressing them on the other. To meet this, Mr. Sayers takes the middle wire round the magnets of each of the two series dynamos, but in opposite directions one to the other. Any current passing in this wire therefore adds volts to one, and decreases the volts in the other, equally; and by suitably proportioning this winding it can be made to practically neutralise the loss in the third wire. If both sides are fully loaded, and there is no loss, or no current passing in the middle wire, each series machine has to raise the voltage, on a current of 350 amperes in each, some seven volts; but as the third wire is one-half the section of the outer wires, it follows that if one side should be fully loaded and the other not loaded at all, the compensators have to give 7+14=21 volts, and this they should do under the arrangement provided.

Such an extreme case never has arisen in practice; still, serious differences do occur—more so, perhaps, in such a supply as that under reference than in a town service—for the reason that, however equally you may plot out your scheme, it is quite impossible to foresee all those contingencies which, calling for extra attendance on the part of a special branch of the service, call for the load on that side accordingly. A further advantage to be derived from the use of these compensators is to be found in the regular range of speed at which the engines require to be worked between light and full load. The volts of the main dynamos only require to be kept at the normal pressure—say, 110. There is no need for running the speed up so as to increase voltage to meet the drop consequent upon increase of current. It is one of those arrangements which simplify the working of a station at moments of pressure.

Installation.

The establishment of the various installations, with the exception of that originally laid down by Messrs. Laing, Wharton, and Down at St. Pancras, has been carried out by the company's own staff, under the immediate supervision of the author and his assistants, Mr. W. L. Preece and Mr. J. Sayers, and no small portion of the fittings required have been made in the company's electrical workshops. Arc lighting wires not employed for the interior of buildings are laid underground. When drawn into iron piping, the wire is not armoured, but is protected by an extra outer serving of flax, hemp, etc. When armoured wire is used it is protected by ordinary drain tiles, split, or by planks of wood, employed more with the object of indicating to those who may have occasion to disturb the ground in its neighbourhood the fact that there is something beneath it than with any idea of its power to absolutely resist injury. The insulation of the cable thus employed is specified at 5,000 megohms. Arc lighting wires inside buildings are insulated with vulcanised indiarubber to not less than 300 megohms, and are, as a rule, supported on Johnson and Phillips's oil insulators. All suspended lamps are also insulated from the suspension fixing by oil insulators made for the purpose by the same firm.

For goods-yard and siding working the selection of the positions for the lamp pillars, and the height the lamp should stand from the ground, are matters of importance. The former is only to be dealt with in a satisfactory manner by learning from those who have the handling of the work, and by personal observation where the light is most needed. Each group of points requires special consideration. Shunters should be able to see when wagons have passed over each point, so that they may readily "knock off" the next wagon or group of wagons as the required points are clear of the trucks previously despatched over them. At the mouth of the Leeds goods yard, where there are four roads, a light girder bridge has been thrown across, from which three lights are suspended between the roads, and the lighting is in consequence very good. The point is an important one, as from each line several fans of roads radiate, and it is beneath this bridge that the main part of the shunting is done. Without the girder bridge it would have been impossible to adequately light the intervening spaces between the roads.

Two classes of lamps are in use—that affording what is termed 1,200 c.p., and that known as 2,000 c.p. The former requiring a current of 6·8 amperes, and the latter 10 amperes, the 10-ampere lamp will afford a larger body of light than will the 6·8-ampere lamp. In station buildings, where structural arrangements do not intervene, the 10-ampere lamp illumines a larger space than that produced by the lesser current, and is, as a rule, arranged at a higher elevation, and further apart in consequence. In goods-yards and open spaces, theoretically, they should illuminate an equal extent of area. In point of fact, however, the illumination does not bear the same relation as when within enclosed spaces. Again, it may be said the 10-ampere lamp should be arranged at a higher elevation than the smaller lamp, but on the Midland it has been found convenient to employ only one class of pillar for outside work. The height adopted is 20ft.—*i.e.*, 20ft. between the arc and the level of the rails. The distance these pillars are apart varies for the 6·8-ampere lights from 90 to 100 and for the 10-ampere lights from 100 to 120 feet. The distance between the lamps in the goods sheds must, in a great measure, be controlled by structural arrangements, cranes, etc. In open sheds, where these difficulties do not exist, a distance of 45ft. between 6·8-ampere lamps and a distance of 60ft. between 10-ampere lamps will be found convenient. Every case will, however, call for special consideration and treatment. To lay down a rule which shall be universal and at the same time useful, is practically impossible.

The lights employed on the St. Pancras passenger station are 10-ampere. At the head of the station those lamps are 60ft. apart, the space between them increasing towards the end of the platforms, where the passenger traffic is not so heavy, the distance between the two most distant lamps being 90ft. The height of these lamps from the platform is 14ft. On the Leicester passenger station main platforms, where 10-ampere lights also are used, we are able to place the lights 90ft. apart, and at an elevation of 15ft. from the platform level. At Leicester the glass roof is lower than the St. Pancras roof, and the walls, being of glazed material, have a much greater reflecting power than is the case at St. Pancras, where the height of the lamps is 14ft. The side platforms of the new Leicester Station are covered by the usual glass awnings, and the lamps have to be arranged to meet the structure. Here they are 13ft. above the platform and 75ft. apart. Fig. 2 represents the position of these lamps.

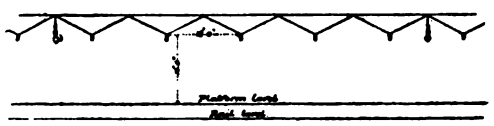

FIG. 2.—Longitudinal Section of Awning on the Side Platforms at Leicester showing Position of Arc Lamps.

In the Birmingham (Lawley-street) goods depôt and yard, the lights employed are of 6·8 amperes. Fig. 3 will probably afford a better idea of the disposition of the lights for such yards and buildings than will any written description. Within the warehouses, the cranes, with their radii, are lettered, while the pillars are coloured black. The Lawley-street depôt is still in an incomplete condition. A range of offices—now

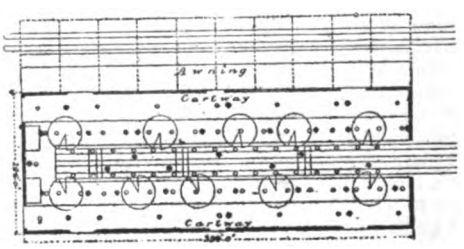

FIG. 3.—Plan showing Gas and Arc Lamps at the Central Goods Shed, Birmingham. Arc Lamps are indicated by an asterisk and Gas Lamps by a circle.

about to be constructed—will occupy the Lawley-street frontage, and the space between these offices and the main warehouse will be covered in by an awning. The lamps employed are double-carbon, jointly affording 16 hours' lighting; 13-mm. carbons are used for the 10-ampere lamps, and 12-mm. for the 6·8-ampere lamps, for both top and bottom carbons. In the earlier plants laid down the lamps are protected by sheet-iron hoods, A (Fig. 4). The lamp is suspended from a cross-piece of timber, B, by insulated hooks, or hangers, C, and it is further supported at its base by an insulator, D. Later constructions have been equipped with four-sided lanterns, Fig. 5. The top portion of the lamp is insulated from the lantern at A by a block of dry wood and insulated hooks, and

Digitized by Google

the base, as in Fig. 3, is supported on an insulator, B. These lanterns have been glazed (*a*) with plain clear glass, (*b*) with what is termed "blurred" glass, and (*c*) with fluted glass. The clear glass can be used only to a limited extent. The naked arc is objectionable to men working within its immediate range. Clear glass is perhaps still more objectionable, from the strong shadows which attend its use. "Blurred" glass has been employed with the object of toning down the glare of the arc and breaking up the shadows. It is, however, not in this respect so successful as the fluted glass. With the flutings horizontally arranged the shadows are completely broken up, and the refraction is so good that the light immediately underneath the pillar is practically as good as that 10ft. distant. The lanterns are made so that the chimney may lift off at A. All lamp-pillars are provided at their base with switches which entirely sever the connection of the lamp wires with the line wires, and in all modern constructions the switch, when in the "off" position, also places the lamp to earth. The lamp-pillar complete is shown in Fig. 6. The switch is enclosed in the base of the pillar.

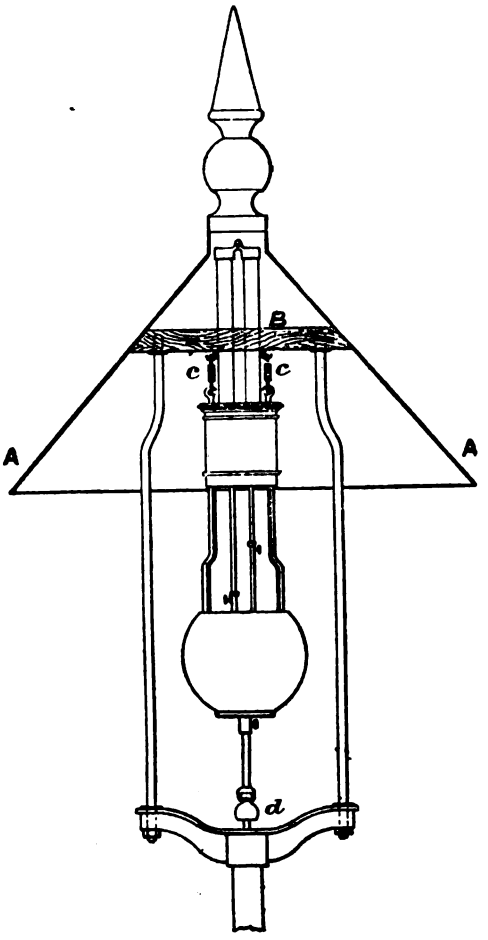

Fig. 4.

Where lamps are worked in series it will, in determining the circuit arrangements, be found desirable to ascertain the period during which the lights are required for use, and to group them accordingly, so that they may be turned off and on in sections, if possible, from the switchboard in the dynamo or transformer room. The groups should also be so arranged that, combined, they may equal the capacity of a machine. The circuits applicable to indoor lighting should be so arranged as to admit of their being worked independent of the outdoor or yard circuits, the light being required indoors at an earlier hour than those out of doors. For incandescent work the wires are, as a rule, run in grooved casing of the orthodox kind. The casing and cover are fixed by the outer and not by the centre fillet; the object in rejecting the centre screw being to exclude the aid it would afford to any creeping of the current across the centre fillet, should leakage at any time arise. Under such a condition it is clear the screw in the centre fillet would largely reduce the resistance between the two wires—that it would, in fact, become a sort of "half-way house" towards the passage of the current, and tend to ignite the wood. The wooden casing as at present employed affords a convenient mode of dealing with the wiring of rooms; but in view of the description of casing which one not unfrequently sees employed, and, indeed, under any circumstances, it can hardly be regarded as a perfectly satisfactory mode. If an artistic rectangular casing or tubing of metal which would not readily melt could be produced at a reasonable price, it would no doubt prove exceedingly serviceable.

Apart from the points referred to, there is, in the application of the electric light to railway working, little of a sufficiently special character to call for further reference. Numbers of the fittings employed, switches, switchboards, controlling arrangements, etc.—most of which are made in the company's own shops—are to be found in connection with each installation; but in this the installations on the Midland do not differ from all other installations, inasmuch as most have one or more specialities peculiar to themselves. Any such specialities are best investigated on the spot, and the Midland Railway Company will at all times be pleased to afford facilities for an inspection of any one of their works. The question which will probably most interest railway companies is that of

Cost.

To lay down an electric lighting plant is probably more costly than to establish means for illumination by gas; but when we take into consideration the relative cost of working, the light derived from each source—light for light, or candle-power for candle-power—the advantage is so largely in favour of the electric light as to more than fully compensate for any larger first outlay which may be incurred. The tabulated statement (II.) will afford data with respect to the output and cost of working of several of the electric lighting stations on the

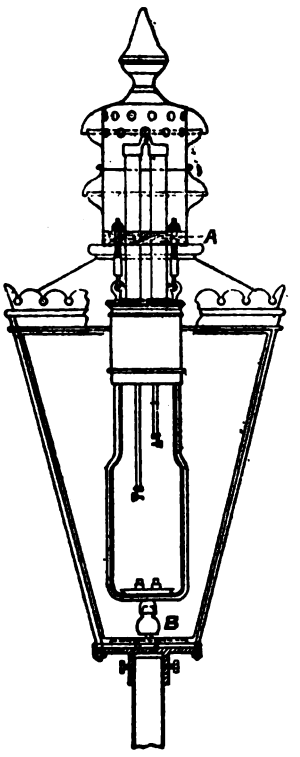

Fig. 5.

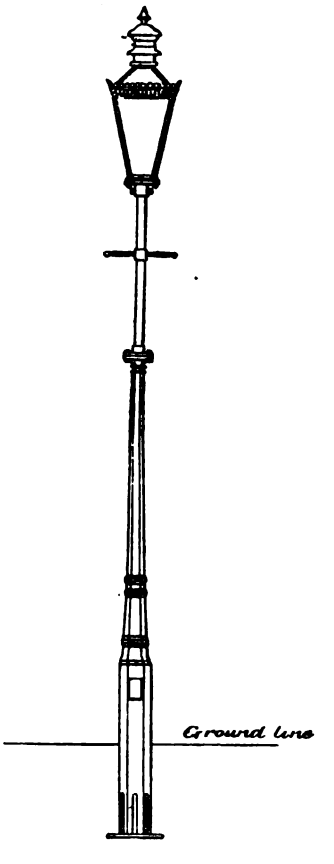

Fig. 6.

Midland. Certain charges for labour, engine and boiler repairs, and for coal, owing to charges for these items being combined with similar charges for hydraulic machinery located in the same building, it is possible, are not so strictly allocated as is desirable for a paper of this kind; still they are not largely inaccurate. They should, however, be regarded as maximum charges.

Nor are the charges in any case comparable with those of city supply stations. The arc lighting load, varying throughout the night according to traffic demands, is not so constant as that of a town service; while that for incandescent lighting lacks the continued evening service associated with town-lighting. At goods stations and for office lighting the latter rises to its maximum in the depth of winter for a period not exceeding an hour and a half daily—viz., 4 to 5.30 p.m.—while in summer the demand is still less. Still, the result, as compared with the cost of current obtained from a public supply source, is greatly in favour of an independent generating plant.

In criticising Table II.—viz., that of cost—we must also bear in mind the fact that the cost per unit carries with it the cost of carbons and carboning the arc lamps, together with cleaning, repairing, etc.; and that the cost for incandescent lighting also, as a rule, covers the renewal of lamps. The only exception rests with Bradford, where the lamps in the hotel are replaced by the hotel department, and their cost is not therefore included in the cost shown in the tabulated statement. Again, it should be understood that the appropriation of charges to incandescent and arc lighting, where both are in operation, is unavoidably somewhat

* These are 10-ampere lamps, 2,000 c.p. All others are 6·8 ampere, 1,200 c.p.

arbitrary. There are many items of cost which apply to both, such as labour in attendance upon the machinery, cleaning, etc. These have to be divided and appropriated as is considered fair and reasonable. The question will arise, is one favoured at the cost of the other? The result must speak for itself. Still one more condition! The output is obtained from records taken hourly, not from meter. The data are not, therefore, absolutely correct; but, taken over a period of 12 months, they are sufficiently reliable to afford a fair index of the cost.

Dealing with the table as it stands, we find the cost for arc lighting as under:

Depôt.	Cost per lamp per hour. d.
St. Pancras (Somers Town), 2,000-c.p. lamps	1·61
Birmingham (central goods), 2,000-c.p. lamps	1·41
,, (Lawley-street), 1,200-c.p. lamps	0·93
Leeds (Hunslet), 1,200-c.p. lamps	1·44
Bradford, 1,200-c.p. lamps	1·19
Total	6·58
Average	1·316

The lighting at Liverpool (Sandon Dock) and Sheffield has so recently been brought into use that returns from those depôts are purposely omitted. That at Wellingborough has only now started, and that at Nottingham is under construction. The daylight output for incandescent lighting at all of the arc lighting depôts is small. At Birmingham (central), where the lights are required in the bonding stores throughout the day, and at Bradford, where the demand applies to the hotel, station offices, and waiting-rooms, this is met by a gas-engine.

Some of the recently constructed goods depôts afford an opportunity for comparing the cost of the electric light with that of gas. Gas has been adopted as an alternative form of light in case of failure with the electric light. Consequently, the gas lighting was what might justly be regarded as modern gas lighting, affording an amount of light which, though not nearly so great as that afforded by the electric light, is greater than that which attained, and still attains, under the old system of gas lighting.

In the warehouses the gas lights are on the regenerative principle, and are each nominally 150 c.p.; the electric lights are arc lights, nominally of 2,000 c.p. It is officially stated that five cubic feet of gas, burnt under the principle referred to, will produce 25-c.p. light for one hour. There are 81 150-c.p. gas lights. The price of gas is 2s. 3d. per 1,000 cubic feet, less 5 per cent. On this basis, the cost of gas lighting would be 62d. per hour. There are 30 arc lights, the cost of which, as per Table II., averaged 1·41d. per light per hour. The total cost per hour would therefore be 42·3d., as against 62d. for gas, the relative nominal candle-power being—

Gas	12,300
Electric light	56,000

At Lawley-street, Birmingham, there are 53 arcs of 1,200 c.p., and, as an alternative, if required, 130 gas lights of 150 c.p. each. The arcs here average a cost of 0·93d. per lamp per hour. Gas is 2s. 3d. per 1,000 cubic feet, less 5 per cent. The result works out per hour—

53 arcs, affording 63,600 c.p.	49·29d.
130 gas, affording 19,500 c.p.	100·00d.

At Somers Town (New St. Pancras Goods) the gas used is manufactured at the company's own gasworks at Brent, near Welsh Harp, and is priced at 2s. per 1,000 cubic feet. The result is as follows:

29 arc lights, affording 58,000 c.p., cost per hour, 47d.
86 gas lights, affording 12,900 c.p., cost per hour, 61d.

If we extend these results so as to cover a period of a year—say, 3,000 hours—we have a saving of £1,050 per annum on the three ground floors of the goods warehouses referred to; and it is important to observe that whereas the charges for the electric light cover all charges—repairs, cleaning, etc.—the charge for gas is for gas pure and simple: there is no provision for cleaning or for repairs.

Gas Plant.

In the early portion of the paper reference has been made to a gas plant recently laid down at Leicester. This plant consists of four Crossley gas-engines, required to deliver under Dowson gas 40 h.p., and under coal gas 50 h.p., on the pulley of the dynamo, for the purpose of driving three 50-light 2,000-c.p. Brush series high-tension dynamos, and one low-tension dynamo employed chiefly for arc lighting; and two 14-h.p. nominal Crossley gas-engines required to transmit 25 h.p. to the pulleys of two Siemens incandescent machines. The service pipes are in duplicate—that is, one is in connection with the town gas, the other in connection with a Dowson gas plant. The engines are provided with valves which admit of the gas supply being changed over at will from coal gas to Dowson, or *vice versâ*. The object of this arrangement is to test the cost of gas as against that of steam. In construction, an ordinary gas plant saves the cost of boilers and chimney shaft and occupies less space, thereby effecting an economy in cost of building and cost of land. In maintenance there ought to be a saving in labour: no stoking is required when working off coal gas; and, as a rule, the attendance upon engines and dynamos is shared by the electrical attendants — engine-drivers and stokers are non-existent. Thus it would appear that there should, where coal gas only is used, be a saving of from two to three men. With a Dowson plant more space is occupied than if coal gas only is relied upon, and a man is also required for stoking and attendance upon generators. It remains to be seen if sufficient economy attaches to the employment of Dowson gas to compensate for the additional cost of plant, space, and buildings, and as regards maintenance, repairs, and labour.

The experience so far gained is scarcely sufficient to justify a definite expression of opinion, but the following test figures may be of some service. They should be accepted with reserve. The test extended over a period of four weeks during December, 1894, and it shows the following to be the cost of running, exclusive of repairs or renewals, but inclusive of carbons. Dowson gas was used during week-days, and coal gas on Sundays, or very occasionally:

Arc lights, 2,000 c.p.	1·2d. per lamp-hour.
Incandescent lights	2·3d. per unit.

It should be added that, although the output is not at its maximum—the whole of the proposed lighting not being yet established—the result here given is for a busy period. There will be periods during which the output will be much less, and consequently the result per lamp-hour not so good. As suggested, it is somewhat premature to attempt to draw a reliable comparison between this cost and that resulting from steam power; still, the figures are such as to inspire confidence in the experiment. At some future date the author will be glad to communicate the result of further experience.

Conclusion.

It is submitted that the experience so far gained establishes

Digitized by Google

beyond doubt advantages largely in favour of the electric light as an illuminant for dealing with railway work wherever a large body of light is required. At the same time, we must be sensible of the fact that daily experience teaches us to look for further developments in the machinery employed; and although this does not necessarily entail replacement of existing plant, it is as well to mark well that which it is desirable should be achieved. One improvement should be the abolition of belt driving. All driving should be direct from the shaft of the engine. The result will be less danger of interruption, less space, greater regularity. The speed of dynamo machines for arc lighting in series is now being brought within the compass of high-speed steam-engines. This accomplished, the propriety of direct driving for series, as well as series-parallel arc, commends itself to our consideration.

A further advance is to be looked for in the unification of the class of generator. At the present moment it is necessary, where series arc and incandescent lighting has to be provided, to lay down independent power and independent machines for each, or to drive the arc lights from alternating or transformed alternating currents. To drive arc lights on the series-parallel system for any material distance from the generating plant would entail so large an outlay in cable as to strongly militate against its adoption for such small plants as railway companies require. It would appear that what is needed is a generator the energy derived from which may be applied alike to incandescent lighting, arc lighting, or motive power—for the latter is an application which will have to be provided for. Is this to be most economically and most successfully met by an alternator or by a direct-current machine? Are we to look for help in this direction from "rectified" currents? If a system having for its basis one common generator can be established without too great a sacrifice in efficiency, small installations, such as would be of great service to railway companies in many busy centres, could then be brought within a more economical compass than is now the case. Three units—one for the light load, another for the full load, and a third of a similar capacity as spare—would probably meet the requirements of every depôt, whereas at present spare units for both arc and incandescent work are necessary.

For instance, at Birmingham (Lawley-street) the plant, when all is complete, will consist of six 50-light arc lighting machines and two incandescent machines. Now, if all this could be met by three generators—one for the light load, arcs, and incandescents combined, another for the full load, and a third as spare—the engine and dynamo space would be largely reduced, and labour and repairs correspondingly lessened. As opposed to this would be the cost of transformers and transforming-rooms. To help this we might possibly have reduced cost in cables, so that, regarded as a whole, provided that which is sought can be secured without too great a sacrifice in efficiency between the generative output and the production of light, or other means of consuming the energy, there would appear to be reason in regarding such an arrangement as highly favourable to economy.

Few, probably, will doubt that electrical energy is destined—and that at no distant date—to become a useful and economic agent at all important railway centres, not merely for lighting, but for traction and other purposes at present met by horse labour, hydraulic power, etc. In determining the ultimate design of generator and mode of working, this probable demand should be present to our minds, both with regard to the electrical system and the design of buildings for generating plant. That the demand for electrical energy will increase we may be sure, and our provision should in all cases be such as will admit of extension. Attached to this paper will be found copies of some rules and regulations in relation to restrictions, duties, and the management of electrical depôts such as are required for use on railways, which experience has dictated, and which may possibly be of service to others. Appended are also some precautionary instructions which have been issued for the avoidance and treatment of accidental shock from electrical current.

USEFUL RULES FOR THE GUIDANCE OF ATTENDANTS AND OTHERS ENGAGED IN ELECTRIC LIGHTING DUTIES.

1. It is important that everyone who has any duty to perform in connection with electric lighting machinery and apparatus should bear in mind that the lighting of those buildings, yards, etc., to which it is applied is dependent thereon, and that the apparatus employed for the purpose must, as far as is possible, at all times be ready for use.

2. The foreman of every installation, or, in his absence, the leading man, must on the approach of fog, or darkness from other cause, get the machinery into motion and the lighting in operation as soon as possible, after satisfying himself that the lamps on the circuits are ready for use.

3. Where the lighting of the station, buildings, etc., is entirely dependent upon the electrical machinery, steam must be in readiness for use at any moment.

4. All machines, wearing parts, belts, circuits, etc., are to be carefully tested and examined when shut down, so that any defect may be at once rectified.

5. One hour prior to the usual time for starting, the attendants in charge of engines and dynamos must carefully test and examine all parts of the machinery, circuits, etc., under their charge, and satisfy themselves that all is in good working trim and capable of carrying on the run for the time required. If any doubt should arise, the machinery must be started at once, in order that its condition may be practically tested.

6. Should anything transpire which may prevent the lighting, immediate notice must be given to all whom the absence of the light will affect, and particulars of the cause must be reported by telegraph to the divisional superintendent.

7. When necessary to change over from one set of machinery to another, or from one machine to another, every effort must be made to effect the change without interrupting the lighting more than is absolutely unavoidable.

8. The foreman in charge of the installation will be held responsible that a sufficient stock—not less than one month's supply—of oils, carbons, and all other necessary stores is kept on hand.

9. The inspector or foreman—or, in his absence, the senior man in charge—will be held responsible for the due and efficient performance of the duties of his staff. He is required to appoint the duties and rounds of the dynamo attendants, trimmers, cleaners, etc.; to see that those duties are faithfully and strictly carried out; that all parts of the apparatus are kept in perfect working order; to take every step in his power to ensure the successful working of the machinery and apparatus entrusted to his care; and to bring under the notice of his superior officer without delay any neglect of duty.

10. Smoking when on duty is strictly prohibited.

11. Attendants, trimmers, and others are required to sign on and off in the duty-book provided for that purpose.

12. Hot carbons when removed from a lamp are to be placed in a receptacle safe from fire. Any man throwing a hot carbon to the ground will render himself liable to instant dismissal. The ends of all burnt carbons must be collected and brought back to the engine-room.

13. Foremen and trimmers are to satisfy themselves that no possibility exists of burning particles falling from or passing out of the lamps.

14. Open lights are not to be used in goods sheds, depôts, or elsewhere, without special sanction from the senior officer of the installation.

15. All lamps employed in goods warehouses, sheds, or other covered spaces or rooms, are to be taken down and thoroughly overhauled at periods not exceeding six months in duration.

16. Whenever steps or ladders are required for use in public roadways, sidings, or lines of railway, every precaution in order so avoid accident by or to passing vehicles or foot passengers is to be adopted. If necessary, a man is to be posted at the foot of the steps or ladder to protect the man standing thereon, and warn approaching foot passengers or vehicles.

17. All men employed, whether trimmers or others, are required to take every precaution to avoid the possibility of accident to themselves or others. Anyone who may be called upon to deal with apparatus through which the electric current is at the time passing, or during such time as there may be a risk of the current prevailing, is to use sound indiarubber gloves.

18. Each trimmer on completing his section is to report the same personally, or by telephone where such is provided, to the engine-room.

19. No circuit is to be brought into operation for lighting or other purposes until it has been ascertained that the trimmers and all workmen are clear from it.

20. Workmen, when going off or coming on duty, are required to leave the premises by the route indicated by the officer in charge of the installation—and which is to be that route which will afford the most proper means of reaching the public street or roadway without crossing working lines of railway.

21. Disregard of instructions, neglect of duty, or incivility, will in all cases be severely dealt with.

Dynamo-Room.

22. The dynamo-room must always be clean, and everything in its place ready for use.

23. Immediately a machine is shut down it must be cleaned and prepared for further use in case required, and covered up till needed.

24. All machines, circuits, and part of apparatus must be tested when shut down, and an hour before being started. Where incandescent machines are kept running for several hours, the machine, as also the circuit, may be tested for earth during the run; but such tests are in all cases to be made through a "resistance" approved for the purpose by the superintendent, and as may be directed by him.

25. Where the frame of a high-potential machine is insulated from the bed-plate, daily tests are to be made in order to ascertain if there exists any leakage from the coils or other parts of the machine to the frame from which it is insulated. If such

Digitized by Google

is found to exist, those attending it are to be personally warned, and a notice in writing affixed to the machine cautioning all whom it may concern. The cause of the leakage should be traced and removed with all possible despatch.

26. Any difficulty which may present itself—loss of insulation of wires, or in the machine—is to be immediately reported to the superintendent.

27. Before starting, all binding screws and bolts should be examined. If a binding screw is loose, its surface should be examined. If found to be burnished, a fresh surface should be provided.

28. A diary and a duty-book are to be kept at each depôt. In the former is to be entered, by the chief attendant in charge, the condition of matters generally when leaving and when coming on duty, together with any circumstances which may have occurred during his duty, such as changes in the machines, irregularities of any description, details of the run, etc.

29. Iron and steel tools should be kept clear of all machines. Metal work must not be filed in their immediate neighbourhood. A copper oil-feeder with an insulated nozzle should be employed for lubrication. Oil or water must not be spilt upon or near any machine.

30. Any instructions which may be given by the superintendent with respect to the manipulation of switches, pressure of current, or changes to be effected, are to be most scrupulously observed.

Midland Railway.—Electrical Department.

Precautionary Instructions in Relation to the Avoidance of, and for the Treatment of Sufferers by, Accidental Shock from Electrical Current.

1. If ordinary precaution is observed in handling the electrical cables, wires, or apparatus, no danger need be apprehended; but where indifference to well-known restrictions, or negligence in any form, is allowed to prevail, serious consequences may ensue, not only to the individual guilty of such negligence, but to others who may be associated with him in the discharge of his duty. Regard any apparatus with which you may have to deal as capable of affording a shock, and adopt precautions accordingly.

2. No person should be entrusted with the performance of a duty until he is perfectly competent to deal with it.

3. When it is necessary for regulation or other purposes to touch parts of such apparatus when the current is active, the individual should be careful that his entire person is insulated from the earth, and from anything, other than an insulating medium, which connects with the earth. This may be best achieved by standing on an indiarubber mat. On no account should he touch parts of the machinery, cables, or apparatus with both hands at the same time, unless his hands are protected by sound indiarubber gloves. Shoes with indiarubber soles may be worn as an extra precaution, but the wearer must never rely upon them for insulation. Dynamo-room men should keep such shoes in the dynamo-room, and not wear them indiscriminately in and out of doors. The soles should be examined daily in order to ascertain that they are sound and dry.

4. The inspector and foreman of each depôt will be held individually responsible that a sufficient supply of indiarubber gloves are kept on hand to replace broken ones, and that one or more pairs (according to the magnitude and importance of the installation) are retained in a closet provided specially for he purpose (and marked I.R. Gloves), so as to be readily ccessible at any time.

5. Workmen are required, after using the gloves, to return them to the officer in charge of the dynamo or distribution room, and that officer will be held responsible that all gloves issued to workmen are returned to the closet or otherwise accounted for by an entry in the diary.

6. Should a lamp require attention during the time the current is flowing, the lamp is to be switched out of circuit before being touched by the switch at the base of the lamp-pillar, where such is provided; otherwise by the switch on the lamp, which, it must be borne in mind, does not insulate the lamp.

7. In cases of accident where a man has become paralysed by the current and is unable to extricate himself (*a*) the first effort should be to switch off the current; (*b*) failing the power to do this, to divert the current from the sufferer.

8. The first instruction is easily effected where the accident arises within ready reach of the dynamo, distributing-room, or switch.

9. The second instruction requires careful handling on the part of the rescuer. He has to bear in mind that if he touches the sufferer with his naked hands—even by his clothing, if damp from rain or the perspiration of the body—he may be placing himself in the same dangerous position as he whom he desires to rescue.

10. It is necessary he should keep himself insulated from the cable or apparatus, and from the sufferer, as well as from the earth.

11. Time is of the utmost importance, and will probably not admit of running for gloves or indiarubber mats. An instant of time may, if judiciously employed, suffice to release the sufferer, and any dry article of clothing may serve as an insulator for that short period.

12. If a piece of wire of sufficient capacity—an iron rod or any form of conductor—is at hand, the rescuer should, first, connect one end of the wire or rod to earth, and, failing a better means, divest himself of his jacket or coat and use it to insulate his hands from the other portion of the wire or bar and the cable whilst he attaches it to, or places it in contact with, the cable (or whatever may be the source from which the current is passing into the sufferer). The attachment should be as near to that part which is in contact with the sufferer as is possible. This may divert the current to the earth and release the sufferer.

13. Whether it does so or not the rescuer should, with continued caution, proceed to remove him from the position in which he is placed. He must insulate his own person by standing on a dry board, dry clothing, a bundle of dry straw, hay, etc. He must protect his hands by interposing as many thicknesses as possible of his dry clothing between them and the sufferer, and in this way endeavour to withdraw or raise and insulate the sufferer from contact with the earth. When insulated, the current will cease passing through him, and the cable, etc., may be withdrawn from contact with him. In doing so the rescuer must exercise great care that he does not place himself in a position to receive a shock.

14. Where a man is receiving a current through his person by having placed one part of his person in contact with one portion and another part in contact with another portion of a cable, etc., thereby forming of his person a portion of the circuit, the most ready means of delivering him is by short-circuiting such portion of the apparatus immediately outside the points of contact with the sufferer.

15. In cases where a man has received a serious shock, and life appears extinct, efforts similar to those employed in cases of drowning should be made to restore animation. Recent experience has shown that the system known as the "Laborde" system has been very successful. The treatment is as follows:

16. Lay the patient on his back in the open air. Remove his neckcloth and unfasten his collar. Open his mouth, and, taking hold of the front part of the tongue with your fingers—either bare or covered by a handkerchief—very slowly draw the tongue forward and as gently let it go back again 16 times a minute. Be sure that the root of the tongue is acted upon and drawn forward. Continue this action until signs of reanimation are observable, which should be the case in from 10 to 20 minutes. The motion thus imparted to the tongue should be regular and rhythmical in both its tractions and relaxations. If, in attempting to seize the tongue, it is found that the jaws are closed and the teeth clenched, open them by the finger, if possible, or, failing this, by a wedge-shaped piece of wood, the handle of a pocket-knife, or anything of the kind that may be at hand. Keep them wedged open.

17. The object of the traction effort on the tongue is to reinflate the lungs, and by that means reanimate the body. The rescuers' efforts should not be relaxed at the first appearance of reanimation. Those efforts must be continued until there is sufficient indication that this has been secured to such an extent as to ensure regular respiration by the patient without artificial aid. The patient should then be wrapped in such clothing as can be readily got together capable of affording warmth, and removed to the nearest hospital, infirmary, etc., or to his own residence if at hand, and placed in bed between blankets, with warm-water bottles to his feet. A little brandy may be administered as soon as the patient is able to swallow, the object now being by warmth to promote the circulation of the blood.

18. Another system is as follows: Lay the patient on his back in the open air. Remove his neckcloth and unfasten his shirt. Make a roll of clothing or anything else at hand and place it under his shoulders. The roll must be sufficiently large to so support the spine as to allow the head to fall downwards and backwards. The patient's mouth should be opened and the tongue drawn out to free the throat. The rescuer, kneeling behind the patient's head and facing him, should then grasp his elbows and draw them well over the head of the sufferer so as to bring them almost together above it, and there hold them for some two seconds. He should then carry them down to the sides and front of the chest, firmly compressing it by throwing his weight upon them. After some two seconds the action should be repeated, and continued at the rate of 16 times per minute. Under this action the extension of the arms expands the chest walls, as in inspiration or taking breath, and if the throat is clear the air will rush into the lungs. When the arms are brought down to the sides of the chest, compressing it, the air is expelled as in expiration. The action must be regular and rhythmical, and energetically and tirelessly persisted in until the breathing of the patient has again become normal. It is possible that this may not be assured in less than an hour.

19. If an assistant is at hand, both systems may be employed

Digitized by Google

at the same time, the tongue being drawn out as the arms are raised and allowed to go back as the arms are depressed, the combined action being as nearly as possible perfectly uniform.

20. The first opportunity should be taken advantage of, by the services of anyone within call, to obtain the presence of a medical man, who should, upon his arrival, be requested to take charge of the further treatment of the patient, the purpose of the foregoing instructions being to enable such restorative measures to be adopted as may be possible pending the arrival of a qualified medical practitioner.

21. It is to be understood that, although there is to be no hesitation in shutting down any machinery the movement of which for the time being may endanger life, it is important that the machinery should, especially where it is employed for the lighting of railway stations, thoroughfares, buildings, etc., made use of by the public, be set in motion again as rapidly as possible. It must not be forgotten that the sudden withdrawal of light from a busy passenger or goods station, or from rooms, offices, etc., may be attended with the most serious consequences ; and for this reason no time must be lost, should occasion ever arise for suspending the light, in reinstating it.

Before the preceding paper was read, the minutes of the previous meeting were confirmed. **Mr. R. E. Crompton** (the president) then suggested that the balance-sheet, which had been circulated among the members, should be taken as read. He then formally moved the adoption of the balance-sheet.

Mr. Aylmer having seconded the motion,

Sir David Salomons (the hon. treasurer) drew attention to one or two interesting points in connection with the financial position of the Institution. In the first place, he had mentioned two years ago that the Institution had a surplus of £200 in the form of furniture, which, if it were sold, might or might not realise anything. At present, however, they had net receipts amounting to £3,424 as compared with an expenditure of £2,601, leaving a suplus in cash of £823. As regarded the surplus assets they were valued at £10,712 in 1894, as against £9,459 in the previous year, so that the Institution was growing wealthier every year. The total value of the journals, library, and furniture amounted to something under £2,000. The Institution had invested and in other forms the sum of £8,712, and he thought they might congratulate themselves upon that fact. He added that since the balance-sheet had been issued £1,100 had been invested.

The motion on being put to the meeting was unanimously adopted without comment.

The paper having been read,

Mr. R. E. Crompton stated that they would all agree that the paper was highly instructive, and that they were glad to have it as an addition to the *Proceedings*. Among the points which might very well be discussed were the questions of series *versus* parallel systems of arc lighting, the proper height of the arc lamps, and the arrangement of the light bridge for the carrying of the arc lamps. It was startling to find a railway engineer coming forward with such a statement of the respective costs ; electric light engineers would not have dared to have put forward the figures in such a straightforward way. Then, again, there were the questions of steam *versus* gas plant, and belt-driven as against direct-coupled plant. It was to be regretted that the author had not referred to the subject of the transmission of power.

Mr. Fletcher, jun., of the London and North-Western Railway, asked the author whether in the second table he had included any charges for depreciation and interest on capital, and was answered in the negative. Proceeding, the speaker referred to an installation at the Waterloo Goods Station, Liverpool. In that case gas engines were employed, the gas costing 3s. per thousand. The plant, which had been running since October, comprised three 55-h.p. gas engines, driving three 36-unit dynamos. The distribution was on the three-wire system, and separate arc and incandescent circuits were used. As the meters were read every quarter of an hour, as compared with hourly readings mentioned by the author, the speaker considered that the figures were accurate. During the week they produced from 2,000 to 2,500 units, and they were able to do that at a cost of 2·28d. per unit, including all station charges, carbons for arc lamps, and renewal of incandescent lamps. The labour per unit was ·49d., engine-room ·09d., carbon renewals ·1193d., and gas consumed 1·476d. per unit. The cost per unit for arc lighting was ·203, and for incandescents 1·8d.; the depreciation worked out at ·4d. per unit. They therefore produced the current for slightly over 2¼d. per unit, including all charges. In conclusion, he mentioned that the number of lamps in the installation was 720 incandescents and 36 double carbon arc lamps.

Dr. Du Riche Preller observed that the author had not arrived at any definite conclusion as regards the cost in cases where town gas, Dowson gas, or steam was used as the generating power. From his own experience the speaker said that if town gas could be obtained at 2s. 3d. per thousand it was preferable to Dowson gas, if only for the reason that the first cost of installing the gas plant was saved. Concerning the intervals at which arc lamps were placed apart and the height of the lamps from the rails, he asked whether the author had ever tried arc lamps arranged from from 30ft. to 40ft. high. Experience of similar installations on the Continent showed that the universal rule was to place the lamps from 50ft. to 60ft. high, the distance between the lamps being between 80ft. and 90ft. He had no hesitation in saying that the best system for incandescent lighting was the alternating-current method. The speaker then described the three-phase system in operation at Dresden, which he stated was exactly as the author had mentioned in his paper. The economy given by the author was confirmed by the installations at Metz and Strassburg, and a saving of as high as 60 per cent., as compared with gas, had been found, the reason being that the cost of gas was 5s. per thousand. The speaker then referred to the rules given at the close of the paper in regard to the treatment of persons who had received shocks. Those rules were similar to those recommended by M. D'Arsonval. In this connection the speaker cited one or two cases where those rules had been unsuccessful, and then jocularly referred to some experiments of the effects of the electric current upon mice, guinea pigs, etc.

At this point **Mr. W. H. Preece** calmly suggested that the guinea pigs were directors, and some seconds passed before his meaning dawned upon the meeting—with evident amusement.

The discussion was then adjourned until next Thursday, the 4th April.

The following is a list of the candidates balloted for :

Members.—Albert Gay, 3, Quadrant-road, Canonbury, N.; Frederick Spencer, Oxford House, The Pleck, Walsall; Jacob Stöttner, the Electrical Company, Limited, Charing Cross-road, W.C.

Associates —William Gay Clarke, Paddockhurst, Worth, Sussex ; William Corin, 182, Devonshire-road, Forest Hill, S.E.; Henry M. Darrah, Hollypoint, Heaton Mersey, near Manchester ; Captain Frederick Dennett Falshaw, the Central South American Telegraph Company's Steamship "Relay," Callao, Peru ; Harry Stacey Howard, Casilla, 120, Lima, Peru ; Hilton Johnson, Great Northern Railway, King's Cross, N.; Walter Sydney Sharwood, Earlsbrook House, Earlswood, Surrey ; Herbert Edward Soper, Municipal Offices, Cheltenham.

Students.—Edward George Brown, 25, Stamford-road, Fulham, S.W.; Anthony Clark MacWhirter, The Faraday Electrical Engineering Works, Govan, N.B. ; John Charles Melvin Matthews, "Wykeham," Church Walk, Thames Ditton ; Charles Vernon Morgan, 27, Leabourne-road, Stamford Hill, N. ; David Wright Niven, The Faraday Electrical Engineering Works, Govan, N.B.; Frank Berkeley Wily, "The Knowles," Newton Abbot.

SUPERVISION OF PARIS CENTRAL STATIONS.

A scheme has now been practically completed by M Tavernier, engineer-in-chief of the town of Paris for the lighting of the promenades and for concessions on the public ways, for considerably extending the system of inspection of electric lighting in that city. The control of electrical and compressed-air companies was entrusted to this department of inspection in 1893, but this control has hitherto only been exercised from the point of view of the payment made to the town out of the amounts received by the companies possessing concessions. It has had nothing to do with the conditions of installation of apparatus and laying of mains. These conditions, in fact, which are imposed upon contractors with a view to the prevention of accidents, are not uniform throughout Paris. Each sector, or district, is provided with its own regulations, so that the rules prevailing in one part are not applicable in another. As a French contemporary points out, contractors have an interest in the elaboration of a single set of regulations for the whole city, so that in case of accident the responsibility may be clearly determined. When these regulations are approved, the supervision of installations and the proof of departure therefrom will be entrusted to the Service du Contrôl Technique de l'Eclairage Electrique. The new regulations are to be submitted to the Town Council for consideration.

Electrical Legislation in India.—The Central Union of German Manufacturers have addressed to the Union of German Electrical Engineers a communication referring to the Bill promoted for the regulation of electric light installations in the Bengal province. This Bill, to which we have previously referred, is now being considered, the union state, from the point of view as to whether the legislation should be made to apply to the whole of India. In view of this fact, and as numerous applications for concessions are now being made, the union urge that German firms should endeavour to secure a share of the work likely to accrue through the development anticipated from the passing of the Bill. Important firms or agents in this branch, the union conclude, are unknown, and no results can therefore be expected through enquiries being addressed to the German Consulate in Calcutta.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

CODES.

Telegraphic codes have been born by the necessities of modern commerce. That, again, has undergone a revolution because of submarine cables, connecting all the great centres of trade of the world. The principal cable ring started and supports a technical paper to enlighten the public upon the truths of cable work; but by a freak on the funny side of nature this heavily-aided journal scarcely ever deigns to recognise the existence of cables, or the necessity of certain policies in cable management. Perhaps the ring has nothing to gain by publicity, or it may be that by the sad irony of fate the said journal is run by a staff to whom cable work is an unknown field. No doubt the staff is able to record a jaunt about the Mediterranean by the figure-head of the ring with his friends in a ship provided for the purpose by the company, but hardly to find a valid excuse for such proceedings. When, too, we come to the more recondite matter of a code or codes, the public is not enlightened as to the necessity of not allowing an indiscriminate selection of words. On the matter of codes, Mr. J. Henniker Heaton, M.P., whose constant criticism of the Post Office has led to so many improvements, according to the *Times* writes as follows to a Liverpool correspondent: "In the *Times* of the 16th inst. you will find the Postmaster-General's answer to a question of mine on this subject, his view being that our hands are tied by our connection with the Postal Union. This is only another proof of the recklessness with which the interests of British trade are signed away by our amateur diplomatists at the Post Office. The cables are in British hands; the bulk of the world's trade in which cabling is required is in British hands; yet British merchants are not consulted in the matter. It is well known that a code cannot be too extensive, since the larger the number of words the greater is the choice of expressions denoted by them. Accordingly, hitherto merchants have been allowed to take words from eight appointed languages, and many of them have been at enormous expense to prepare codes from these languages, embodying upwards of half a million words. Now the official vocabulary only includes between two hundred thousand and three hundred thousand words, so that the range of expression is greatly restricted, while the money spent on private codes is henceforth a great loss. I say nothing of the objections to the official list arising from the use of similar pairs of words, the want of an index, etc. My contention is that, if there is to be an official list, it should include all suitable words in the eight authorised languages, or that, in the alternative, private codes drawn from these languages should be admitted. Anything less would amount to a serious diminution of the utility of cables, and a corresponding injury to British trade. In my opinion, a deputation should wait on the Postmaster-General to remonstrate against the imposition of the official list; above all, for extra-European cablegrams."

We owe so much to Mr. Henniker Heaton that a little adverse criticism will do no harm, and a little

Digitized by Google

commendatory criticism of cable management in this connection may do some good. Briefly, history will tell us that when the first cables were laid there were no codes. It will be seen, also, that eight languages may be used in the codification. The cost of cabling was soon found to be a heavy item in expenditure, and business men naturally wanted to reduce this expense. They therefore made up codes in which one word of code language may, when interpreted into ordinary language, stand for a whole sentence. With code-books in the senders' and receivers' hands, interpretation is easy, and so code messages soon took the place of ordinary language messages. For secresy, many merchants and manufacturers compile their own codes, and having eight languages to choose from, the result is a formidable total of words. Telegraphic signs are limited, and the indications on the recording instruments often feeble, and therefore difficult to read. The signs for many words of widely different signification are very similar, and so words may easily be mistaken. Without making this article too long, we may say at once we believe that the managers of the cable companies, whose initiation of a limitation to words to be used as code words must be granted, had but one object, and that beneficial to their clients. They wished to cast out all words that might be mistaken—and a cable mistake is often a costly matter—so saving expense. There are words so out of the way and so little used in the ordinary written or spoken language of these eight languages, that they ought not to be used as code words. A telegraph clerk is not a walking universal perfectly accurate dictionary in eight languages, and he often has to make a shot at the word intended to be signalled. If that word is an ordinary one, the chances are in favour of the correctness of the clerk; if a practically unused word, he may be at fault. Taking the few things we have said into consideration, and considering that, after all elimination, the compilers of codes have a quarter of a million, more or less, words to choose from, ought they not to be satisfied? We again reiterate—we believe it can be proved up to the hilt—that the labour of the selection of words has been taken primarily and mainly for the benefit of users of cables, to save them expense and possible error. To allow compilers of codes to use any word in the eight languages is simply to court expense and mistakes, and this an official list ought to minimise.

REVIEWS.

Elementary Lessons in Electricity and Magnetism. By SILVANUS P. THOMPSON, D.Sc, B.A., F.R.S, etc. New edition. Price 4s. 6d. Macmillan and Co.

This book is the recognised text-book in the majority of our schools and colleges, and, if from no other point of view, would therefore merit careful attention. But there are several other reasons why we should not only examine, but express our views upon this book. In the first place, no better exponent of current theories than the author can be found; but we entirely disagree with his teaching in the earlier lessons of this book. In our estimation he shows a woeful lack of intelligence, due to, so it seems to us, an attempt to run with both hare and hounds. But even when we disagree with the talented author, we have to confess his great ability and success in placing his matter before the student. In this notice our remarks will be chiefly confined to an examination of seven lessons, forming one chapter, some 80 odd pages in a book of over 600. With certain exceptions, our approbation of the book after Chapter I. is as emphatic as is our opposition to this particular chapter. Prof. Thompson will certainly understand our position, and we have no doubt will sooner or later acknowledge the correctness of our views by modifying his own accordingly. This is a book for the young student, and our endeavour is to make it as unattackable as possible. The rejection of schoolmaster's science when the student comes to practical work has gone on long enough. Prof. Thompson has supplied a mass of matter that cannot be rejected. This we admire. His style we admire, hence our hope that in one connection our adverse criticisms may be taken as friendly. In this book, as in all others, the author writes of and admits fully the idea of a "magnetic" and a "conductive" circuit. The surprise to us is that all his lessons upon induction are not based upon the "inductive" circuit. In these lessons upon "induction" he shirks principles, and leaves his readers to flounder hopelessly in the muddle of incompleteness. The acceptance of the "magnetic" and "conductive" circuit allows us to foretell the result of experiments. The non-acceptance of the inductive circuit leaves the student completely in the dark as to what the result will be under given conditions. Further, it necessitates a purely empirical method of treatment—a description of a lot of experiments that have no earthly connection in the mind of the reader, and are only connected when someone tells him that the results are in accord with a law as simple and as universal as Ohm's law is for the conductive circuit. We say this part of the book is incomplete, it suffers from omissions, and is far below the author's usual method of exposition. Let us give an example. § 63, page 75, is as follows:

"**Seat of Charge.**—Benjamin Franklin discovered that the charges of the Leyden jar really reside on the surface of the glass and not on the metallic coatings. This he proved by means of a jar whose coatings could be removed, Fig. 46. The jar was charged and placed upon an insulating stand. The inner coating was then lifted out and the glass jar was then taken out of the outer coating. Neither coating was found to be electrified to any extent, but on again putting the jar together it was found to be highly charged. The charges had all the time remained upon the inner and outer surfaces of the glass dielectric."

If the student is convinced by this so-called proof, we mistake the character of studentship. As Mr. A. J. Balfour points out in his admirable book on "The Foundation of Belief," this is just a statement made on authority and accepted without examination. We doubt, indeed, if Prof. Thompson himself ever gave a second thought to it. A doctrine accepted by everybody of any consequence, therefore authoritative, and to be accepted. Just for the sake of doing it, with the aid of the courteous principal of Messrs. Elliott's, St. Martin's-lane, we, the other day (March 26), carried out the experiments to corroborate the theory, as we think they ought to be carried out and described. In our case, we had two similar Leyden jars—Franklin pattern. One of these was charged by means of a Wimshurst machine. The outer and inner conductors of the charged jar were placed in position around the second glass jar, and it was found that the combination was *uncharged*. The uncharged conductors of the second jar were placed around the glass that originally was in the charged combination, and it was then found that this combination was *charged*. Here we did not return the original conductors, so that they could play no part in the final combination, but used altogether fresh conductors. This experiment, we think, and not that described by Prof. Thompson, proves satisfactorily that the charges remain on the glass. In our case there is no appeal to faith in authority, and we confess to little liking for the continued howling of speakers and authors for students to "open their mouths and shut their eyes," and swallow all that the, for the most part, self-constituted authorities tell them. It is a disgrace to

Digitized by Google

the second-rank science of to-day that it follows so servilely in the footsteps of authority. Let us have a little more freedom and look into statements, forming an independent opinion—it may be correct, it may be incorrect—without being ostracised for so doing.

It is all very well to credit authorities with this, that, and the other result, but there is far too much of this kind of thing done by Prof. Thompson, both here and in others of his books, and the credit is too frequently given to men whom we do not consider at all superior to others whom he and similar writers never by chance deign to mention. Another objection to the earlier pages of the book is the loading with description of obsolete apparatus. What does the young beginner want to know about "Henley's semaphore" or "the torsion balance"? except the latter is to lead to "the law of inverse squares," a law which is immediately said to be "only true when applied to the case of bodies so small as compared with the distance between them that they are mere points"—that is, applies to nothing in practice. In this part of the book we hold the diagrams to be wrong and the teaching useless. The static field between any two conductors is modified by several conditions, but all coming within the ken of a law similar to that of "Ohm" for the conductive circuit. On page 23, Fig. 16, for example, the reasoning only applies when the two balls are in a position impossible to obtain while we are human creatures and restricted to living on this earth. If a sponge is never put into contact with water it remains dry, and we are not surprised at the result. We are not surprised at the result when it is put into water. Just the same, we maintain that as we explain conduction, etc., by reference to the circuit, we must explain induction similarly, and should as little expect signs of electrification upon a conductor (Fig. 17) not in the inductive circuit as we should water in the sponge that has always been kept away from that fluid. There is no earthly way, or any other, of foretelling the results of induction except by reference to a circuit, and all these little fiddle-faddling experiments can be more and completely explained by such reference, and the results of any such experiments can thus approximately be foretold. Take, again, experiment illustrated in Fig. 19, page 28, and fancy the poor little elementary student asking, Why? He asks for bread, and he doesn't even get the proverbial stone—he gets no answer at all, and so it is throughout these first lessons. The last sentence in paragraph 31, page 38, provokes the question, Why is the distribution not uniform? but the oracle remains mute. But enough, we take it that in this first chapter of eight lessons Prof. Thompson has done what he rebukes others in his preface for doing—that is, taken his information from previous authors. As for the latter, and by far the larger, part of the book, Prof. Thompson has kept himself well abreast with the modern progress on magnetic and electrical matters, and, as we have said, has the happy knack of putting his matter in an easily understandable manner. We are not going to discuss the details of these chapters: they are extended, rewritten, and rearranged where the progress of knowledge required. The immense value to the student of a book of this kind causes us to regret exceedingly that we have felt bound to animadvert so strongly on the first chapter. For the most modern, the most complete, and, on the whole, the most satisfactory book for younger students, this book of Prof. Thompson's stands easily first. Altogether there are 14 chapters, divided up into 56 lessons, with appendices, questions, and a good index, though in the latter case we always prefer page to paragraph numbering.

St. Saviour's Baths.—These new baths, which are to be opened on the first day of next month, are electrically lighted. The work has been carried out by Messrs. Strode and Co., who have installed a Siemens dynamo, giving 120 amperes at 125 volts when driven at 900 revolutions per minute by a Marshall engine. The dynamo is used to charge a battery of 55 Johnson and Phillips accumulators. These supply about 237 lamps, or rather supply the number that are required to be switched on out of this total.

NEW GALVANOMETER.*

The galvanometer illustrated in Fig. 1 has been brought out by Messrs. Richard Frères, of Paris, for the purpose of meeting the requirements of a small, portable, and strong instrument for use in small installations. It is only 3in. in diameter. The instrument comprises a fixed part formed by a coil, B (Fig. 2), through which passes the current to be measured, and a soft-iron armature, E, movable round an axis. The directing force is produced by a horseshoe magnet, A. The latter is firmly fixed upon a copper plate by means of three screws. Upon this plate

Fig. 1.

and between the poles of the magnet is mounted the core of the coil, the wire of which has ends which terminate at the terminals, D D^1, serving for the taking up of the current. The movable part placed in the centre of the coil is arranged on an axis pivoting upon agates; it carries a toothed sector, S, engaging with a pinion, P. It is upon the axis of this pinion that is fixed the indicating needle, which moves upon the divided scale. All the parts are equilibrated, so that the position of the needle does not in any way depend upon the position given to the instrument. The divided scale is fixed on the outer face of the plate. The result of

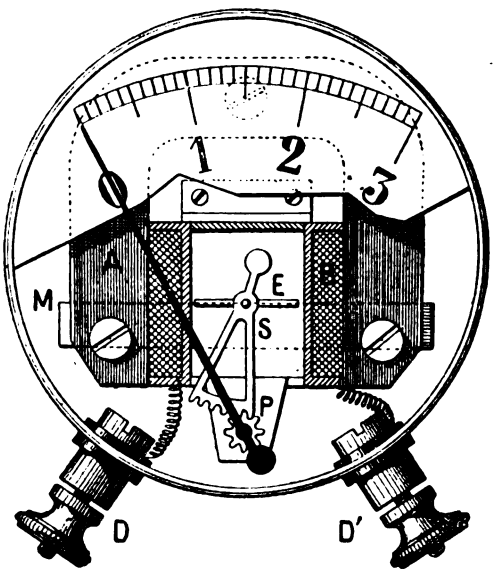

Fig. 2.

this is that it is only necessary to remove the bottom of the box by the withdrawal of three screws in order to see all the parts and ascertain whether everything is in order.

The working of the galvanometer is as follows: When the coil is traversed by a current it produces a magnetic field normal to that of the magnet; these two fields have a resultant which depends upon the intensity of the current, and according to which the movable part is directed. The angle of deviation is amplified by means of the toothed sector and the pinion, and we thus have a

* Abstracted from *L'Electricien*.

Digitized by Google

great movement of the needle for a slight displacement of the movable part. The mechanical amplification possesses the advantage of bringing about sensitively proportional deviations of the needle, since the armature, displacing itself but little, remains in a nearly constant magnetic field. One of the principal characteristics of this galvanometer is the use of an armoured magnet, the armature being formed by a bar of soft iron, M. This bar is kept in position by a brass sheet resting upon two pillars fixed upon the plate of the galvanometer. By this arrangement a very small portion of the magnetism of the magnet is utilised as the directing field, and having its circuit closed this magnet has no tendency to lose its magnetisation. The bar in question can serve for regulating, for according to its position the magnet is more or less shunted, and a more or less powerful directing couple is obtained, this allowing of the sensitiveness of the instrument to be modified.

It will be seen from this description that the instrument can either be used as a voltmeter or ammeter according to the thickness of the wire in the coil, B; but it is specially suitable for use as a voltmeter employed in connection with primary and secondary batteries. For this purpose, the two types made are of three volts and five volts respectively; the former has a resistance of 100 ohms, and can therefore serve to measure currents up to 30 milliamperes.

PRACTICAL NOTES ON DYNAMO CALCULATION.*

BY ALFRED E. WIENER.

(Continued from page 340).

In a very interesting paper entitled "On the Relation of the Air-Gap and the Shape of the Poles to the Performance of Dynamo-Electric Machinery," Prof. Harris J. Ryan has demonstrated the importance of making the pole-pieces of such shape that saturation at the pole corners cannot occur even at full load; for the armature ampere-turns cannot change the total magnetisation established by the field when the pole corners are unsaturated. He further proved by experiment that for a sparkless operation at all loads of a constant-current generator it is necessary that the air-gap be made of such a depth that the ampere-turns required to set up the magnetisation through the armature without current and for the production of the maximum E.M.F. of the machine shall be a little more than the ampere-turns of the armature when it furnishes its normal current. As long as the brushes were kept under the pole faces the non-sparking point was wherever the brushes were placed, no matter whether the armature core was saturated or not.

In order to enable currents to be taken from a machine at various voltages, W. B. Sayers has proposed to subdivide the pole faces by deep wide slots parallel to the armature shaft, Fig. 117, thus providing a number of neutral points on the commutator at which brushes may be placed without sparking. If, for instance, there are two such grooves in each pole-piece, the total voltage of the machine is divided into three equal parts, and by employing an intermediate brush at one of the additional neutral spaces, two circuits can be supplied by the machine—one each between the intermediate brush and one of the main brushes, one having two-thirds and the other one-third of the total voltage furnished by the dynamo.

45. *Base, Zinc Blocks, Pedestals, and Bearings—(a) Base.*—The base is the only part of the machine where weight is not only not objectionable but very beneficial, and it should therefore be a heavy iron casting, especially as the extra cost of plain cast iron is insignificant as compared with the entire cost of the machine. A heavy base brings the centre of gravity low, and consequently gives great stability and strength to the whole machine.

Besides this mechanical argument in favour of a massive casting, there is a magnetical reason which applies to all types in which the base constitutes a part of the magnetic circuit, as is the case in the inverted horseshoe type, Fig. 68, in the vertical single-magnet type, Fig. 73, in the inclined and vertical double-magnet types, Figs. 78 and 79, respectively, in the iron-clad types, Figs. 83, 85, 86, 87, 98, and 99, respectively, and in the vertical quadruple-magnet machine, Fig. 104. In these and similar types a heavy base of consequent high permeance reduces the reluctance of the entire magnetic circuit and effects a saving in exciting power which usually is sufficient to repay the extra expense involved, and often even reduces the total cost of the machine.

If the base forms a part of the magnetic circuit of the machine, constituting either the yoke or one of the pole-pieces, its least cross-section perpendicular to the flow of the magnetic lines should be dimensioned by the rules given for cast-iron magnets—that is, it should be at least one and two-third to two times the area of the magnet cores, if the latter are of wrought iron or cast steel, and at least of equal area if they are of the same material as the base—*i.e.*, of cast iron.

(b) Zinc Blocks.—In some forms of machines, such as the upright horseshoe type, Fig. 67, the horizontal single-magnet types, Figs. 71 and 72, the consequent-pole, horizontal double-magnet type, Fig. 78, the tangential multipolar type, Fig. 90, etc., the magnet frame rests upon two pole-pieces of opposite polarity; and if these were joined by the iron base the latter would constitute a stray path of very much lower reluctance than the useful path through air-gaps and armature, and the lines of force emanating from these two pole-pieces would thus be shunted away from the armature instead of forming a magnetic field for the conductors. In order to prevent such a short-circuiting of the magnetic lines, it is necessary either to use material different from iron for the base, or to interpose blocks of a non-magnetic substance between the pole-pieces and the bed-plate. The former method can be applied to small machines only, and in this case the magnet frame is mounted upon a base of either wood or brass. For large machines a wooden base would be too weak and too light and a brass one too expensive, and resort has to be taken to the second method of interposing a magnetic insulator, zinc being most usually employed. These zinc blocks must be of the necessary strength not only to carry the weight of the frame, but also to withstand the tremor of the machine, and must be made high enough to introduce a sufficient amount of reluctance into the path of leakage through the base. The reluctance required in that path must be at least four times, and preferably should be up to 10 or 12 times that of the air-gaps—that is, its relative permeance calculated from formula (114), chapter 38, according to the size of the machine, should range between one-fourth and one-twelfth of the relative permeance of the air-gaps as found from formula (126) or (127), chapter 39, the amount of leakage through the iron base being thereby limited to 25 per cent. of the useful flux in small dynamos, and to 8 per cent. in the largest machines.

This condition is fulfilled if the height of the zinc blocks, according to the kind and the size of the machine, is from three to fifteen times greater than the radial length of the gap space. The following tables, LIV., LV., and LVI.,

24	9¾	8	7
27	11	9	8
30	—	10	8¾
36	—	11½	9½

give the value of this ratio, the consequent height of the zinc blocks, and the corresponding approximate leakage through the base for high-speed dynamos with smooth-core drum armatures, for high-speed dynamos with smooth-core ring armatures, and for slow-speed machines with toothed and perforated armatures respectively:

From the comparison of the above Tables LIV., LV., and LVI., it follows that the height of the zinc blocks increases in a nearly direct proportion with the diameter of the armature core, and that for the same armature diameter a smooth-drum machine requires a higher and a toothed or perforated armature machine a lower zinc than a smooth-ring dynamo. By compiling the results of Tables LIV., LV., and LVI., the above Table LVII. is obtained, from which can be seen that the heights of zinc blocks for smooth-ring machines are from 18 to 30 per cent. less than for smooth-drum dynamos, and those for machines with toothed and perforated armatures are from 11 to 20 per cent. less than for smooth-ring armature dynamos.

(To be continued.)

A NEW METHOD OF MEASURING ILLUMINATION.*

BY EDWIN J. HOUSTON AND A. E. KENNELLY.

In almost all cases the object of artificial lighting is to provide a sufficient intensity of illumination upon the illumined surfaces. In practice, the illumination is generally required so as to permit some kind of work to be carried on. In any case, the character and intensity of the illumination will necessarily vary with the nature of the work. In a room in which reading only is to be done, it suffices if the proper illumination is obtained on the pages of the books—*i.e.*, on the reading tables, though the remainder of the room is comparatively dark. Where machinery is to be operated, the main light is generally required upon certain moving parts. In cases, however, where the character of the work requires the attendant to move about, or to observe some distant part of the machinery, a necessity exists for avoiding marked contrasts in the illumination of the room. Here it is clear that the use of a single source—such as an arc lamp—is undesirable, since, apart from the fact that it would produce a powerful illumination in its immediate neighbourhood, it would necessarily cause annoying shadows which could only be avoided by diffusing and scattering the light. It is evident, therefore, that in practice it is the illumination, rather than the luminous intensity of the sources, which is desired to be obtained and measured.

Although experience will enable the electrical engineer to determine the probable number and grouping of sources of light—such as incandescent lamps, which will be required to produce any desired illumination in any given space—yet it is well known that no rigid rule can be laid down as a safe guide in such cases, since the character and colour of the surfaces of the walls and ceilings will largely influence the illumination produced by a given arrangement of light sources. The question, therefore, as to whether or not a certain area is properly lighted cannot be decided so accurately from the number and grouping of luminous sources and their candle-power as it can from a method of actually measuring the quantity of light received per unit of area by a particular surface or surfaces whose illumination it is desired to know. In other words, the question at issue is not so much the photometric intensity of the sources of light and their distribution as it is the degree of illumination actually produced, and this question cannot be decided by the photometer, but requires the use of an illumination-measurer or illuminometer.

Suppose, for example, it is desired to illumine a billiard-room. Though experience must determine the number and position of the lamps, yet the commercial question as to whether or not the necessary illumination has been obtained upon the tables can best be determined, not by the number of separate lamps of a given candle-power, but by an actual measurement of the light received per unit of area on the table surfaces. In the same way, whether or not a certain grouping of lights over the tables is sufficient to illumine the rest of the room satisfactorily can be determined by the measurement of the illumination produced in different parts of the room. Similarly, in a dining or reading room it is the illumination of the tables that has to be specially provided for, and the question of proper lighting is best determined from a determination of the illumination of the tables, irrespective of the character or number of the lights present, except, of course, in so far as æsthetic requirements are concerned.

In street-lighting the requirements are that sufficient illumination be obtained on the surfaces of the streets, houses, vehicles, and persons, to be able to discern them clearly at reasonably sufficient distances. This primarily requires a certain intensity of illumination over a given area, and can best be determined from the actual measurement of the minimum illumination, rather than by calculations dependent upon a number of complex conditions, of which the photometrical intensity of the sources employed is but one.

Measuring the illumination rather than measuring the intensity of separate lamps would remove a source of great

* Paper read before the National Electric Light Association, Cleveland, February, 1895.

Digitized by Google

annoyance, both to electrical engineers and to municipalities, by rendering unnecessary discussions as to the candle-power of incandescent or arc lights employed, since, if the contract between the city and the lighting company be so drawn that the illumination in any part of a lighted street, for example, in the absence of moonlight, shall not be less than a certain minimum, all questions as to the candle-power of the separate sources will fail to affect the contract, and it only remains for the electrical engineer to provide such lamps as will, at the spacing employed, give the illumination contracted for.

So far as we know, there is no actual apparatus in existence, other than that we are about to describe, that will directly measure the intensity of the illumination at a given point, except the portable photometer of Prof. Weber, described by Mr. Heinrich at page 422, vol. xi., No. 7, July, 1894, of the *Proceedings* of the American Institute of Electrical Engineers. In Weber's photometer the illumination received upon a screen from a small standard amyl-acetate or benzine lamp is compared with the illumination to be measured. The difficulty of obtaining a reliable portable standard lamp, the rather cumbersome size of the apparatus, and the fact that it does not obviate the difficulty of comparing illuminations of different colours, have led us to devise a new instrument based on entirely different principles. We call our instrument an illuminometer, and have filed applications for a patent on the same.

A certain intensity of illumination is required to render a definite object viewed at a definite distance clearly delineated to the eye. It is well known that the illumination received upon a printed page of a book or newspaper must have a definite value in order to render the printed characters legible, and that the intensity of the illumination so required will, for a normal eye, depend upon the size and character of the print.

We employ this principle in the operation of our illuminometer as follows: A small test object of, say, printed characters, is placed in a darkened box, sufficiently small to be readily carried in the pocket. The test object is exposed to illumination received from a translucent plate of porcelain or opal glass, which receives directly on its surface the illumination whose intensity is to be measured. Since the test object receives the light from this plate by tranmission and subsequent diffusion, it is the area of the translucent plate exposed to the test object, in order to just render the latter legible to the eye, that determines the intensity of illumination upon the plate. A focusing eye-piece is placed opposite the test object for purposes of annulling the effect of any focal abnormalities of vision. A sliding shutter, movable by a milled headed screw, permits the effective area of the opal glass plate to be reduced until the amount of light received by the test object just permits of its legibility.

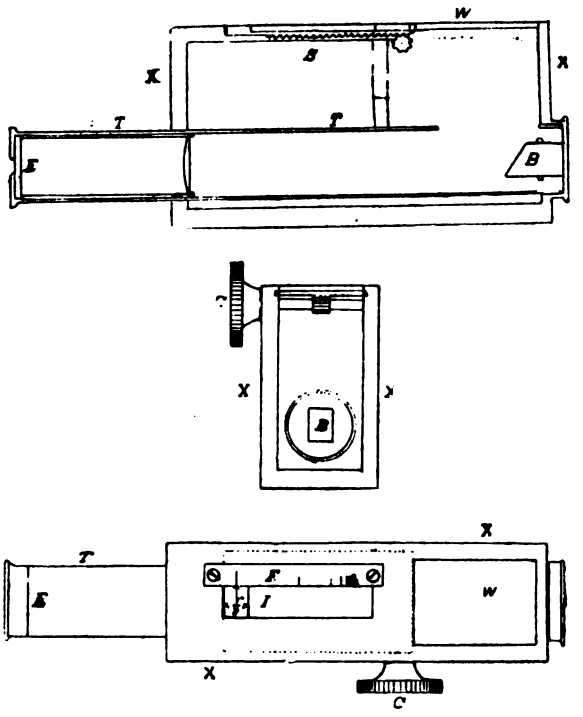
The detailed construction of our apparatus will be understood from an examination of Figs. 1, 2, and 3, which represent respectively a longitudinal cross-section, a transverse cross-section, and a plan view. A box, X X, blackened inside to prevent the reflection of light. is provided with a tube, T T, as shown. The test object is placed on a block at B, opposite the focussing eye-piece, E. At the top of the box is a window, W W, closed by a translucent diaphragm of porcelain, opal glass, or similar material. This diaphragm is placed so as to act as a secondary illuminator of the test object at B.

In order to regulate the amount of light which passes from the window, W W, to the test object, a sliding shutter, S S, operated from beneath by a milled headed screw, C, is placed in guides beneath the window, so as to cover any desired fraction of its surface. In order to determine the effective area of the window—*i.e.*, the uncovered portion which admits light to the test object, B, the index, I, attached to the shutter, moves over a calibrated scale, S, from which the amount of illumination on the window, W W, may be immediately read off in suitable units.

Calibration of the instrument is effected by exposing the window, W W, to known intensities of illumination in a photometer or darkened room, and marking off upon the scale, S, the points at which the indications of the instrument are obtained.

By the illumination on a surface is meant the quantity of light it receives per unit of area. Illumination may be expressed in terms of some unit illumination obtained from a definite source at a definite distance. Thus, a standard candle produces a definite illumination at the distance of a foot, and this illumination is sometimes called a candle foot. A less objectionable and more generally recognised unit is the illumination produced by an international standard candle at the distance of one metre and this unit is called the bougie-metre, or the lux.

The international standard candle above referred to is the *bougie decimal*, or the one-twentieth of the Violle, or molten platinum standard of light, adopted by the Paris International Electrical Congress of 1889. Authorities, unfortunately, differ as to the relative value of this decimal standard candle in terms of the British candle, or Sugg, which burns 0·1296 gramme per minute; but Everett in his C.G.S. system of units, 1891, gives data which make the international candle 0·988, or about 1·2 per cent. less than the standard British candle. Approximately, therefore, one lux is the illumination produced by a standard British candle at a distance of a metre.



FIGS. 1, 2, AND 3.

In employing our instrument for such a purpose, for example, as measuring the illumination upon the surface of a table illuminated by daylight, candle light, or incandescent light, we place the illuminometer upon the table with its window up, so that its window being only 2in. above the table practically coincides with the surface whose illumination is to be measured. The eye is then applied to the eye-piece and the test object focussed under the full illumination. The shutter is then gradually moved over the window until the test object just remains legible, when the number of luxes in the illumination of the table are shown by the index on the scale.

The degree of accuracy with which these measurements can be made, though small as compared with such determinations as length, mass, and time, nevertheless does not compare unfavourably with photometric measurements in general. It is well known that two observers may vary in their determinations of the candle-power of a incandescent lamp by 5 per cent, and, when the lights to be compared have different colours, the variation is often much greater.

The mean error of a single observation with our instrument is 10 per cent.—that is to say, if a number of measurements be successfully made of an illumination within the range of the instrument, the average deviation of any single measurement from the mean of all the measurements is, with the instrument here exhibited,

Digitized by Google

about 10 per cent., although we believe certain changes we have in view will notably reduce this percentage. Such tabulated observations are appended. In the instrument exhibited, the graduation of the scale extends from four luxes by single luxes to 15, then to 35 in divisions of five luxes, then to 70 in divisions of 10 luxes, while the highest reading is 400. The total length of the scale is 1·5in. The total length of the instrument is 5½in., its breadth is 1·5, and its height, excluding the milled headed screw, is 2¼in., so that the apparatus can readily be carried in the pocket. Its weight is 10oz.

It might be supposed that two different observers, having different limits of distinct vision, would obtain different results in determining a given illumination by the use of our instrument. In point of fact, however, we find that by the use of the focussing eye-piece, distinct vision of the test object being readily secured for each observer, the results of different observers do not appear to differ by more than the limits of probable error for the apparatus.

It is known that an illumination of five luxes is sufficient to permit the reading of ordinary print, although, on physiological grounds, the eyes should not be used for continuous reading at illumination less than 10 luxes. Fifteen to 25 luxes may be regarded as proper artificial illumination for reading.

(To be continued.)

NEW AIR-SPACE INSULATED CABLE.

The growing demand for underground telephone and telegraph cables and the increase in the price of guttapercha have induced cable-makers to seek new means of meeting the requirements with as good results as have hitherto obtained, and particularly in regard to securing a capacity as low as possible.

In this connection the *Elektrotechnische Zeitschrift* points out that Mr. Franz Clouth, of the Rheinische Gummiwaarenfabrik, Cologne-Nippes, has introduced a telegraph cable which, independent from the expensive guttapercha, has a very low capacity and yet retains the usual diameter and ratio of weight. With a copper resistance of six ohms per kilometre at 15deg. C., the capacity amounts on an average to ·052 microfarad per kilometre, and the insulation resistance 10,000 megohms and above. The cable consists of seven strands which are surrounded by a double lead covering; it is wire armoured for drawing into pipes. The strands are insulated by means of cotton arranged round the wires lattice fashion. A three-mile length of cable of this type has been laid in Cologne. After laying, the electrical conditions were:

No.	Insulation in megohms.	Capacity in microfarads.	Resistance in ohms.
1	8,268	·053	5·98
2	9,500	·054	6·12
3	9,500	·053	6·22
4	9,570	·054	6·56
5	9,570	·054	6·28
6	9,850	·054	6·28
7	19,140	·043	5·99

The figures are per kilometre at 15deg. C.

THE RECENT EXPLOSIONS ON SOUTHWARK BRIDGE.

MAJOR CARDEW'S REPORT.

We give below the report, bearing the date of February 7, of Major P. Cardew concerning the series of explosions which occurred on February 1 on Southwark Bridge.

I have the honour to report that, in accordance with your instructions, I held an enquiry on the 4th inst., as detailed above. The City Solicitor represented the Trustees of the Bridge House Estates, the department of the Corporation vested with the care and maintenance of Southwark Bridge. Mr. F. Bailey, chief engineer to the City of London Electric Lighting Company, and Mr. F. Livesey, chief engineer to the South Metropolitan Gas Company, attended each on behalf of his company.

I append a transcript of shorthand notes of the evidence taken, kindly furnished by the Corporation of the City of London. Also a plan and section, marked A, showing the various pipes and manholes, etc., at the spot where the explosions appear to have originated and a tracing marked B, giving a plan of the entire bridge, and showing the street boxes in connection with the mains of the electric lighting company in which explosions took place; this also indicates the pipes, manholes, etc., at the south end of the bridge. In order to explain the occurrence of these explosions it is necessary to refer in considerable detail to these underground arrangements, which consist of:

First, a brickwork culvert covered by an iron grating, and used in connection with the surface drainage, which crosses under the roadway, terminating on the east side in a "dead end" under the pavement, but on the west side an iron pipe connected to the culvert passes through the side of the bridge, and is continued down to the river. This is shown in plan and section marked A and in tracing B. At each side of the roadway catchpits have been recently constructed, discharging by means of a short length of pipe, not trapped in any way, into the culvert. These catchpits have the usual iron gully gratings at the level of the road. Under the footway on the west side there is a manhole closed by a stone slab and giving access to the culvert. A 3in. cast-iron gas-pipe crosses about 6in. above the culvert in the roadway on the west side, as shown in plan A. This pipe bends at right angles and terminates in a "dead end," but a small service pipe is taken from it to a gas meter in a pit under the footway. From this meter a supply is given to the lamps on the west side of the bridge by means of a pipe led along the outside of the parapet. The pipes belonging to the electric lighting company pass along under the footway just inside the kerb. They cross over the culvert and over the 3in. gas-pipe, but under the small gas-service pipe. None of the electric lighting company's pipes, however, at this spot contain mains, these being led away from the two street boxes shown in tracing B, on the west side of the bridge through the parapet, and down the pier of the bridge in a large iron casing. On the east side of the bridge there are a large number of electric mains in iron pipes and in bitumen casing passing under the footway and over the culvert.

From the evidence given at the enquiry there appears to be no doubt that the first explosion occurred in the culvert under the pavement and roadway on the west side of the south end of the bridge. Several witnesses were positive that this explosion occurred first by an appreciable interval of time, and one of them, Mr. W. C. Palmer, could hardly have made a mistake on this point, as he was in a pony-cart close to the explosion, and the pony and cart had moved across the road before the second explosion took place. This first explosion was by far the most intense of all which occurred, many paving stones being completely shattered. One woman was reported to be rather seriously injured by the *débris*. It was immediately followed by three explosions in the street boxes of the electric lighting company on the opposite (east) side of the bridge. These street boxes I have marked *b*, *c*, *d* on tracing B. One woman and two men were injured by these explosions, one man being blown up about 6ft or 7ft, according to the evidence of a policeman. This man, however, was able to give evidence at the enquiry. The covers and frames of the boxes were broken, and the pavement displaced at each box. A slight explosion appears also to have occurred in the street box on this side marked *a*, but this was not sufficiently intense to displace the cover. The officials of the electric lighting company were on the spot shortly after the occurrence, and those of the gas company as soon as they could be summoned. They found both the gas-meter boxes full of gas, which was also issuing freely from the gully grating over the catchpit on the west side.

On opening the ground over the culvert a large crack was found in the 3in. gas-main, out of which the gas was coming in volumes. This crack extended about half-way round the pipe, on the upper side. There was also a longitudinal crack in the pipe at the same place, but this appears to have been an old injury, and to have so far rusted up that there was little, if any, leakage through it. The roadway over this gas-pipe was frozen very hard, and was practically impermeable to gas, but between the pipe and the grating of the culvert immediately below it the soil was very loose, and some vacant space seems to have existed. Thus the gas found easy access to the culvert. How it was fired cannot, I fear, be exactly ascertained, but I think I can confidently assert that it was not by means of the electric lighting mains As before mentioned, there were no electric mains in the immediate vicinity of the first explosion, and the empty pipes prepared to take the mains do not appear to have been in any way injured. These pipes, it is true, communicate at a distance of about 16ft. with a street box which contains electric mains. I examined this box, but found no signs of any firing of gas having take place within it. The voltmeter records of the electric lighting company show no trace of disturbance on the circuits at the time of these explosions, and as the mains in use were all concentric cables, the outer conductors of which were thoroughly connected to earth at the generating station, I do not think they are likely to have produced a spark. The fact that there was no explosion in the street boxes on the west side of the bridge is a further proof that the escaped gas had not penetrated into them, and in consequence that it could not have been fired by the electric mains.

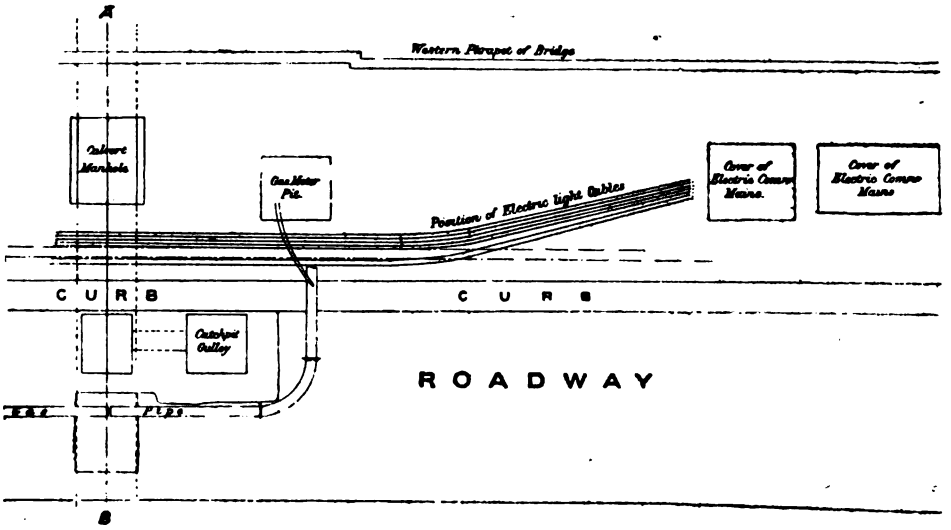
It was stated in evidence that a match which had recently been alight was found in the catchpit communicating with the culvert, and this may possibly have fired the gas. I believe that in the case of firing by ordinary flame it sometimes happens that the gas burns quietly for a considerable time should it be in too great

Digitized by Google

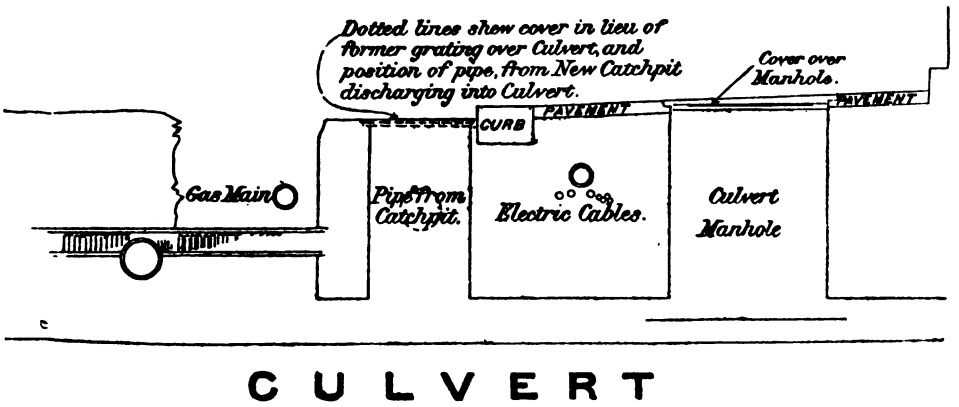
a quantity to form an explosive mixture, and that when the flame reaches a layer of explosive composition a violent explosion may result. It is, I think, quite possible this may have occurred in this instance, and that the person who threw the lighted match into the catchpit may be quite unaware that he thereby caused the explosion. The only other cause I can suggest is a spark struck by a horse's foot or a wheel close to the gully grating out of which the gas was issuing freely.

The explosion appears to have traversed the culvert and followed the course of the gas, which had percolated into the electric light street box, marked *a*, on the east side of bridge, whence it found its way by means of the pipes to those marked *b*, *c*, and *d*. The access to street box *a* appears to have been afforded by imperfect sealing round the pipes entering the box, which passed just over the culvert. This was tested by firing some smoke rockets inside this street box, when the smoke appeared in considerable volume at the culvert after about one minute, and seemed to be travelling along the outside of the pipes. Apparently on the west side the gas was unable to force its way into the electric light street box, but in this case the street box had only been constructed, and the pipes in connection with it laid, about a fortnight before the explosions occurred, and the pipes crossed at a greater height above the culvert.

attention in my report on the Cannon-street explosion in November last, greatly facilitates the passage of gas should it find access in considerable quantity at any point. This accident appears to me to suggest far more serious cause for anxiety than that which recently occurred in Cannon-street. It is true that in this case there was no electrical charging of the ground, or any defect in the electric lighting mains, and that the explosions were not due to any electrical action, but the Cannon-street accident was caused by a gross blunder on the part of the electric lighting company, and the company have since taken steps to make a repetition impossible.



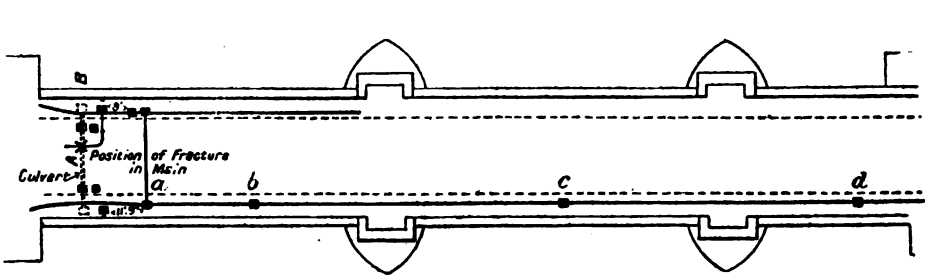
A.—Plan showing Pipes and Manholes where the explosions originated.



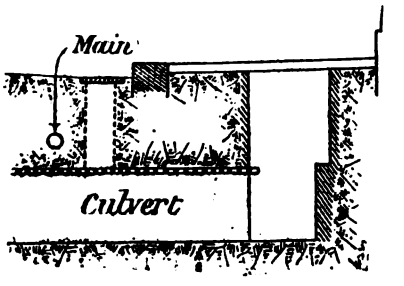
C U L V E R T

Section on Line A B.

The most striking features about the Southwark Bridge accident are: (1) the distance to which it appears that a series of explosions may travel along the electric mains which form a gigantic network under the whole of the streets of the City; and (2) the proof it affords of the insufficiency of any ordinary system of ventilation of these pipes and street boxes, if gas can find an easy access to them, and the necessity of exercising great care to make and keep the street boxes impervious to gas. The culvert which exploded in this case was provided by means of the catchpits and gully gratings with large openings for the escape of gas, and yet these did not prevent the explosion, and indeed probably enabled the accumulated gas to be fired. This culvert, however,



B.—Plan of Southwark Bridge showing Street-Boxes where explosions occurred.



Section on Line A B.

Having obtained access to street box *a*, the connecting pipes gave an easy passage to *b*, *c*, and *d*. As far as street box *c* the slope of the roadway favoured the passage of the gas, beyond that it was forced down the slope by the pressure from behind, and no doubt travelled more slowly. The explosion in *d* appears not to have been quite so violent as in *c*. Had more time been allowed for the penetration of the gas along the system of pipes, there is every reason to believe that more explosions would have occurred. The existence of numerous empty pipes in the system of mains laid by the City Electric Lighting Company, to which I called

so far from being impervious to gas, permitted it easy access through the openings of the grating forming the lid of the culvert.

After very careful consideration of the recent accident, I adhere to the recommendations as to prevention of accumulation of gas detailed in my report on the Cannon-street accident. Had these been carried out there would have been no explosion in the electric light conduits. I am, however, inclined to give more emphasis to the suggestion that the air capacity of the street boxes should be reduced by filling with incombustible material, and to add that unless and until an efficient system of ventilation by forced

Digitized by Google

draught is provided, all the pipes and conduits should be thoroughly plugged at each street box (as recommended by Major-General Webber, C.B.).

With this addition I can only repeat the requirement No 7 of my former report: "Accumulation of gas should be prevented by thorough ventilation, by making the sides and bottoms of street boxes impervious to gas, and by filling up the boxes as far as practicable with incombustible material." To this I would now add "by thoroughly plugging pipes and conduits at each street box to prevent passage of gas along the system," and I put the filling up the boxes first, as the most simple and certain method of preventing danger of explosion. In cases where the street boxes are completely filled up it will obviously not be necessary to adopt the other precautions.

So far the electric lighting company have done very little towards carrying out this requirement. It appears that only 18 street boxes have been provided with ventilating-pipes, and these are not, in the cases I have examined, carried up at least 8ft. from the ground as recommended by me, but terminate a few inches from the pavement. The company have, however, protected the orifices with a cap and a screen of fine wire gauze, which may sufficiently guard against the danger of the gas issuing from these pipes becoming ignited by a match carelessly thrown near them. It must be admitted that in this case the main cause of the explosions was the defect in the gas-pipe, and it again directs attention to the very serious danger to the public arising from the condition of the gas pipes in many districts, and the way in which they are laid and supported—a danger which is continually increasing owing to the spread of the use of wood paving and other impervious surfaces, and which is temporarily intensified by every severe frost.

No remissness on the part of the gas companies can, however, relieve the electric lighting company of the duty of thoroughly complying with regulations (14) and (15) by sufficiently protecting their conduits and street boxes against an accumulation of gas. How this may be done I have already specified in this report and in my report on the Cannon-street accident, and I recommend that the Board of Trade should require the City of London Electric Lighting Company to at once take the necessary measures to fully comply with the regulations imposed upon them by the Board of Trade for the protection of the public safety.

THE SELECT COMMITTEE ON TELEPHONY.

The Select Committee of the House of Commons appointed to consider and report whether the provision now made for the telephone service in local areas is adequate, and whether it is expedient to supplement or improve this provision either by the granting of licenses to local authorities or otherwise, met on Friday for the first time to hear evidence, Mr. A. Morley (Postmaster-General) occupying the chair.

Mr. G. C. Lamb, assistant secretary of the Post Office, who was examined by the **Chairman**, said that the telephone was first brought to this country by Lord Kelvin in 1876, but then in a very crude form. In 1878 the discovery of the microphone by Prof. Hughes made the telephone a practicable instrument, and a company was started for acquiring and working Bell's patent. In 1879 it sought an alliance with the Post Office, but the negotiations came to nothing, and in the autumn of 1879 the Edison Telephone Company announced that they intended to establish telephonic exchanges. The first exchange of the kind had been established in Chicago in the previous year. The Post Office immediately pointed out that the proposed operations would infringe the Postmaster-General's rights, and an information was filed against the Edison Company and the United Telephone Company. In June, 1880, the two companies amalgamated under the title of the latter. The legal proceedings were concluded in December, 1880, when judgment was given by the High Court of Justice in favour of the Post Office. In anticipation of this judgment, the Post Office had made arrangements to establish telephone exchanges of its own. At the same time negotiations with the telephone companies were opened for granting to them licenses. The licenses were to be granted under what was interpreted to be the authority of the Telegraph Act, 1869. The companies in accepting the license certainly accepted the judgment. If they had thought they would succeed on appeal, they would have appealed. In April, 1881, the United Telephone Company was granted a license to carry on telephone-exchange business in London. The area of its operations was to be five miles from a central point selected by the company, and a royalty was to be paid to the Post Office. The policy of the United Telephone Company was to confine its own exchange operations to London, and to allow its patent rights to be used in other parts of the country by subsidiary companies, which negotiated themselves for licenses. The company had a practical monopoly of the best telephonic apparatus. Licenses were granted to provincial companies, and all of them were for 31 years from the date of the original license, and all would expire at the end of 1911. The Post Office also established telephone exchanges of its own in several additional towns, among others Cardiff and Newport. Up to that time there had been no trunk wires between the large towns, but in 1881 a few were provided by the Post Office at a fixed annual rate. The licenses were restricted to areas, and no company had power to construct trunk wires. In 1882 the London Globe Telephone Company applied for a license in London, and, though the United Telephone Company objected to competition, the license was granted, and in the same year the Postmaster-General granted licenses for the establishment of exchanges even in towns such as Newcastle, where the Post Office had exchanges of its own. In 1884 the London Globe Company was absorbed by the United Telephone Company. In July, after consultation with the companies, Mr. Fawcett sought the authority of the Treasury to abolish all restrictions of areas and to throw the whole country open to the operations of licensees. The arrangement was sanctioned in August, 1884; and, as a result, the licenses now held by the companies were given in substitution of the old and original licenses. They were terminable at six months' notice in 1907. The main difference between the "Fawcett" licenses and the original licenses was that the former were for the whole country, and authorised the erection of trunk wires. Altogether 23 licenses were granted, and at present 13 were in existence. But, as a matter of fact, all the companies holding those licenses had been absorbed either by the National Telephone Company or the New Telephone Company, and as the National Company held nearly all the shares in the New Company, which was now in process of liquidation, it might be taken that for all practical purposes there was only one company in existence. The late Government were led to consider the question of fresh arrangements by the public dissatisfaction with the service which the telephone companies were rendering, and by the alarm of the public at the uncontrolled monopoly which was gradually being created. They were also influenced by the repeated demands of the companies for further powers, and by the effect which the competition of the telephone companies was having on the telegraph revenue. In the six years 1886-91 the gross revenue of the companies rose from £261,000 to £465,000, while the net telegraph revenue was going down. In the year 1888-89 there was a balance of revenue over expenditure in the telegraph business of the country of about £88,000. In the following year that decreased to £85,000, and in the next year ot £68,000. In the year 1892 the balance of £68,000 was converted into adeficiency of £90,000. His own view was that that was largely due to the competition of the telephones. In 1886-91, while the business of the companies increased 77 per cent., the ordinary inland business of the Department increased only 44 per cent. The deficiency in the telegraph service for the year 1893-94 rose to £178,000, and it was estimated that in the year 1894 95 the deficiency would further increase to £240,000. He could not contend that the telephone competition accounted for the whole of that deficiency, but for a substantial part of it. The royalty paid in the year 1894 was £70,900; in 1891, £46,500; and in 1886, £26,100. The late Government did not see their way to purchase the companies' undertaking at the end of the first period mentioned in the license, which was 1890. After much consideration they adopted the policy set forth in the Treasury minute of 1892. Their intention was to facilitate the operations of the companies by conferring certain powers of constructing telegraphs enjoyed by the Postmaster-General; to give additional facilities to the public by a closer combination of the telephone systems with the postal and telegraph systems of the Post Office; to safeguard the interests of the telegraphs by erecting trunk lines between the different towns; and further to extend the trunk lines so as to bring into communication the most distant places in England and Ireland. The right of the Post Office to establish telephone systems was fully preserved. A Bill was introduced authorising the acquisition of the companies' trunk wires, and providing capital for the building of other trunk wires. Certain powers of wayleave were also conferred on the companies. This Bill became law as the Telegraph Act of 1892. In reporting to the House that the responsibility for the details of the agreement must rest with the Government, the committee made the reservation that the duration of the licenses should not be extended. The heads of the arrangement with the companies were signed in August, 1892. The Department had now expended about £374,000 on the erection of trunk wires It had completed the connection between Plymouth, Bristol, and the South Wales ports with Birmingham, Leeds, and Newcastle-on-Tyne. It had also completed lines from Hull to Leeds, and from Leeds to Manchester and Liverpool; from London to Chelmsford, Colchester, and Ipswich; from London to Brighton, Nottingham Derby, and Leicester; and from Edinburgh and Glasgow to Belfast and Dublin. Lines connecting London with Bristol, Southampton, and Portsmouth were in hand; and a main line from London through Nottingham, Sheffield, and Leeds to Glasgow would, it was hoped, be completed early next month. This direct communication between London and Glasgow, and consequently with the towns in communication with Glasgow, was something entirely new. In addition to this main system, about 50 lines of minor importance had been constructed or were in process of construction. Under the agreement the Postmaster-General took over the trunk lines of the companies, and would pay a sum to be fixed by experts, and the operations of the companies would be limited to specified exchange areas. The companies were to construct connecting wires from their exchanges to the post offices to enable their customers to make use of the public wires for the conveyance of telegrams and the delivery of express letters. For the working of these connecting wires the Postmaster-General made no charge, and he was to provide underground wires between exchanges situate in the same area. Further, he was to give permission to the companies to make agreements with the railway and canal companies over whose property he had exclusive rights of way for the construction by the companies of telephone wires, and they were to pay him merely a nominal rental of 1s. per mile instead of 20s. per mile as was before provided. This concession involved a reduction in the payments made by the company to the Department of about £2,400 a year. The power of the Postmaster-General to provide telephone exchanges, or to allow others to do so,

Digitized by Google

was fully reserved. The result of the agreement would be that there would be a complete national system of telephonic communication throughout Great Britain, and between Great Britain and Ireland, and there would be placed at the disposal of the public facilities, not only for telephonic intercommunication, but for a combination of the telephone and the telegraphic and postal services of the State. The development of town intercommunication would be in the hands of the Post Office, and the development of the local exchanges would be in the hands of the companies. It was obvious that the taking over of the trunk wires by the Post Office was a step in the direction of the acquisition of the telephones. He believed that both reason and experience pointed to the necessity for only one exchange system within one area. As a matter of fact, every competing company that had been established had been absorbed by some existing company. It was obvious that, if efficiency and economy were looked for, only one system in one area should be provided. If those who used the telephone in any place were divided into two groups, those belonging to one group could not communicate with those belonging to the other, unless they subscribed to both systems. In Christiania they had two competing companies, and the municipality brought all its influence to bear on them to make them combine. There was no difference of opinion among experts that competing systems in one area must result in inconvenience to the public and in expense and want of efficiency. It was a fact that the deficiency in the telegraph revenue was arrived at after all the money for extensions had been paid out of the revenue of the year, excepting what remained of the capital provided by the Act of 1892. There had also been an enormous increase in the staff and in the wages of the Post Office during the past 10 years. Commercial depression would not affect the telegraph receipts more than the telephone receipts, but it was natural that the extension of telephonic communication should cause a diminution in telegraph receipts. The witness said that without any breach of honour or faith the Post Office could grant additional licenses. The Post Office had maintained the right to create competition.

BRAY (IRELAND) ELECTRIC LIGHTING BILL.

BILL OR PROVISIONAL ORDER.

The Bray Township Improvement Bill was considered by a Select Committee of the House of Commons last week under the presidency of Sir J. Kitson.

Mr. Hopwood, of the Board of Trade, said he had been asked to attend before the committee to make a statement of the views of the Board with reference to the application of the promoters to take electric lighting powers by the Bill rather than by a provisional order. He had no intention to oppose the promoters in any way, but the Board of Trade thought it their duty to lay before the committee the view which they had taken on this subject since the passing of the Electric Lighting Act of 1882. The Board held that electric lighting legislation was of a technical and quasi-scientific character. They admitted that the Act of 1882 contemplated that promoters might apply for powers by Bill equally with provisional orders, but they thought it would be much better to adopt a uniform system of provisional order legislation. It should be borne in mind that Parliament had an opportunity of expressing an opinion upon the terms of the Board of Trade orders when they came before Parliament for confirmation by Bill. The Board's provisional orders for electric lighting had been very carefully prepared, and they contained stipulations and provisions of all kinds to meet the requirements of different places and different sections of the community, and he might fairly say that a uniform system of provisional orders was now in force throughout the country. The question was whether it would be well to have, he would not say a dual control, but a dual procedure. The Board of Trade were quite prepared to admit that exceptional circumstances might arise in which it might be expedient to admit promoters to obtain powers of this description by Bill; in fact, there had been one such case in connection with a London company. So far as the present Bill was concerned the Board of Trade recognised that there were exceptional circumstances. It appeared that the promoters had exhausted their borrowing powers, and he took it that it would be impossible for the Board of Trade by order to enable the promoters to raise the necessary money to light Bray. On the other hand, it might be said that the circumstances were not sufficiently extraordinary to warrant a reversal of the ordinary procedure which had been adopted, because the promoters might very well apply to the House by this Bill for power to borrow money, and then go to the Board of Trade for a provisional order. Whether that would be looking at it from a purely business point of view was a question for the committee to decide. If the committee saw fit to recognise exceptional circumstances in this case he would ask them to impose the obligation on the promoters of making their Bill, so far as the electric lighting provisions were concerned, as far as possible, identical with the Board of Trade model orders.

Mr. Littler, Q.C., interposing, declared the willingness of the promoters to comply with that suggestion.

Mr. Hopwood said it would then really rest with the committee to say whether they thought that the circumstances there were so exceptional as to permit of the reversal of the policy which had been adopted up to the present time. He would also invite the committee, in case they came to the conclusion that the exceptional circumstances in that case justified the Bill, to say that it was not to be treated as a precedent. At present the terms of the Bill did not conform to the terms of the Board of Trade orders. For instance, there was no provision imposing a penalty for failure to supply. There was another question as to the area of supply. He gathered that a part of that area was outside the district of the Commissioners, and it was not quite clear how the promoters would deal with that matter, and what provision they would make for the protection of local authorities outside their own district.

Mr. Littler reiterated that the Commissioners were desirous of complying with the requirements of the Board of Trade, and if Mr. Hopwood would favour the promoters with a short interview he had no doubt they would be able to agree as to the form which the electric lighting clauses should take. If they found there was any serious difference between them they must refer the point to the committee, but he did not anticipate any such difficulty.

Mr. Hopwood expressed his willingness to consult with the promoters, and

The **Chairman** said the committee recognised that the circumstances were exceptional. The capital was very small, and it would not seem right to compel the promoters to go for a provisional order, which would probably cost them £300, or 10 per cent. on the amount they were going to give for the electric lighting plant.

Mr. Patrick M'Donnell, town clerk of Bray, said that by the present Bill the Commissioners were asking power to borrow £20,000 for the completion of the harbour, £6,000 for electric lighting, and £12,000 for the general purposes of the township. The electric lighting works at Bray were established three years ago. The Commissioners invited tenders for lighting the town, and Messrs. Gordon and Co. obtained the contract. Afterwards Mr. Gordon died, and the firm became insolvent. The Commissioners had now made a very good bargain with the liquidators to purchase the whole business, buildings, and plant for £3,060, but the agreement, which had been approved by the Court of Chancery, was conditional upon that Bill being pushed through this session. At present, although the public lamps were supplied with the electric light, very few shops or private houses had got it. They were afraid to go to the expense of having the proper fittings, etc, put in for fear the company should burst up, which it had done; but they knew that many householders were only waiting to have the electric light laid on until such time as the Commissioners took over the control and responsibility. The working expenses would be less under the Commissioners than they were under a private firm. Even if the consumption remained as it was, it was calculated that they would make £500 a year profit. The taking over of the electric light by the Commissioners was approved almost unanimously by the ratepayers at a town's meeting.

Witness was cross-examined by **Mr. P. Stephens** as to the correctness of his figures, and evidence was then called on behalf of the opposing railway company.

After the committee had consulted for some time in private,

The **Chairman** announced that the committee were agreed that the preamble of the Bill had been proved, but, having regard to the evidence of the town clerk that the general borrowing powers had not yet been exhausted, they wished to prevent those powers being further exercised. With regard to the electric lighting powers asked for, the committee agreed with the view expressed by Mr. Hopwood, on behalf of the Board of Trade, that in the absence of special circumstances such power should be obtained by provisional order, and not by Bill; but, recognising that exceptional circumstances existed in this case, the committee would report in favour of the powers asked for being granted, providing that the Bill followed as far as possible the terms of the model order of the Board of Trade, and that the concession in this case was not treated as a precedent.

Mr. Littler, Q.C., for the promoters, expressed their readiness to meet any suggestions the Board of Trade might choose to insert in the clauses.

The arrangement of the clauses in detail was postponed.

BRISTOL CORPORATION ELECTRICITY WORKS.

The accounts have been issued of the working of the electric light station of the Bristol Corporation during the year ended December 31, 1894. It appears that the expenditure during the past year reached £32,203, and that the total expenditure to December 31, 1894, has amounted to £82,186. Below are given the revenue account and balance sheet:

REVENUE ACCOUNT, YEAR ENDING DEC. 31, 1894.

A.—To Generation of Electricity.

Dr.	£ s. d.	£ s. d.
Coal, or other fuel, including dues, carriage, unloading, storing, and all expenses of placing the same on the works	1,529 18 7	
Oil, waste, water, and engine-room stores	185 17 1

LEGAL INTELLIGENCE.

BARCLAY v. THE NEW ZEALAND ELECTRICAL SYNDICATE.

In the Chancery Division of the High Court of Justice last week, before Mr. Justice North, a motion was heard for the appointment of a receiver and manager of the business of the defendant company, the plaintiffs being the holders of the whole of the debenture issue.

Mr. Stewart Smith said he appeared for the company, and submitted to the order.

Mr. O'Leigh Clare claimed to appear for the company, and objected to the order, his point being that the two directors for whom he appeared were the only real representatives of the company, and that they had commenced an action in the Queen's Bench Division to restrain the gentlemen who were instructing Mr. Smith from acting as directors on the ground that they had transferred their qualification shares before they attempted to act.

In support of the motion, **Mr. Swinfen Eady** said that the plaintiffs had £30,000 of debentures, which were charged on the undertaking of the company. The debentures were not in terms due; but the case made was one of great jeopardy, because unless the appointment asked for were made, the valuable concession and plant of the company might be forfeited.

Mr. Justice North made the order asked for, referring the matter to chambers for the appointment of a particular person, but appointing Mr. Barclay, the first plaintiff, interim receiver.

Later in the day, in the same matter, as Mr. Justice Kekewich was sitting, **Mr. Leigh Clare** asked for leave to serve short notice of motion for Tuesday for an injunction to restrain the two alleged directors from purporting to act in that capacity.

His **Lordship** said he would give leave to serve notice of motion for next Friday (to-day), with leave also to amend the writ asking for an alteration of the register.

WISE v. METROPOLITAN ELECTRIC SUPPLY COMPANY.

This case came before Mr. Justice Stirling in the Chancery Division of the High Court of Justice last week. It was a motion for a writ of sequestration against the company for alleged breach of an injunction restraining them from carrying on their business in such a way as to cause a nuisance to the plaintiffs by vibration. The plaintiffs are lodging-house keepers residing in the neighbourhood of Manchester-street, and their case against the company is that the vibration caused by the electric lighting machinery is such as to constitute a serious nuisance and injury to them. The injunction was granted in April last, but its operation has from time to time been suspended in order to give the defendants the opportunity of abating the nuisance by means of alterations in their machinery and otherwise. The last occasion on which the case came before the Court was in November, 1894, when the company gave an undertaking not to use more than one reciprocating engine in addition to certain steam turbines which had been substituted for the original engines. The plaintiffs now alleged that the nuisance still continued, and they pressed for the issue of a writ of sequestration.

Mr. Hastings, Q.C., and Mr. Beaumont appeared for the plaintiffs.

Mr. Waggett (who, with Mr. Vernon Smith, Q.C., appeared for the company) contended that this was not a case for the exercise of so extreme a remedy as the issue of a writ of sequestration. There was evidence that the nuisance was much abated and that the vibration was now very slight, if it existed at all. If the plaintiffs were asking for an injunction on the present evidence it would not be granted, and still less would the Court make an order of sequestration. The company had ordered two additional and improved turbines, which would be delivered in June, when the company would be able to dispense with the reciprocating engine altogether.

Mr. Justice Stirling said that the vibration was clearly much diminished, but it appeared to be still perceptible at times. He thought that when it did occur it was caused by the use of the reciprocating engine. There was no evidence before him that it impossible for the company to carry on their work without the use of that engine, and instead of ordering a writ of sequestration to issue he should put the company on terms not to use the reciprocating engine, and they must pay the costs of the motion.

COMPANIES' MEETINGS AND REPORTS.

W. T. HENLEY'S TELEGRAPH WORKS, LIMITED.

The annual general meeting was held last week at the offices, 27, Martin's-lane, Cannon-street, E.C., Mr. Sydney Gedge presiding.

The **Chairman**, in moving the adoption of the report (which was published in our last issue), congratulated the shareholders on the satisfactory result of the past year. He said that they were doing a steady and increasing business. Not only had the business increased, as compared with the previous year, but the ratio of profits had also advanced. The reason why they were able to sell at low prices and get better profits was because their works were well managed. The directors had now written off the shares they held in the International Cable Company, which amounted to £48,200, and he was happy to say that a substantial sum was expected from that source. The whole of the share capital had now been placed. The result of the year's working was a net profit of £16,455. After paying the expenses of issuing the debenture stock and the dividend on the preference shares, there remained £15,957. Out of that the directors proposed to add £2,180 to the reserve fund, to pay a further half-year's dividend on the preference shares at the rate of 7 per cent. per annum, a dividend on the ordinary shares of 7 per cent. per annum, and carry forward £8,624. During the current year the business of the Company showed a satisfactory increase.

The motion was seconded and carried.

Mr. R. J. Jenkins, C.E., and the Hon. Randolph Stewart, who retired by rotation, were re-elected directors, and a vote of thanks to the chairman and Board closed the proceedings.

EASTBOURNE ELECTRIC LIGHT COMPANY, LIMITED.

Directors: George Boulton (chairman), James George Langham, James Arthur Skinner, Harry Sutton. Manager, Henry Wall Wilkinson, A.M.I.C.E. Secretary, Henry Towner.

Report of the directors presented to the shareholders at the ordinary general meeting of the Company.

The directors have to congratulate the shareholders upon the

Digitized by Google

extremely satisfactory progress of the Company. At the close of 1894 the number of lamps in circuit was as follows: arcs, 35; incandescents of an average of 8 c.p., 12,056—an increase for the year of eight arc and 2,179 incandescent lamps. The gross earnings for the year amounted to £5,910. 10s. 9d., and the expenditure (including £400 carried to the depreciation fund account) to £3,337. 0s. 9d.—giving a gross profit upon the actual working of the Company of £2,573. 10s. After adding thereto the reserve of £295. 13s. 8d. from last year's profits, and providing for all mortgage and debenture interest, a balance of £1,540. 11s. 4d. remains. Out of this the directors propose to set apart a sum of £300 to form the nucleus of a reserve fund for meeting any contingency which may arise, and it may also be applied in part from time to time to the reduction of the debenture issue. This will leave £1,240. 11s. 4d. out of which to pay the dividend, and the directors propose that a dividend at the rate of £7. 10s. per cent. per annum, free of income tax, absorbing £798. 15s., be declared upon the share capital of the Company. The balance of £441. 16s. 4d. will be carried to next year's net revenue account. The depreciation fund account now stands at £1,825. Since the last annual meeting the Company's circuits have been extended to Upperton and they now run through the following roads: The Avenue, Carew-road, Hartfield-road, Enys-road, St. Anne's-road, Arundel-road, Mill Gap, Selwyn-road, Upperton-road, Moat Croft-road, High-street, and the Goffs. The first lighting of the Upperton district took place on October 10 last. The light has been installed at St. Mary's parish church and at several private houses at Upperton, and a large addition to the roll of customers is hoped for during the coming spring. The capital for the Upperton extension was provided by the issue of debentures, all of which were privately subscribed. The Company's machinery, circuits, and mains are in excellent condition. Mr. James Arthur Skinner retires from the direction this year, but, being eligible, offers himself for re election. The auditors, Messrs. Hart Bros., Tibbetts, and Co., also retire, but may be re-elected.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Norwich.—The Town Council require by April 2 tenders for the supply of two Galloway boilers and the installation of electric light fittings at the new baths.

Dublin.—Among the stores for which tenders are invited by the Dublin, Wicklow, and Wexford Railway Company, are cylinder oil, cotton waste, indiarubber, and varnishes.

Manchester.—The Lancashire and Yorkshire Railway Company require by the 30th April tenders for the supply of an oil-engine, engine packing, signal and telegraph fittings, signal, telegraph and electric light wires, wire, etc.

Stowmarket.—The Urban District Council require by April 15 tenders for lighting the streets of Stowmarket from August 15 next to May 15, 1896, and also for lighting the post office clock. Particulars may be had of Mr. S. Prentice, clerk.

Worcester.—The Corporation invite tenders by April 6 for wiring Victoria Institute. Copies of specification may be obtained from the architects, Messrs. Simpson and Milner-Allen, 10, New-inn, Strand, London, W.C, accompanied by a deposit of £1. 1s. Plans of the lighting system may be seen at their offices, and on the works. Tenders are to be delivered at the offices of the architects.

Leicester.—The Gas and Electric Lighting Committee of the Corporation require by April 6 tenders for the supply of about 6,000 yards of high and low pressure cables. Specification and form of tender may be obtained upon application to the engineer, Mr. Alfred Colson, M.I C.E., Gas and Electric Lighting Offices, Millstone-lane, Leicester. Tenders are to be addressed to Alderman Lennard, chairman, and endorsed "Tender for Cables."

Rangoon.—Tenders will be received by the president of the Rangoon Municipal Committee, not later than November 4, for the lighting of Rangoon by electricity. Tenders should be accompanied by detailed plans, specifications, and estimates, and must state the terms on which the installation proposed will be undertaken. All information regarding the existing system of lighting and the cost, etc., with plan of the town, can be obtained on application to Messrs. Ogilvy, Gillanders, and Co., Sun-court, 67, Cornhill, London, E.C., accompanied by a remittance of £1. 1s. Tenders are to be sent in sealed covers and endorsed "Tender for Electric Lighting, Rangoon." Mr. J. Short, Rangoon, is the secretary of the committee.

RESULTS OF TENDERS.

Stafford.—The tender of the Electric Construction Company for a switchboard has been accepted by the Town Council.

Southport.—The Town Council have accepted the following tenders for additions to engine and boiler house at the electricity works: Section 1, H. Connard, Southport, brickwork, etc., £564; Section 2, J. Blanchard and Sons, Southport, joinery, etc., £541; Section 3, E. Wood, Manchester, ironwork, £669.

BUSINESS NOTES.

New Hartley.—The New Hartley Colliery is now lighted by electricity.

Western and Brazilian Telegraph Company.—The receipts for the past week were £3,411.

Bangor.—The Gas Committee have again discussed the question of electric lighting, and a report thereon is to be made at the next meeting.

Sunderland.—The Finance Committee of the Corporation have passed accounts which included £1,200 for dynamos and electrical apparatus.

Great Northern Telegraph Company.—The ordinary general meeting will be held in Copenhagen on Saturday, April 20, at 3 p.m., at the Exchange.

Digitized by Google

West Cowes.—A report on the proposed electric lighting of the town has been prepared by the surveyor.

Engineering Business for Disposal —Mr. Simpson, auctioneer, of New Cross-gate, S.E., has particulars of a small engineering business in London for disposal.

Limerick.—A report for presentation to the Corporation Gas Committee is being prepared by Prof. Kennedy. The Corporation already possess electric lighting powers.

Willans and Robinson.—The registers of transfers and members of Willans and Robinson, Limited, are closed, prior to the third ordinary general meeting, to the 10th prox.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 24th inst. amounted to £943, as compared with £797 in the corresponding week of last year.

King's Lynn.—Mr. Jermyn has given notice to the Town Council to move at the next meeting that they apply for powers to introduce an electric light installation in the borough.

Chiswick.—The Works Committee reported to the District Council last week that the surveyor had announced that the works at the electric light station were progressing satisfactorily.

Luton.—The clerk reported to the Town Council last week that the Board of Trade had granted the Luton Corporation electric lighting order, and that it would be put in the first confirming Bill.

Bray (Ireland).—The Town Commissioners have been authorised to acquire and work telephones subject to the insertion in their Bill of a clause for the protection of the Dublin, Wicklow, and Wexford Railway Company.

General Traction Company, Limited.—This Company has been registered, with a capital of £7 in £1 shares, to acquire contracts grants, concessions, etc , for the construction of rail and tram roads, telegraphs, telephones, etc.

St. Luke's E C.—The Vestry have received a communication from Mr. Baker, one of St. Luke's representatives at the London County Council, stating that that body had refused to sanction the plans of the electric lighting company in the City-road.

Norwich.—In reply to a question at a meeting of the Town Council in regard to the proposed sewerage scheme, Mr. A. E. Collins, the city engineer, stated that he was not prepared to say whether pumping by electricity was cheaper than the use of Shone's ejectors.

J. G. Bartlett and Co., Limited.—This Company has been registered, with a capital of £2 000 in £1 shares, to acquire the business of mechanical, electrical, hydraulic, and general engineer, as hitherto carried on by Messrs. J. G. Bartlett and Co., at Redcliff Wharf, Bristol.

Dover.—The Dover Electrical Supply Company are making progress with their works. The company have already made arrangements for the lighting of Dover Admiralty Pier, and negotiations are in progress with the military authorities for installing the light in all the barracks.

Ossett.—A conference of representatives of public bodies at Ossett and Horbury was held on Monday, at the Ossett Technical School, to consider the question of the gas supply. It was mentioned that the question of electric lighting would shortly be brought before the authorities of both townships.

City and South London Railway.—The receipts of the Company for the week ended March 24 were £893, against £792 for the corresponding week of 1894, or an increase of £101 The total receipts for the current period of the present half-year are £11,716, against £11,192 in the corresponding period of 1894, an increase of £524.

Eastern Telegraph Company.—The Company announce the payment on April 11 of interest of 3s. per share, being at the rate of 6 per cent. per annum, on the preference shares, for the quarter ending March 31; and the usual interim dividend of 2s. 6d. per share on the ordinary shares for the quarter ended December 31.

Appointment Vacant.—As will be seen by our advertisement columns, the Vestry of Saint Mary, Islington, invite applications for the temporary post of canvasser. The salary offered is £3 per week and commission. Applications are to be addressed to the electrical engineer, 50, Eden-grove, Holloway, N., not later than Wednesday, April 3.

St. Olave's, S.W.—The Works and Finance Committee reported to the Board of Works last week that the clerk and surveyor had met the solicitor of the County of London and Brush Provincial Electric Lighting Company, Limited, in conference before Sir T. W. B. Blomefield, of the Board of Trade, and had agreed to certain amendments to the St. Olave's provisional order. The Board approved of the order as amended.

McPhail and Simpsons' Steam Patents.—Under the title of McPhail and Simpsons' Dry-Steam Patents Company, Limited, a company has been formed, with a share capital of £416,000, for the purpose of acquiring the business, plant, stock, royalties, goodwill, and patents of Messrs. McPhail and Simpsons, of Wakefield. The patents are directed to the perfection of a method of producing dry and superheated steam at a controllable temperature.

Yarmouth.—An installation of the electric light has been put up in the drapery establishment of Messrs. Palmer Bros. The order for the work was entrusted to Messrs. Laurence, Scott, and Co., of Norwich, and Regent street, Yarmouth, who have carried it out under the management of their agent there, Mr. Reavell. The scheme of lighting the windows embraces the use in the whole installation of 61 16-c.p. lamps distributed in groups of three and four, and shaded with white porcelain shades.

Stafford.—The Town Council last week adopted a report of the Electric Lighting Committee recommending the acceptance of the tender of the Electric Construction Company for a switchboard, and of Messrs. C. and W. Walker for an overhead tank to contain 12,000 gallons at a cost of £117. The committee also presented the regulations and conditions as to wiring consumers' premises, and asked for leave to authorise the engineer to purchase the necessary fittings, so that the wiring of premises may be begun at once.

Heanor.—The electric light has recently been substituted for gas in the factory of Messrs. J. Fletcher and Sons, of Heanor and Nottingham. The dynamo is driven by the 30 h.p. engine which drives the lace machinery. The dynamo has a capacity of 200 lights. The offices, drafting-rooms, and engine-houses are lighted by lamps of 16 c p. and 32 c.p,, and the lace machines have two 32-c.p. lamps each. The installation has been carried out by Messrs. Thomas, Danks, and Co., Limited, of Thurland-street, Nottingham.

Direct Spanish Telegraph Company.—The report for the half-year ended December 31 states that, after providing for debenture interest and redemption of debentures, there is a balance to the credit of revenue of £4,077. After adding the usual sum of £2,500 to the reserve fund the balance of revenue amounts to £1,577. To this the directors propose to add £1,166 from interest on investments, and recommend the payment of the dividend at the rate of 10 per cent. per annum on the preference, and a dividend at the rate of 4 per cent. per annum on the ordinary shares.

Newport (Mon.)—It is stated that the day-load plant of the Corporation has been tested, and found satisfactory. This plant consists of a semi-portable engine of 50-i.h.p., cylinders 9in. and 14in., 16in stroke, and running at 135 revolutions per minute. The output of the alternator is 12½ amperes at 2,000 volts. The provisional plant has been handed over to the Corporation. The foundations for the larger machinery are practically complete, and the engines it is expected will be ready in a month, whilst the street lamps may be expected to be ready in two months.

Epstein Accumulators —The Epstein Electric Accumulator Company, Limited, of 215, Gresham House, Old Broad-street, E.C., give warning that plates are being offered by other makers of accumulators which are essentially Epstein plates, and they therefore caution users against employing plates which are made by infringing patents owned by them. Opinions in support of the validity of the Epstein letters patent have been given by Sir Richard Webster, Q.C., M.P.; Sir Horace Davey, Q C. (Lord Davey); Mr. Fletcher Moulton, Q.C , M.P.; Mr. Aston, Q.C.; and Mr. R. W. Wallace.

Foyers.—One of the directors of the British Aluminium Company, Mr. E. Ristori, A.M.I.C.E., has been engaged in making enquiries as to the operations which the company propose to carry out in the valley of the Foyers. A public meeting has passed resolutions approving of the establishment of the new industry in the district. Mr. Peregrine Birch, C.E., London, engineer to the company, accompanied by Mr. Graham and assistant, has been engaged at Foyers in surveying the ground and preparing the necessary plans for the excavations and embankments, and for the erection of the proposed works.

Bankruptcy Proceedings.—A first meeting under the failure of Mr. G. F. Rogers took place before the Official Receiver on Monday. The debtor, a telegraph engineer and general merchant, of Great Winchester-street, furnished accounts showing liabilities £27,982 (£19,800 expected to rank), and assets £264. He has also acted as director of public companies, and attributes his failure to liability on accommodation bills, for which he received no consideration, to loss in trading and investments and depreciation in value of securities held by creditors. A trustee and committee of inspection were appointed to wind up the estate in bankruptcy.

Richmond (Surrey).—A Local Government Board enquiry has been held upon the application of the Town Council for sanction to borrow £900 for fire brigade purposes. The Town Council was represented by Mr. Senior, assisted by Mr. Urquhart (of Messrs. Urquhart and Small, the electrical engineers to the Council), Mr. Brierley (the borough surveyor), and Mr Penn Lewis (borough accountant). Mr. Senior explained that some part of the £900 now asked for was required to complete payment for work already done, which had cost more than was originally anticipated. The cables for the fire-calls were estimated at £970, but the contract price was £980 and the actual cost £995 The call-posts were estimated at £230, but were contracted for at £265, and they ultimately cost £297, owing to the fact that an alarm was fitted inside the Town Hall, in addition to a post in the vicinity.

Manchester.—An enquiry was held last week by Colonel A. G. Durnford, on behalf of the Local Government Board, to hear evidence on the proposal of the City Council to borrow £100,000 for electric lighting purposes, and lesser sums for other schemes. Alderman Gibson, chairman of the Gas Committee, said that the £150,000 sanctioned by the Local Government Board for electric lighting purposes in 1892-93 had been overspent by about £14,000. In calculating that a plant equal to the supply of 20,000 16-c p. lamps would be sufficient for three years they reckoned without their host They were at once overwhelmed with applicants, and their energies had been and still were taxed to the utmost In September, 1893, they had 82 customers consuming energy equal to 4,000 16-c.p. lamps, and in February last 706 customers with 32,528 lamps. On the 12th of the present month they had 41 more applicants waiting to be connected, which would make a total of 747 customers consuming energy equal to 34,528 16-c.p. lamps. But they had another inducement. In the year from March, 1894, to March, 1895, they would be able to show a profit

Digitized by Google

after deducting interest and sinking fund of between £7,000 and £8,000. Mr. Alderman Lloyd Higginbottom, deputy chairman of the committee, explained in detail the way in which it was proposed to spend the £100,000. He stated that the committee had decided that in the forthcoming year the price per unit should be reduced from 8d to 6d.

Edinburgh.—A sub-committee of the Town Council on electric light had before them last week a report by Prof. Kennedy on the extension of the electric light system by running cables along Princes-street and out the bridges to Nicolson-street and Clerk-street, the Grange and Morningside, so as to join the present system at the Barclay Church The report also embraced the question of extending the light to the Royal and Regent terraces and George square. The probable cost is set down at about £4,000. So far the question is only under consideration, and the committee has made no recommendation. The Town Council sub-committee in charge of the electric lighting had under discussion on Tuesday, Councillor Douglas's motion to consider and report whether any steps should be taken to secure that any faults in gas-mains and service pipes shall be detected and removed without delay. It was agreed that the special attention of the Gas Commission be called to the large amount of leakage of gas which takes place, and the desirableness of examining old pipes and renewing them, so as to give more security now that electric lighting is introduced. The committee were of opinion that the subsoil of Edinburgh was very much saturated with gas which had escaped, and it was stated that everything that could be done with regard to making tight the mains and conduits for the electric light had been done. The date of turning on the electric light was changed from the 10th to the 11th April.

Electric Pumping Machinery—The Lothian Coal Company, Newbattle Collieries, Dalkeith, N.B., have given an order to Messrs. Ernest Scott and Mountain, Limited, of Newcastle-on-Tyne, for another large set of pumping machinery. About two years since the same firm placed a contract with this company for two sets of pumping machinery, each set to deliver 200 gallons per minute against a head of about 700ft., the plant consisting of two horizontal engines, each of 120 effective horse-power, with dynamos, motors, and three-throw ram pumps of their improved type. This plant has given such satisfaction, and has proved so economical in working, that the firm have now given the present order to Messrs. Scott and Mountain, so that the plant, when completed, will be capable of delivering 600 gallons per minute against a head of 700ft., but in case of emergency it could be considerably pressed. The company also have an order in hand for an extension of the electric pumping plant which they supplied to the Cambois Colliery, Northumberland, and are supplying a dynamo and electric motor with gearing complete for driving a pump which has hitherto been driven by wire ropes at Newton Colliery, Felton, Northumberland. The company are busy in their engineering department, having orders in hand for the pumping machinery for H.M.S. "Venus" and "Diana," and also for H.M.S "Mars," and have recently completed for their agents in India two sets of stern-wheel machinery, and are in receipt of a third order for compound stern-wheel engines and boiler.

Cardiff.—A meeting of the Public Works Committee of the County Council was held on Tuesday for the purpose of appointing a deputation to appear before the Board of Trade with reference to the proposed by-laws for the government of telephone, telegraph, and other wires. Notices of objections to the by-laws had been received from the telephone company, the Rhymney Railway Company, the Bute Docks Company, the Taff Vale Railway Company, and the Great Western Railway Company, who all protested against the height at which it was proposed all wires should be carried. The Corporation asked for a minimum height of 35ft. in crossing roads and 25ft. elsewhere. The model by-laws adopted by other towns made the height 30ft. over roads and 18ft. elsewhere. After some discussion, it was decided to ask for the heights of 35ft. and 25ft., and a deputation was appointed to wait on the Board of Trade. A meeting of the Free Library Committee was held on Tuesday. It was mentioned that some time ago Mr. Massey was asked his opinion of a scheme which had been proposed for the electric lighting of the library. A long letter was read from Mr. Massey, in which he recommended a system of shaded lamps laid on the tables, which he said was the more comfortable and convenient mode as opposed to the question of appearances. He estimated the cost of the work at £500. The committee did not appear to agree with this scheme, preferring instead that the light should be arranged so as to give a distributed light over the whole of the various rooms. Eventually the matter was referred to the Lighting Sub-Committee.

Monmouth.—As mentioned in our last issue, a special meeting of the Town Council was held last week to receive Mr. Lailey's amended plans and estimates in connection with the joint drainage and electric lighting scheme, and to petition the Local Government Board for powers to borrow £20,000 with which to proceed with the work. The Mayor (W. Honeyfield, Esq.) presided, and there were also present the town clerk (Mr. T. R. Oakley) and the borough surveyor and inspector of nuisances (Mr. P. E. Wanklyn). A letter was read from Mr. Lailey, the engineer for the drainage part of the joint scheme, intimating that his estimate had been brought down to £5,965. The Mayor observed that the position, to his mind, resolved itself thus: Messrs. Bramwell and Harris offered to do the whole work for £18,000, and if they put the whole work in their hands they would have to add £200 to the cost as the amount of fees to be paid Mr. Lailey. Messrs. Bramwell and Harris's estimate for lighting and other work amounted to £12,200, for carrying out the whole scheme £18,400. Mr. Lailey's amended estimate, less £120, was £5,845, and that, with his 5 per cent. fees, which amounted to £292, came to £6,137, or with Messrs. Bramwell and Harris's £12,000, £18,335. So that the expense of following either course was practically the same. Personally he should be quite content to see the scheme progressing on its old lines; still, if it was the wish of the Council to put the whole work in Messrs. Bramwell and Harris's hands he would not stand in the way of it Alderman Vizard said that the difference being so very trivial, he proposed that Mr. Lailey's amended plans of March 6, 1895, be accepted. Mr. Hall seconded, and the resolution was agreed to unanimously. It was then agreed to apply for permission to borrow £20,000 to carry out the work.

Acton.—The District Council last week considered the offer of Messrs. New and Mayne to buy the Council's electric lighting order for £500. A letter was read from that firm suggesting as the basis of an agreement that in all the by-roads of the district 16-c p. incandescent electric lamps should be substituted for the existing gas lamps at an annual cost to the Council of £2. 18s. 6d. per lamp, that in the main road about 30 arc lamps, similar in lighting capacity to those used at Ealing, should be fixed, and that for them the Council should pay what they were now paying for gas lighting. Messrs New and Mayne further suggested that the Council should permit them to use 32 c.p. incandescent lamps in the main road after midnight. Mr. Buxton and Mr. Everitt pointed out that it was understood that the cost of the 16-c.p. electric lamps would be the same as that of the present gas lamps, and that the gas lamps at the present time cost only £2. 13s. each per annum. Mr. Rome replied that when the agreement was first discussed the cost of the gas lamps was £2. 18s. 6d., and Messrs. New and Mayne had evidently based their calculations on that price. The Surveyor said the firm were of opinion that the price of gas was likely to go up, and he had no doubt they would be very pleased to substitute for £2. 18s. 6d. the actual cost of the gas lamps, whatever it might be, when the agreement was actually signed. The surveyor further stated that he had ascertained that if the Council adopted incandescent gas lighting about as much gas would be burned as heretofore; the incandescent burners would cost 11s. each. As to the up-keep of the burners, at Kensington the Incandescent Gas Company had undertaken the maintenance of them for 12s. each per annum, but as they refused to undertake the work at Acton presumably that price was lower than the actual cost. Mr. Buxton protested against the proposal to tie the hands of the Council to a particular firm and system for 42 years. Mr. Rome felt that it would be a very great mistake for the Council to let the present chance slip. He would oppose to the utmost of his power any proposal that the Council should undertake the work themselves. After further discussion, Mr. Rome moved, and Mr. Miller seconded, that the terms of Messrs. New and Mayne's letter be accepted, subject to their agreeing to the adoption of a sliding scale of prices if the Council decided on that prior to the signing of the agreement. The motion was carried by nine votes against four.

Brighton.—An enquiry was held last week by Colonel J. T. Marsh into the application of the Council for sanction to borrow £48,100 for purposes of electric lighting. The town clerk (Mr. F. J. Tillstone) and the deputy town clerk (Mr. Hugo Talbot) represented the Corporation, the borough engineer and surveyor (Mr. F. J. C. May), the electrical engineer (Mr. Arthur Wright), and the borough accountant (Mr. H. M. Stevens) being also present. The Town Clerk, in opening the application, said the proposed loan of £48,100 for electric lighting might be divided into two sums—one of £42,900 for electric lighting within the powers of the Electric Lighting Act, and one of £5,200 for street-lighting under the Public Health Act. Having regard to the rapid increase in the demand on their generating plant, and the fact that last winter the existing works were only just sufficient to supply the demand, the Council thought it necessary to extend not only their generating plant, but also their generating building. Plans and estimates had been prepared for an extension estimated to cost £13,449, and the Council proposed to lay down additional plant at an estimated cost of £29,451, these two sums making up the £42,900 for the borrowing of which sanction was asked. It had been necessary to carry out portions of the work included in this estimate without waiting for the formal sanction of the Board, but these were all permanent works for which the Board would ordinarily grant a loan. Mr. F. J. C. May (borough engineer and surveyor) gave further details of the proposed extension of the electricity generating station and of the Madeira-terrace. He estimated the cost of the extension of the electricity station at £12,400, the cost of culverts for the mains and strong-room at the office at £936, of a weighbridge and fixing £105, making a total of £13 441, or, with an allowance for contingencies, £13,449. Mr. Arthur Wright (electrical engineer to the Corporation) gave details of the proposed extension of plant. It was, he said, proposed to put down six boilers of 250 h.p. capacity, the cost of which was estimated at £3,600. An economiser would be put down at a cost of £600, and the boilers would be fed by electrically-driven pumps at an estimated cost of £500. The cost of pipework connecting the new boilers with the existing system was estimated at £1,800, and the sum of £133 had already been spent on the governing gears of the present engines. The condensers, with the connecting pipes and pumps, would cost £2,500. It was proposed to provide two new steam dynamos, to cost altogether £5,500, and a spare armature costing £350 had been already provided; £5,619 was required for mains, the sum having been already spent or incurred in providing mains for streets not contemplated when the last loan was applied for; £400 was the estimated cost of laying on services to new consumers; and £1,455 was the cost of connecting consumers in 1894 in excess of the last loan. The cost of connecting the circuits of the proposed 115 arc

Digitized by Google

lamps for public lighting was estimated at £1,000, and £494 was for work already done, covering a great number of sundries. The sum of £1,900 was provided for contingencies in carrying out the new work. Of the £5,200 proposed to be spent on public street-lighting £1.300 was the estimated cost of the lamps, globes, and switches, £3,150 the estimated cost of supports and fixing, £570 for connections, and £160 for the connecting cable run in the lamp-posts.

PROVISIONAL PATENTS, 1895.

MARCH 18.

5665. **Improvements in electro-pneumatic and pneumatic movements for organs.** Vincent Willis, 6, Bream's-buildings, Chancery-lane, London.

MARCH 19.

5671. **Improved storage battery.** Charles Langstone, Ben Young, and Aimé van den Bogaerde, Perry Barr, Birmingham.

5693. **Improvements in and relating to electrical railways and tramways.** Fred Pentz Bergh and Charles Wakefield Tarbox, 70, Market-street, Manchester. (Complete specification.)

5699. **Improvements in electric arc lamps.** George Robert Mac Intire, 5, John Dalton-street, Manchester. (Complete specification.)

5700. **Improvements in electric arc lamps.** George Robert Mac Intire, 5, John Dalton-street, Manchester. (Complete specification.)

5701. **Improvements in electric arc lamps.** George Robert Mac Intire, 5, John Dalton-street, Manchester. (Complete specification.)

5722. **Improvements in electricity meters.** Hugo Hirst and James Thomas Baron, 73, St. Stephen's-road, Upton Park, London.

5742. **Apparatus for automatically limiting the speed of electric cars.** Louis S. Wright, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

5747. **Improvements in dynamometers.** Benjamin Franklin Perkins, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

MARCH 20.

5867. **Improvements in electrical signalling apparatus for use upon railways.** Henry James Price and Luiz de Moraes Gomes Ferreira, 4, South-street, Finsbury, London.

5868. **An improved secondary battery.** Henri Cardozo, 4, South-street, Finsbury, London.

5875. **Improvements in and relating to conduits for electrical conductors.** Francis Lauder Muirhead, 124, Chancery-lane, London.

5878. **Improvements in or connected with the distribution of electricity.** Charles Henry Wordingham, 5, Victoria-street, Westminster.

MARCH 21.

5892. **A device for the better regulation of electric currents.** John Henery Robottom and Frederic Charles Geary, Church Gresley, Burton-on-Trent.

5913. **Improvements in means for regulating the electric light in railway-coach compartments.** Robert Edwin Gill and William Hockly, 9, Broomsleigh-street, West Hampstead, London.

5927. **A means of transmitting electrical impulses from pencil marks on paper or like material, and of reducing the electrical resistance of paper.** Richard Joseph Crowley, 40, King's-bench, Queenstown.

5936. **A current collector for electrically-propelled railway or tramway vehicles.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Siemens and Halske, Germany.)

5939. **Improvements relating to automatic telegraphs.** Angus Fraser and the Eastern Telegraph Company, Limited, 124, Chancery-lane, London.

5964. **Improvements in the construction of galvanic battery elements or cells.** August Höller, 47, Lincoln's-inn-fields, London.

5965. **Improvements in or connected with electrolytic cells.** Edward Augustus Allen, 47, Lincoln's-inn fields, London.

MARCH 22.

5984. **Improvements in or relating to signalling and communicating by telephony, and in apparatus used therewith.** Harold James Bentley, 55, Market-street, Manchester

5998. **An improved cup-and-ball joint for electrically connecting and disconnecting electric light fittings** Robert Walter Braham, 60, Red Lion-street, Clerkenwell, London. (Complete specification.)

5999. **Improvements in the method of and in apparatus for electrically lighting miners' safety and other lamps.** John Peel, 8, Quality-court, Chancery-lane, London.

6000. **Improvements in the method of and in apparatus for electrically lighting miners' safety lamps.** John Peel, 8, Quality-court, Chancery-lane, London.

6004. **Improvements in telephones.** William Phillips Thompson, 6, Lord-street, Liverpool. (Emil Kirschke, Germany.)

6006. **Improvements in electric railways.** Peter Friedrich Cornelius Bernhard Pretzsch, 45, Southampton-buildings, Chancery-lane, London.

6007. **Controlling apparatus for electrically-propelled railway trains.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Siemens and Halske, Germany.) (Complete specification.)

6008. **Improvements in springs for electrical conductors.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Siemens and Halske, Germany.) (Complete specification.)

6010. **Improved form of magnetic clutch.** Bernard Mervyn Drake, John Marshall Gorham, and H. Capel L. Holden, 66, Victoria-street, Westminster.

MARCH 23.

6035. **Non-resisting electric conductors** John Alexander Rossiter, Tivoli Hall, Kingstown, Dublin.

6048. **Improvements in the manufacture of flexible sheets for electrical insulation.** Carl Bollé, 57, Barton-arcade, Manchester. (Charles W. Jefferson, United States.)

6075. **Improvements in electric switches.** William James Davy, 40, Chancery-lane, London.

6084. **Improvements in electrical railway signalling and apparatus therefor.** Jules Ernest Florea, Viktor Takács, and Emerich Rittinger, 31, High Holborn, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1893.

6565 **Dry voltaic cells, etc.** Siemens Bros. and Co., Limited and Obach. (Second edition.)

1894.

5001. **Electric fuses and switches.** Essinger and Harden.

7711 **Element-board for electro-therapeutic diagnosis.** Bishop.

8238. **Electro-medical apparatus.** Clerke.

8240. **Ceiling rose for electric lamps.** Ball and Winter.

8480. **Galvanic batteries.** Rushton.

17525. **Laying electric conductors.** Jeckell.

21323. **Welding electrically.** Thompson. (Coffin.)

23944. **Electric rail and tram vehicles.** Diatto.

NOTES.

Price List.—The Indestructible Ignition Tube Syndicate, Limited, of 100c, Queen Victoria-street, E.C., have sent us a copy of their price list of incandescent and arc lamps and dynamos.

Bell Telephone Company.—The directors of the Bell Telephone Company have issued their balance-sheet for the year showing net profits, after deducting all expenses, amounting to £279,865.

Birthday Celebration.—Electrical illumination has this week played a prominent part in various German cities on the occasion of the celebration of the eightieth anniversary of Prince Bismarck's birthday.

Lecture.—Lord Kelvin last week lectured before the members of the Philosophical Society of Glasgow in the natural philosophy classroom of the university on the electrification of air and the thermal conductivity of rocks.

A Good Dividend.—The directors of the Aktien-Gesellschaft Mix and Genest will propose at the annual meeting early next month the declaration of a dividend of 11 per cent. for 1894 as compared with 8 per cent. in the previous year.

Municipal Telephony.—The Lord Provost's Committee of Edinburgh Town Council have resolved to recommend the Council to apply to the Postmaster-General for a license to establish a system of telephonic communication within the city.

New French Cable.—A Bill has been introduced by MM. de Mahy and Brunet in the Chamber of Deputies with a view to the establishment of a submarine cable between Tamatave, la Réunion, and Mauritius. The proposal has been referred to the Budget Commission.

Institution of Civil Engineers.—This institution still continues to increase in numbers, although not at the same rate as in former years. The list corrected to 1st inst. shows that there are now on the books 6,737 members of all classes against 6,557 in the corresponding period of 1894.

Northern Society of Electrical Engineers.—A paper by Mr. M. Holroyd Smith, entitled "Some Methods of Gathering the Energy in Electric Railways and Tramways," will be read at a meeting of this society, to be held on Monday next, 8th inst., at the Palatine Hotel, Hunt's Bank, Manchester.

City and South London Railway. — The Bill extending for a period of three years the time for the completion of the City and South London Railway has passed through its committee stage without opposition before the Chairman of Ways and Means. In the House of Commons on Monday this Bill was considered and ordered for third reading.

Royal Institution.—Lord Rayleigh will deliver the Friday (this) evening discourse at the Royal Institution. His subject will be "Argon." There will be no evening meetings on April 12 and 19, but the discourses will be resumed on April 26, when Dr. John Hopkinson will deliver a lecture on "The Effects of Electric Currents in Iron on its Magnetisation."

Utilising the Rhone.—The Société Lyonnaise des Forces Motrices du Rhône, who intend to utilise on a large scale the water power of the Rhone in connection with electric light and power work, have now commenced the organisation of their staff. M. Desarces, formerly with the Continental Edison Company in Paris, has already joined the Lyons company.

Tramcar Accident.—A telegram from New York on Monday stated that at Hazelton, Pennsylvania, an electric tramcar was descending a steep grade when the driver lost control. The engine and carriage dashed to the bottom, left the rails, and were completely wrecked. Three passengers were killed, two others sustained injuries, and about a dozen others were seriously injured.

Electric Call System.—The electric call system which is being established in Brighton as a development of the work of the post office has met with a gratifying degree of recognition; and, having regard to the initial difficulties which have to be overcome in opening up connections with the various districts of the town, the undertaking, under the direction of the postmaster, Mr. A. Wilson Hetherington, is gradually, but steadily, making headway.

Mitchell's Newspaper Press Directory. — The utter uselessness of such a directory as this may be understood if we say that the editor has not yet found out that the *Electrical Engineer* has for going on eight years been published as a weekly. Nor has he found out that such papers as *Lightning* and *Electricity* exist in any shape. Such a directory as this is on a par with a technical directory which purports to give a list of technical papers, and quietly leaves out of that list the rival it fears the most. The latter is a characteristic trait of human nature.

Switch for Damp Rooms.—The difficulty experienced in maintaining the insulation of switches in damp rooms is claimed to be overcome by the insulating switch which has been introduced by Mr. Adolf Schuch, of Worms-on-the-Rhine. It is a lever switch arranged on an earthenware insulator, the contacts being inside the latter. In case of any part of the switch becoming oxidised, it can be easily removed and another substituted at slight expense. The switch is specially intended for use in breweries and places where the operation of fermentation is carried on, and for mining purposes.

Inventors' Protection Society.—We are glad to learn from the *Elektrotechnischer Anzeiger* that a society has been formed in Berlin, under the title of the Deutscher Erfinderverein, for the purpose of protecting inventors from being duped by unscrupulous exploiters. The society, which already numbers a hundred members, undertakes to promote and obtain patents only for those inventions which are new and come out satisfactorily after being tested. The society, which is intended for the mutual protection of business men and manufacturers, will publish an official organ, and if it can accomplish what it proposes to do it should prove of great utility.

The Pacific Cable Question.—At the annual meeting of the Amalgamated Chambers of Commerce, which was held in London last month, the chairman, Sir Albert K. Rollit, D.C.L., M.P., addressed the meeting in advocacy of the British Pacific cable, and on noticing the presence of the Postmaster-General at the meeting strongly commended this subject to his consideration. In reply, Mr. Arnold Morley, M.P. (the Postmaster-General), expressed his sympathy with such extensions of telegraphic communication, and, while acknowledging the way in which the great cable companies carry on their work, took occasion to comment on the dissatisfaction occasionally expressed by the commercial world with respect to rates.

Novel Burglar Alarm.—A French contemporary states that the Administration Communale of Brussels have just resorted to electricity for annoying the light-footed gentry who burgle houses. It appears that in the offices of the first division of police has been fixed an electrical alarm, to which inhabitants can have their houses electrically connected on payment of a small subscription. Thus,

Digitized by Google

on a burglar making his entry into a dwelling protected in this manner, warning is given of the fact at the police station by the ringing of a bell and the dropping on the indicating board of a number corresponding to that of the subscriber. As a result, the police proceed to the premises indicated and arrest the burglars at once—if they have not already departed, which is very likely.

Electric Fusion of Metals.—A Swiss paper states that Mr. Nicolai Slavianoff, a Russian engineer, has devised a method of welding metals similar to that of Benardos, and which can be with advantage be substituted for the latter when repairs to pieces of metal are necessary. According to Mr. Lohmann, of the firm of Messrs. Pintsch, Berlin, the working of the system is as follows: The object to be dealt with is connected to one of the poles of the source of electricity, and the metal bar to be used in effecting the repairs is connected to the other pole. The two electrodes are approached so as to cause an arc to occur. The metal bar soon begins to melt, and the liquid metal is allowed to fall upon the parts to be repaired. The electrodes are, of course, gradually moved towards each other as the bar is fused, so as to obtain an uninterrupted arc.

Metric System of Weights and Measures.—The Select Committee of the House of Commons appointed to consider the advisability of adopting the metric system of weights and measures on Tuesday resumed the hearing of evidence. Captain H. R. Sankey, R.E., of Messrs. Willans and Robinson, said that the metric system of measurement had been adopted by his firm for the last two years. The reason of the change was the advantage of working interchangeably with manufacturing engineers on the Continent. His firm's trade was mainly British, but no objection had been made to metrical measurements by British customers. The workmen were agreed that the millimetre was much more easy to work to than the English measure, and it was much less liable to error. The inconvenience of the change to the metric system was only felt by the workmen for a few days.

Lighting at Southampton.—It will be seen from the accounts of the Southampton Electric Light and Power Company which are given in another column, that there is a slight increase in the works' costs of ·07 per unit, notwithstanding the increased output. This is partly due to the fact that the company have had to pay on an average 3s. per ton more for coal than in 1893, and also because they have had since February, 1894, to supply at any hour of the day or night from mains distinct from their lighting mains two electric cranes which require a 100-i.h.p. engine and dynamo to be specially reserved for them. The point is more clear when it is stated that on the lighting the company sold 550 units per i.h.p., and on the crane work only 88 per i.h.p. The increase in management is due to the fact that in 1893 the directors took no fees. During the year the company have added a Willans-Crompton set of 100 i.h.p. and a Babcock and Wilcox boiler capable of evaporating 5,000lb. of water per hour from and at 212deg. F.

Rope versus Belt Driving.—The committee of Génie Civil de la Société Industrielle du Nord de la France are endeavouring to complete their experiments commenced last year in regard to the relative merits of rope and belt driving. For this purpose, M. Dubreuil, the president of the committee, has addressed a series of questions to the French Society of Civil Engineers. The tests hitherto made by the committee were with a 200-h.p. engine actuating alternately by ropes and belt a generator having a total output for supplying 2,000 incandescent lamps. The questions upon which information is now desired to complete the experiments are as follow: (1) method of driving from the steam-engine, by ropes or belt; (2) power transmitted, number and diameter of ropes, or kind of belt and thickness and width thereof; (3) distance between the shafts, diameter of flywheel, and speed and diameter of the pulley driven; (4) date of laying down ropes or belt, and price, including putting up; (5) approximate annual cost of maintenance and duration of running; (6) nature of the industry carried on; (7) personal opinion on the choice of the installation; (8) nature, number, and cause of any accidents.

Municipalisation of Tramways.—It is stated that in case the London County Council decide to proceed with their Bill to place and run carriages on any tramway which has been or may be purchased, the companies intend to offer a vigorous opposition to the passing of the measure. The latter, in their petitions, point out that the Bill as framed would enable the Council to use not only existing tramways, but any tramway which may be constructed in the future, and they contend that to sanction such wide powers is contrary to all parliamentary precedent and to the Tramways Act of 1870. Moreover, the Standing Orders of Parliament expressly prohibit the granting of such powers. These orders, they say, were revised within the last few years, and only permit local authorities to work tramways under special circumstances and subject to special conditions. None of the special circumstances exist, they assert, in the case of London, and as large sums of money have been embarked in tramway undertakings, they submit that it would be unjust to the many persons who have invested their money that the prohibitions of the 1870 Act and the Standing Orders should now be over-ridden. On general grounds they submit it would be unfair to allow the Council to enter into competition with them out of the moneys raised by the rates.

Electric Lighting in India.—A special feature of the investiture durbar at Government House in Calcutta recently was the electric lighting. According to the *Indian Engineer*, the large durbar shamiana was lighted by incandescent lamps of various sizes. In the compound, six 2,000-c.p. arc lamps were erected on wrought-iron standards. These lamps were run in pairs working on the 110-volt circuit used on the incandescent lighting and were absolutely steady. They were of the Crompton-Pochin type. The generating plant consisted of a 12-h.p. portable engine fitted with two flywheels, to which were belted two Crompton dynamos. The contract was entrusted to Messrs. Kilburn and Co., Calcutta, the local agents of Messrs. Crompton and Co., of Messrs. Richard Hornsby and Sons and Henley's Telegraph Works Company. It is stated that the excessive moisture of the soil in which the cables which convey the current from the Calcutta station to the lamps from the station at Halliday-street are laid has caused them considerable injury, and their immediate renewal is deemed to be absolutely necessary. The Municipal Commissioners have in consequence invited tenders from specialists for both underground and overhead cables, the tenderers to state the number of years for which they guarantee the proper working of the cables.

Electric Power in Sawmills.—An interesting installation of the electrical transmission of power has been carried out at the works of MM. Dietrich and Co., of Lunéville. The problem to be solved, according to *L'Electricien* of March 23, was to operate by electric motors the machine tools in a sawmill 200 metres distant from the generating dynamo; a 5-h.p. pump on the banks of the Meurthe, some 700 metres from the source of power; and a 21-h.p. ventilator arranged near the generating station. The dynamo is of the Pieper type, giving 425 amperes at 125 volts when driven at 630 revolutions a minute. As

Digitized by Google

the load on the generator was expected to greatly vary (from 150 to 425 amperes), a compound-wound dynamo has been put down so as to maintain a constant pressure at all loads. The current is taken to a main switchboard from which three circuits are led to the sawmill, pump, and ventilator respectively. A distributing board, to which each motor is separately connected, is arranged in the sawmill, which contains three motors of from 10 h.p. to 12 h.p. each which actuate saws. The ventilator, which supplies air under pressure to a number of forges, is driven direct by a 22-h.p. motor. The working of the electric pump is controlled from the generating station, close to which is situated a reservoir supplied by the pump. Originally when steam power was employed the annual cost of working, including coal, attendance, maintenance, and lubrication, amounted to £180, whereas now it is only £23.

History Repeats Itself.—Whether comparatively new or very old, history repeats itself. When the promoters of the Paddington - South Kensington - Victoria Railway desired to construct this line, they were debarred from doing so by reason of the objections raised against the use of powerful electric currents in the neighbourhood of the scientific institutions at South Kensington, it being feared that the exceedingly sensitive instruments therein used would be injuriously affected. A similar state of affairs has arisen in Berlin, or at all events in ancient Charlottenburg, which, together with Munich, may be likened unto South Kensington or the Board of Trade laboratory. For word has gone forth that the Berlin-Charlottenburg Tramway Company intend to substitute electric for horse traction. But the Physikalisch-Technische Reichsanstalt object to the introduction of electric traction on that line. Although the home of the Anstalt in the Marchstrasse is some 250 metres distant from the point where the proposed tramway circuits would be installed, yet the authorities of the institute consider that the delicate instruments used in the Anstalt for standardising purposes would be seriously affected by the working of the projected electric tramway. But the most remarkable thing is the fact that, notwithstanding the objections of the Reichsanstalt, the Technische Hochschule, which all Berliners and metropolitan seekers know so well, has not raised its voice against the scheme, although it is situated in the immediate neighbourhood of the route proposed to be followed by the tramway.

The Pennsylvania Railway and Electric Traction.—The Pennsylvania Railway intends to equip its Mount Holly branch, 12 miles in length, with electric cars on the overhead trolley system. It is now understood, the New York *Electrical Review* states, that this equipment will be in the nature of an experiment which will have an important bearing on a longer branch of the same railway. It is reported that the Pennsylvania Railway has closed a contract with the General Electric Company for three sets of experimental apparatus of different sizes and styles to be used on the Mount Holly branch. The experimental car equipment will consist of one set comprising four 25-h.p. motors, one set consisting of one 75-h.p. motor and one set consisting of two 74-h.p. motors, each set to be placed under 40ft. passenger coaches, rather lighter in construction than those generally used on steam roads, and which will eventually be developed into a standard electric passenger coach by the Pennsylvania Railway. The result of the experiments on the Mount Holly branch will determine whether or not the Camden and Atlantic branch of the Pennsylvania Railway will be similarly equipped. This branch is about 59 miles long, extending from Philadelphia to Atlantic City, and it is one of the oldest steam railways in America. Granted that the Mount Holly experiments are a success, it is proposed to similarly equip the Camden and Atlantic road with a centre-pole trolley construction. The purpose is to run trains on 10 minutes' headway on schedule time of two hours for the 59-mile trip. The fare for the round trip will be placed at 1dol., and it is believed that the road, when electrically equipped, will do a very large excursion business.

The Madagascar Cable.—Telegrams from Madagascar inform us that the cable between Mozambique and Majunga has been laid. From the continental Press we gather that this cable, which may be called a "war cable," was manufactured by a combination of two French firms. The price agreed on for the cable when laid is given as £84,000, whereas an English company offered to do this work for £50,000. Doubtless the French Government prefer to pay the higher price with a view to affording experience in the manufacturing and laying of submarine cables to the firms who have taken up that industry in France. Of course the amount in excess of a reasonable profit may be looked on as a subsidy to the contractors. The following is translated from *Le Temps* of Wednesday: "We were able to announce in the *Petit Temps* of last night that telegraphic communication with Madagascar is established, uniting Majunga with the station of Mozambique. This pleasing intelligence will be well received, not only by all those who think that it is in the national interest to withdraw our foreign communications from the control of English companies, but above all by the families of our brave soldiers, who will appreciate this link. This accomplishment will prove to all doubters that our manufacturers are quite equal to their foreign rivals. We may also, perhaps, add that probably this result would not have been so quickly attained if we had employed English contractors—an unfortunate habit which we have hitherto had. On a recent occasion Sir John Pender, the chairman of a submarine cable company, spoke with some scorn of French manufacturers, who were, according to him, incapable of bringing this enterprise to a successful issue. Facts, however, have just given him the flattest of contradictions (*le plus éclatant démenti*)."

Electric Towing on the Bourgogne Canal.—Some further particulars have been published by M. Gaillot, engineer of the Ponts et Chaussées, in the *Annales* of that Department, concerning the system of electric towing adopted on the Bourgogne canal. The motive power is furnished by turbines arranged at Pouilly on the side of the first sluice of the contributary to the Canal de Bourgogne and at Escommes, in the neighbourhood of the first sluice of the Saône. The turbines, which run at 100 revolutions a minute, drive a horizontal shaft, from which the dynamos are driven. The current is transmitted to a three-wire system, 8mm. in diameter, carried on posts and by means of cross wires. The current is collected by means of a trolley, the long pole (24ft.) of which is arranged on the towing boat. This length of the trolley pole has been necessitated by the oscillation of the boat. The motor carried on the towing boat is of the Gramme type, connected by belt to a pulley driving the gear which actuates the pulley operating upon the chain. The towing boat is 50ft. long, 10ft. 8in. in width, and the draught is 1ft. 6in. A battery of 250 accumulator cells has also been installed at Pouilly. The battery is placed in shunt with the line, and is operated simultaneously with the generators. The towing installation has cost 135,000f. (£5,400), but this is reduced to 120,000f. (£4,800) when the accumulators, the use of which is considered hardly justified, are left out of consideration. From September 1, 1893, to April 1 following 81,000 tons were transported in 897 hours at the price of 5,900f. (£236). During the same period of

Digitized by Google

the previous year 78,600 tons were hauled in 917 hours at the price of 8,000f. (£320). It is concluded from this that 1,000 tons require with steam 11·65 hours and cost 102f., and with electricity 11·01 hours at an expenditure of 70f.

Flexible Couplings.—It appears that more consideration is now being given to the use of flexible couplings for connecting power shafts. Some time ago we referred to the use of Snyers clutches at the Worcester electricity works, this being followed by a description of the employment of the same form of clutch at a small central station in France for connecting together gas-driven alternators. Since then a discussion has arisen in a French contemporary as to the merits and demerits of flexible couplings, and now a German firm (Messrs. G. Luther, of Brunswick) have brought out a clutch which very much resembles that of Snyers. It is formed of two discs, one carrying steel brushes and the other steel combs, the former being caused to engage with the latter on coupling up. The dimensions and weights of the various couplings made by the firm are as follow:

H.P. at 100 revolutions.	Dimensions in millimetres.			Weight of coupling in kilogrammes.
	A.	B.	C.	
4	420	310	340	80
8	460	340	375	132
14	500	380	420	198
25	550	415	455	275
35	585	435	480	390
54	610	460	505	520
70	645	480	530	670
95	710	530	585	830
118	750	570	630	1,000
155	770	590	650	1,240
200	840	645	710	1,500
270	950	740	815	2,200
350	1,085	860	945	3,150
460	1,215	975	1,075	4,300

As in the case of the Snyers clutches, the coupling in question is particularly suitable for connecting a loose pulley driven by both a steam-engine and turbine, or by either.

Electric Traction at Leipsic.—The shareholders of the Leipsic Tramways Company met on Monday at 39, Lombard-street, E.C., to consider a proposal for the sale of the undertaking to a German company. The Chairman (Mr. W. B. Hawkins) explained that there was a strong idea among the authorities at Leipsic that the seat of the company should be at that place, and that in view of the desirability of working the system by electricity, he thought this company would find some serious difficulty in the future if it remained in English hands. He thought the offer which had been made them was a liberal one, and one which they should readily accept—namely, £450,000—which represented about £15 for their £10 shares. The amount was payable as to about £15,000 in cash, and the remainder in cash or bonds carrying 4 per cent., at the option of the purchasers. He concluded by moving a resolution approving the principle of the proposed transfer, explaining that meetings for the formal winding up of the company and appointment of a liquidator would have to be held hereafter, if the present resolutions were passed. Mr. A. G. Kendal seconded the motion, which was carried unanimously. In this connection a Leipsic paper states that the negotiations between the Gesellschaft für Elektrische Unternehmungen and the management of the Leipziger Pferdebahn Gesellschaft have now been brought to a close. Subject to the consent of the before-mentioned meeting, and to that of the Council of the town of Leipsic, the tramway passes by purchase into the possession of the Gesellschaft für Elektrische Unternehmungen for the introduction of electric traction. In accordance with the conditions laid down by the Town Council, the latter company will form an independent company to carry on the electric tramway, with its seat in Leipsic. The transfer of the undertaking will probably take place in January next. It will be evident that the only point yet to be decided is to gain the consent of the Leipsic Town Council, and that may be taken for granted.

Heat Imparted by the Electric Light.—A French contemporary, the *Moniteur Industriel*, states that Captain Exler, of the Austrian army, has found that a 16-c.p. incandescent lamp gives off a maximum temperature of 94deg. C., and a lamp of 25 c.p. 101deg. C. Two lamps placed in a wooden receptacle yielded a temperature of 215deg. C., decomposing explosives such as gunpowder, ecrasite, pyroxyline, etc., but without exploding them. The receptacle having been filled with water, the latter became in a state of ebullition at the end of 15 minutes. In case of the breakage of the lamps, the powder and pyroxyline do not ignite, but this is not the case if an explosive gaseous mixture is present. The captain points out that too many precautions cannot be taken, notwithstanding the use of electric lamps, which, whilst reducing the danger of an explosion, do not completely remove that danger. From the experiments made, it is held that the solution of the problem does not in any way lie in the employment of a double bulb with an intermediate closed space filled with air or water. The heating of the water would be avoided by the use of a reservoir having double communication with the external envelope, an arrangement by which would be established a continuous current, and which would allow of the cooling of the water. But in order that the latter may be sufficient, the volume of water necessary would render the arrangement heavy and cumbersome, and the method is consequently not practical. A rational solution for the lighting of places where gas or explosive materials are present seems to be, according to the captain, simply in arranging the incandescent lamp in a glass cylinder closed at both ends by means of metallic cloth; the current of air would freshen the bulb, and the slight heating of the air passing out would not be detrimental. In case of the breakage of the bulb, the combustion of the filament would produce at most only a small internal explosion, as in miners' lamps, incapable of transmitting fire outside.

Telephonic Communication with Lightships.—Prof. Lucien I. Blake, in a report recently submitted to the Government, describes the method employed by him to telephonically connect the Scotland lightship with the shore at Sandy Hook. Before the experiments at the Hook took place, Prof. Blake succeeded in establishing communication between a lightship and the shore at Wood's Holl, Mass., by a method in which the telephone cable is fastened to the anchor chain. This worked well until the lightship dragged her anchor during a gale and snapped the cable. The New York *Electrical Engineer* states that in the experiments at Sandy Hook, however, new conditions presented themselves and the Wood's Holl system would not answer, so another arrangement was adopted and found satisfactory. Instead of the telephone cable passing through the fluke of the lightship anchor, and communicating, as in the other case, through the anchor chain with the vessel, the cable is to run to a spot near the lightship's anchor, within the field of the ship's circular swinging with the wind and tide, and this field itself is electrified. Another and smaller cable is attached to the end of the first cable, and runs at right angles to it in both directions. From this new cable, again, other still

Digitized by Google

smaller cables run parallel to the first. In this way the field through which the lightship moves in her movements around her anchor is thoroughly and equally electrified. The Light-house Board has proposed to connect two such stations much further apart, where the conditions of the bottom, currents, and approaches are different. The places mentioned for these experiments were the Assateague Lighthouse, Virginia, to the Winter Quarter Shoal Lightship, distant 11 miles, and from the Cape Fear Lighthouse, North Carolina, to the Frying-Pan Shoals Lightship, distant 18 miles. The most important recommendation in this respect, however, is to lay a cable from Sankaty Head Lighthouse, on the island of Nantucket, Massachusetts, to the Nantucket New South Shoal Lightship, 30 miles south. This lightship is the most distant from the coast of any in the service, and is in the track of all coasting vessels going outside of Nantucket from north to south, and of vessels going to and from Europe.

Utilisation of Water Power.—The differences in level of many watercourses have from time immemorial been employed for the production of motive power, but it is only in recent years that the idea of utilising high falls has been practically carried out. One of these cases, which is to be found at Chapareillan, in the Isère Department, is described by *L'Industrie Electrique* of March 25. The Chapareillan fall, which is being exploited by the Société Générale d'Electricité, of Lyons, is produced by the stream Le Cernon, which descends from the Granier mountain in the Chartreuse group. The water is collected in a reservoir at a height of 1,062 metres. From here the water is led by means of a conduit 3,200 metres in length to the works, which are situated near the village of Chapareillan, at an altitude of 450 metres. At its upper part, and for a distance of about 2,000 metres, this conduit has an internal diameter of 350mm. (14in.); in the lower part the diameter is reduced to 30cm. (12in.). The thickness in the former case is only 4mm.; as it approaches the works it reaches 12mm., and its lineal weight then exceeds 140 kilogrammes per metre. The conduit has been constructed to deliver, when the works are in full operation and at the times of greatest consumption, 200 litres of water per second. The power obtained will be 1,000 h.p. when calculating upon an efficiency at the turbines of 70 per cent. It is intended to utilise this 1,000 h.p. by means of seven turbines, each of 185 h.p. running at 360 revolutions a minute. One of the turbines will be kept as reserve. The first turbine erected has been made by MM. Brenier and Neyret, of Grenoble. Each turbine will be coupled to a self-exciting alternator of the Zipernowsky type made by the Creusot Works. Two of these alternators are already in position, and the others are in course of construction. At full load they will each produce 25 amperes at 5,400 volts. The current will then be transmitted within a radius of 18½ miles. It will then be stepped down to 120 volts for distribution to consumers. The inauguration of the Chapareillan works will take place next month as far as Challes-les-Eaux. The advantages of utilising high falls, our contemporary points out, are of two kinds. In the first place, the high-pressure turbines indirectly produce an absolutely fixed light without the necessity of using regulators. In the second, and on account of the small discharge necessary to obtain a considerable power, these falls allow of supplying a considerable number of lamps relatively to the constant power at one's disposal. In fact, statistics show that in electrical installations combined for the transmission of motive power during the day and the energising of lamps, the average of the daily consumption does not exceed eight hours. If, then, at the source of water supply a reservoir is constructed capable of containing two-thirds of the delivery of the stream during 24 hours, we shall be able to supply a number of lamps three times greater than the normal discharge of the same stream would permit. That is the reason, our contemporary concludes, for the construction of the Chapareillan reservoir, which has a capacity of 3,000 cubic metres.

The Heilmann Electric Locomotive.—In a paper recently contributed to the American Institute of Electrical Engineers, Mr. Ward Leonard says of this locomotive: "In France I examined what I considered the most important electrical engineering development of all that I saw. It was the Heilmann electric locomotive. Having been for some years past a firm believer in the merit of this machine, and having been in correspondence with Mr. Brown, Mr. Heilmann's electrical engineer, as to an invention of mine used in this locomotive for the first time on a large scale, I was especially interested in it, and my hearers will please discount as they may think necessary my description of the advantages of a locomotive using my system of control. The locomotive I saw was the first one built, and was not in service when I was there. It had run 2,200 miles commercially, however, and as a result of the performance of this first locomotive, which was 600 h.p., they are now building two locomotives of 1,500 h.p. each, which it is expected will go into commercial service about June next. This electric locomotive carries its own central station with it. It is really a complete central station on wheels, with its power used for propelling itself. The entire weight of the locomotive is 114 long tons—that is, about 15,500lb. per driving wheel, which is about the same as our standard practice in this country. With a tractive coefficient of ·2 this means a draw-bar pull of 50,000lb., and, assuming friction at 6lb. per ton, we find that 50,000lb. draw-bar pull would enable us to pull 1,900 tons on a 1 per cent. grade at a low speed, say 15 miles per hour, and would give us ample draw-bar pull for handling a 200-ton train at any speed thus far seriously discussed. Most engineers who have heard of the Heilmann locomotive have derisively dismissed it from their minds as a ridiculous monstrosity of a crazy Frenchman, but I have for some time believed, and am now convinced, that you will in the immediate future be bound to give this machine the most respectful consideration. Under the electrical arrangement on this locomotive, the electric energy is used in such a manner that its voltage is varied in proportion to the speed desired, and the amperes are in proportion to the torque required, so that the electrical energy produced is utilised in the most efficient manner possible. An electric locomotive of this kind would probably cost for the first few about 30,000dol., each being equipped with a 1,500-h.p. boiler of our best marine type, and one of our best automatic cut-off compound engines directly coupled to a modern multipolar generator. I believe that a locomotive of this type could be built which would be able to pull 50 per cent. more weight than any of the present steam locomotives, and it could pull the same weight at 50 per cent. higher speed. I think this type of electric locomotive is the stepping stone between the steam locomotive and the electric locomotive operated from a distant central station. To properly try the experiment of operating a high-speed locomotive of 1,500 h.p. from a central station would undoubtedly cost nearly a million dollars. To try it with a locomotive of the Heilmann type would cost not more than 50,000dol., and if it proved successful, it is not much of a step to replace the boiler and constant-speed steam-engine with the moving contact and constant-speed electric motor for driving the generator already tested and proved satisfactory."

THE THEORY OF ALTERNATING CURRENTS.—II.

BY A.INST.E.E.

§ 5. **Calculation of Inductance.**—Having considered inductance as a physical phenomenon accompanying varying currents, we shall now treat it quantitatively, and from the nature of alternating currents, pulsating alternately in positive and negative directions at a rapid rate, it is evident that the back pressure of self-induction is an important factor in all calculations dealing with alternating currents. As already mentioned, the coefficient of self-induction is a constant quantity, depending on the size and geometrical form of a circuit, and since alternators, transformers, and other appliances forming part of such circuits contain one or more helices, we shall first show how to determine the magnitude of this constant for a simple electromagnet. From the explanation and definition given, it is obvious that the problem is simply to determine the number of linkages per second due to unit current. In the first place, we must know how to calculate the magnetic flux set up in the coil by unit current passing through it. Any good text-book proves the rule for determining the flux, so that we shall here only state it. The intensity, H, of a magnetic field at the centre and inside a hollow solenoid or helix, through which a current, C (absolute units), is passing, is given by the equation

$$H = \frac{4\pi C n}{l},$$

where n = number of turns of wire, l = length in centimetres, and H = number of lines of force per square centimetre passing through the coil. To get the total number of lines of induction through the coil we must multiply H by the area, A, of cross-section of the coil—that is, the magnetic flux is $H \times A = \frac{4\pi C n A}{l}$ C.G.S. units. For unit current passing the flux is, therefore, $4\pi n A/l$, and these link themselves with each of the n turns, therefore the coefficient of self-induction, L, of the coil is $\frac{4\pi n A}{l} \times n$, or $4\pi n^2 A/l$. As this is expressed in absolute units, we must divide by 10^9 to reduce it to henrys. If the radius, r, of cross-section of the coil is given instead of the area, the above expression becomes $L = \frac{4\pi n^2 (\pi r^2)}{l \times 10^9} = 4\pi^2 n^2 r^2/l \times 10^9$, since $A = \pi r^2$. So far no notice has been taken of the iron core. The above expressions refer only to hollow coils. The presence of iron materially increases the lines of induction, and so increases the value of L, and if we assume that the iron core is not magnetised beyond 5,000 or 6,000 lines per square centimetre, we shall be approximately correct in assuming that the value of L is increased μ times, where μ is the permeability of the iron for the current used. The induction through the coil is denoted by the letter B, so that $B = \mu H$; consequently, $L = \frac{\mu \cdot 4\pi n^2 A}{l \times 10^9} = 4\pi^2 n^2 r^2 \mu / l \times 10^9$ henrys.

Let us now consider a numerical example. Calculate the coefficient of self-induction of a solenoid of 500 turns of uniformly wound wire, the mean radius of the coil being 2·8cm., and the length of the solenoid 22cm.

Since $L = 4\pi^2 n^2 r^2/l \times 10^9$ henrys, we get by substitution

$$L = \frac{4 \times 22 \times 22 \times 500 \times 500 \times 2{\cdot}8 \times 2{\cdot}8}{7 \times 7 \times 22 \times 10^9}$$

$$= 0{\cdot}00352 \text{ henry.}$$

If the helix be completely filled with iron, the permeability of which is 800, $L = 0{\cdot}00352 \times 800 = 2{\cdot}816$ henrys. This may be taken as a fair average of the value of the inductance of a relay of 100 ohms resistance, and will give us an idea of the retarding effect of self-induction in signalling appliances.

§ 6. **Time Constant.**—The consequence of this inductance of the above electromagnet is to retard the growth of the current just at starting, so that a short interval of time, t, must elapse before the current becomes a maximum, and Helmholtz has proved that the strength of the current C_t after a time t has elapsed, is given by the following equation, known as "Helmholtz's Equation":

$$C_t = \frac{E}{R}\left(1 - \epsilon^{-\frac{R}{L}t}\right),$$

where $\epsilon = 2{\cdot}7183$, the base of the natural logarithms.

By writing the equation thus: $C_t = \frac{E}{R} - \frac{E}{R} \times \epsilon^{-\frac{R}{L}t}$, or $C_t = C - C \times \epsilon^{-\frac{R}{L}t}$, where C is the maximum current, it is obvious that C_t is less than C. A little consideration only is needed to show that if L is large compared with R, then $\epsilon^{-\frac{R}{L}t}$, which denotes the *retardation due to self-induction*—*i.e.*, the fraction of the maximum current not reached—has an appreciable effect on the time, t, which must elapse before the current becomes a maximum. On the other hand, if L is small compared with R, then the *retardation* is slight. These remarks indicate the influence of the quantity $\frac{L}{R}$, which we must consider fully; but before doing so we will give several values of C_t for different values of t, so that the student may get a clear insight into the meaning of Helmholtz's equation. The example taken is the electromagnet already considered, and if E is 10 volts, then, since R is 100 ohms and L = 2·816 henrys, the values of C_t for different values of t are as follows:

t in fractions of a second.	$1 - \epsilon^{-\frac{R}{L}t}$	C_t
0·01 or $\frac{1}{100}$ sec.	1 − ·7012 = 0·2988	0·02988
0·015	1 − ·5872 = 0·4128	0·04128
0·02	1 − ·4916 = 0·5084	0·05084
0·02816	1 − ·368 = 0·632	0·0632
0·03	1 − ·3448 = 0·6552	0·06552
0·05	1 − ·1698 = 0·8302	0·08302
0·075	1 − ·06975 = 0·93025	0·093025
0·08	1 − ·05976 = 0·94024	0·094024
0·1 or $\frac{1}{10}$ sec.	1 − ·0287 = 0·9713	0·09713

Now, if L were zero, the maximum steady current as given by Ohm's law, $C = \frac{E}{R}$, is $\frac{1}{10}$ or 0·1 ampere, and this value would be reached instantly, whereas, in consequence of the inductance of the circuit, we see from the above table that one-tenth of a second must elapse before 97 per cent. of its maximum value is reached. The rate of growth is shown very clearly in Fig. 2, in which O X is the time line, the fractions of a second being denoted by lengths, whilst the resulting values of C_t in the above table are given as ordinates, from which we get the curve O P Q R.

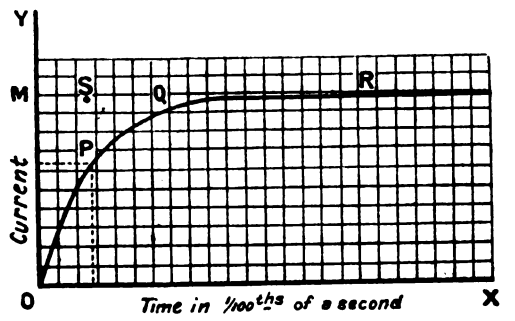

FIG. 2.

It will be noticed that the curve consists practically of three parts:

(1) O P, which is straight and nearly vertical;
(2) P Q, which is curved and forms the bend of the curve; and
(3) Q R, which is straight and practically horizontal.

The first part, O P, depicts the growth of the current during the time that energy is being spent in overcoming the back pressure, during which time the inductance, L predominates; this is gradually overcome, and then only the resistance, R, governs the rate of growth. Up to the point Q, the growth of the current depends upon the ratio of the inductance to the resistance—that is, upon the ratio L/R—which is termed the *time constant* of the circuit, and

Digitized by Google

is so called because it is equal to the time taken by the current to rise to a definite fraction of its maximum value. In fact, if L be given in henrys and R in ohms, the fraction L/R is in seconds—that is, $L/R = t$ seconds.

To determine what this definite fraction is, we have only to substitute, L/R for t in Helmholtz's equation, and find the value of C_t.

$$\text{Now } C_t = \frac{E}{R}\left(1 - \epsilon^{-\frac{R}{L}t}\right) = \frac{E}{R}\left(1 - \epsilon^{-\frac{R}{L}\times\frac{L}{R}}\right)$$

$$= \frac{E}{R}\left(1 - \epsilon^{-1}\right) = \frac{E}{R}\left(1 - \frac{1}{\epsilon}\right) = \frac{E}{R}\left(\frac{\epsilon - 1}{\epsilon}\right) = C \times \frac{\epsilon - 1}{\epsilon}.$$

The fraction is therefore $\frac{\epsilon - 1}{\epsilon}$, but $\epsilon = 2{\cdot}7183$, and substituting this value, $\frac{\epsilon - 1}{\epsilon} = \frac{2{\cdot}7183 - 1}{2{\cdot}7183} = 0{\cdot}632$.

Therefore $C_t = 0{\cdot}632$ C.

In the example considered above, and for which the curve is plotted, it will be seen that this value is reached at the point P after 0·02816 of a second has elapsed. In this case 0·02816 is the time constant, since $0{\cdot}02816 = \frac{L}{R} = \frac{2{\cdot}816 \text{ henrys}}{100 \text{ ohms.}}$. It should also be noted that the deficit from maximum current at this point is denoted by the length P S, which is equal to $\frac{E}{R} \times \epsilon^{-\frac{R}{L}t}$ when $t =$ 0·02816 of a second. In Fig. 2, O M denotes $\frac{1}{10}$ ampere, or $\frac{E}{R}$.

ELECTRIC MAINS IN PARIS.*

BY A. MONMERQUE.

The work on the electric mains in Paris followed the concessions given by the Municipal Council in December, 1888, and was actually commenced in March, 1889. At this date the three following undertakers only started laying their mains—viz., La Compagnie Continentale Edison, La Société d'Eclairage et de Force par l'Electricité, and M. Victor Popp. Since then other companies have commenced work, as below—La Société du Secteur de Clichy in October, 1890, and La Société du Secteur des Champs-Elysées in June, 1892. The mains of La Société du Secteur de la Rive Gauche are still in course of construction.

Only underground systems of mains are allowed by the authorities in Paris, and so the question of type alone remains for consideration.

It will be useful to note the experiences gained in the last five years, and to review the principal faults found during that time. The conclusions which the facts point to are the following, which seem now to be well established in spite of adverse opinions held in the past by some engineers.

1. When the electric conductors are placed in metallic envelopes for mechanical protection, it is necessary to take great care to prevent any chance contact between the copper conductor and the envelope. To ensure this it is necessary to use insulated cables, and to take similar precautions as are required when armoured cables are employed and laid direct in the ground.

2. The conduits used, specially with bare conductors, ought to be waterproof, and as this condition cannot always be assured, a good system of drainage should be provided.

3. There is reason to specify the materials allowable in the construction of the conduits, and in this direction to forbid the use of glazed earthenware.

4. Where insulated conductors are employed the method of supporting them in the conduits should receive special attention, to avoid mechanical injury to the insulation, and consequently a low insulation resistance.

These very simple conclusions are extracted easily from the results which we give as briefly as possible below.

* *L'Eclairage Electrique.*

One section of Paris was supplied at first by insulated cables laid in cast-iron pipes, Fig. 1. The conductors were drawn in these pipes after they were laid. At once a large number of faults developed. The insulation of the conductors was insufficient, and also was damaged during the drawing-in process. The metallic pipes were the means of readily earthing the conductors, and it became impossible to continue the supply. The society quickly condemned this, its own system, but they did not abandon the metallic envelope.

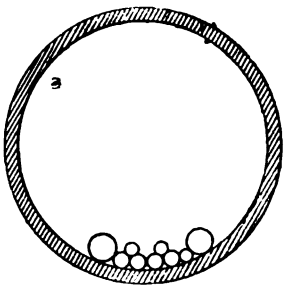

FIG. 1.—Insulated Main in Iron Pipe.

They employed a rectangular iron conduit, and endeavoured to ensure that no contact should ever be made between the copper and the iron conduit. To this end they had recourse to two different methods according to the pressure of the supply. For high-tension cables used to charge accumulators in series at 1,500 volts, they did not hesitate in adopting covered cables made to the following specification: a copper core insulated with one layer of pure rubber, two of vulcanised rubber, two of rubber tape, the whole covered with a lead sheath and a bituminous braiding. These cables were placed in chases of paraffined wood, as shown in Fig. 2. This system gives a double protection against contact between the copper and the iron conduit—*i.e.*, the insulation round the cable and the paraffined wood.

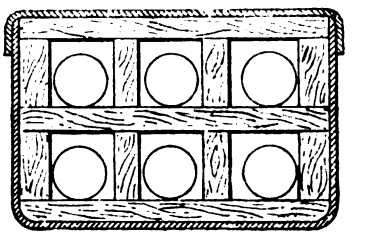

FIG. 2.—High-Tension Main in Paraffined-Wood Chases in Iron Conduit.

The conditions of the specification made the cable contractor responsible for the insulation resistance, and these mains have not given the trouble which has given rise to the faults which occurred with the first and third systems. Why, then, should this system not be generally used? It is cumbersome; again, it has the inconveniences of armoured cables, notably in the limitation in the density of the current without their safety. For 110-volt mains the above method was considered too costly, and it was decided to use bare conductors, and to prevent accidental contact with the iron conduit by paraffined blocks and porcelain insulators, shown in Fig. 3.

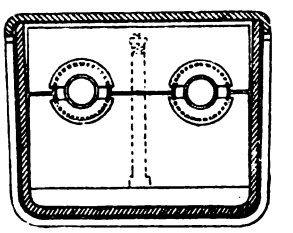

FIG. 3.—Bare Main in Iron Conduit. Section showing Insulating Supports.

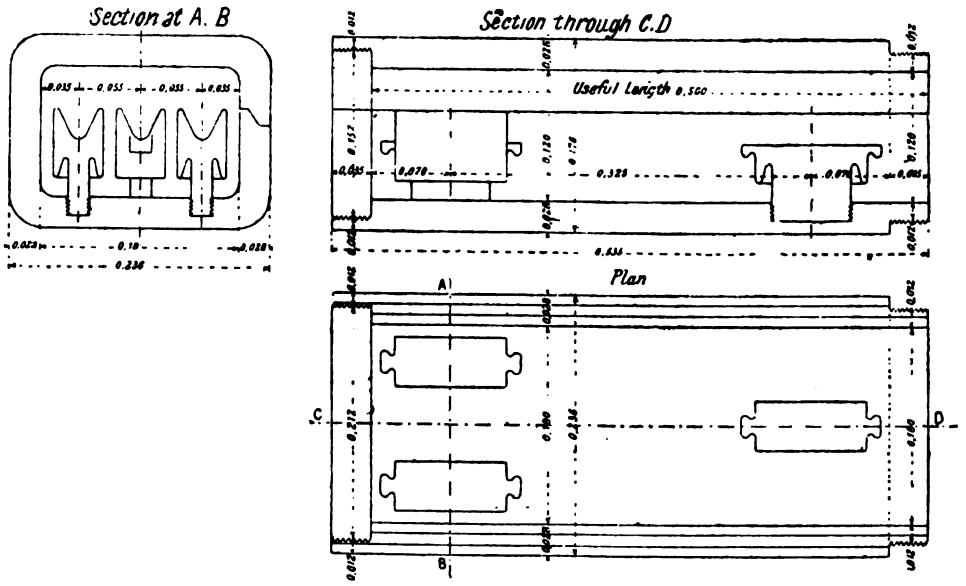
To guard against the chance of an accidental contact at a point between two supports, the space round the conductors was filled up with an insulating mixture of pitch and limestone. These materials were ground fine and used in the proportions of from 40 to 50 per cent. of pitch to 50 to 60 per cent. of limestone. The mixture was made on the spot, and run in hot till it completely filled the metallic conduit.

Digitized by Google

A short time after this system was started in regular use its defects resulted in bad accidents. Direct short-circuits were formed between the conductors and the conduit which are attributable to the following causes: The angles in the conduits were the seat of many faults, as at the bends the conductors did not keep their central position, but approached the iron sides, due to the displacement of the whole conduit from movements of the soil. The softening of the insulating packing whose melting point was too low also assisted this action. When the short-circuit once started, the pitch became completely liquefied and aggravated the fault.

As will be seen from the illustrations, the conductors are placed on porcelain insulators as when cement conduits are employed. In spite of these precautions, there have been serious faults. The company have, with a forethought and decision which is to be highly recommended, replaced all the pottery conduits regardless of the great expense caused by the change. They have used instead a cement concrete conduit of a smaller type, which can be adopted even in the most narrow streets. All their network now consists of the above conduits, and the results of careful work have resulted in the most satisfactory lighting of the section.



FIGS. 4, 5, AND 6.—Earthenware Conduit for Bare Mains.

The company, after this expensive experience, was obliged to acknowledge the faults of this system and to abandon these mains, which became an incessant source of danger under the public footpaths. The work of replacing them by armoured cables was carried out with method and rapidity by the new management of the company, who undertook the difficult task of remodelling and developing a very extensive network without stopping the lighting of the section. The execution of this very difficult work does honour to the engineers of the company, and the public safety was much benefited by these modifications in the system of mains.

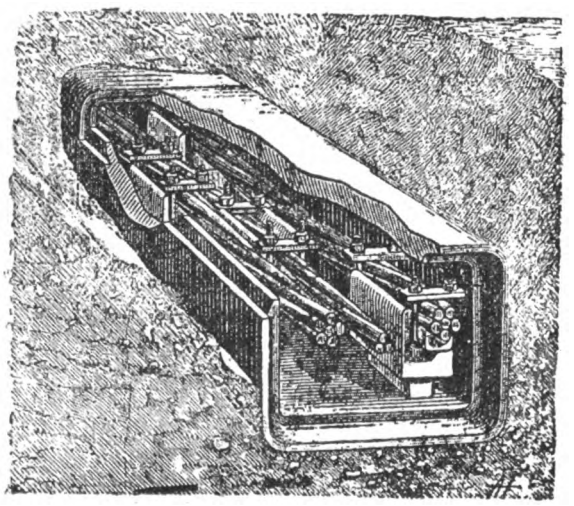


FIG. 7.—Earthenware Conduit.

One of the principal types of mains employed in Paris with bare conductors is the system of rectangular conduits made of concrete cement. One company, cramped by the use of this system in certain streets with narrow footpaths which had other mains under them, had recourse to the use of rectangular conduits of glazed earthenware, Figs. 4 to 7.

The phenomena which have been observed with earthenware conduits, and which have led to their being condemned, are very complex. Confining ourselves to the more important facts, after a certain length of time from the commencement of supply a quantity of whitish alkaline material was found in the conduits. The phenomenon continued, and, finally, the conduits were totally blocked by the material. On analysing the substance it was found to consist, not solely of alkaline carbonates, but also of pure sodium in sufficiently large fragments as to explode when thrown into water.

There are no means, as far as we know, of reproducing exactly the phenomenon in a laboratory, and many explanations have been given without it being possible to say which is correct. Some have attributed it to the sea salt used by the Parisian authorities for melting the snow. We doubt whether this method of clearing the snow is used at all on the footpath, but think it is reserved for roadways only, and even then the salt slush is swept away as soon as thawed and put down the sewers. A large quantity of Ourcq water is used in the operation, so that the quantity of salt on the footpath is soon diluted and quickly washed into the sewers. We cannot see, therefore, how this salt can penetrate under the footpath and get into the porcelain conduits. Others have blamed the cleaning of the shop fronts, but this explanation will not hold, as ordinary water is used for this purpose.

It is probable that the glaze of the earthenware, in the manufacture of which chloride of sodium is used, plays an important part in the production of this deposit. The conduits wherever they are laid are always humid, especially so in summer. The temperature of the air in them is below that of the outside air, and for this reason the moisture in the air condenses out the cold walls of the conduit. In winter, at any rate with bare cables the temperature of the air in the conduits is higher than that of the exterior air, and then the moisture does not condense as above.

It will be noticed that the joints in the conduit offer a comparatively easy access to water, and as we have stated, the subsoil of Paris is generally made ground, and hence is unstable and subject to frequent settlements. This leads one to conceive the possibility of water getting

Digitized by Google

into the conduit, and to the ensuing consequences, such as the decomposition of the water into explosive gases.

Whatever may be the explanations of the various accidents to which the earthenware conduits have given rise, it is useless to urge their retention for future use, but rather the necessity of their interdiction.

CONTINUOUS-CURRENT DYNAMO WITH A SINGLE BEARING.*

The type of machine illustrated is stated to be one to which the best geometrical proportions have been given to the armature and field magnets. This dynamo, which has just been brought out by the Cail Company, has been designed by M. Helmer, chief of their electrical department. In the machine illustrated, which is of 2,500 watts capacity, Fig. 1 is a longitudinal section, taken through the axle, and Fig. 2 is an end elevation. In machines of this type the yoke is a mass of metal, merely serving to connect the two sides magnetically; as there is only a single bearing, the axle must necessarily overhang. The dimensions of the bed-plate have been kept as small as possible, so that the machine only consists of those parts which are absolutely indispensable. By this means there is a considerable economy in the weight of the machine, as well as in the cost of fitting the bearings. One very important point in the construction of these machines has been the difficulty of securing to the bearing ample and automatic lubrication, and reducing the mechanical friction. Mr. Helmer has surmounted this difficulty by using a special bearing, shown in detail by Fig. 3. The special feature of these bearings is the length of the brasses, which are seven or eight times as long as the diameter of the shaft.

The oil is contained in a reservoir, R, into which plunges a ring, *b*, carried by the axle. A number of curved wings are set round this ring, and form small troughs, giving a much larger supply of oil than would be the case with a plain ring. The brass, *d*, is held by a screw, which prevents it from turning or from having lateral play.

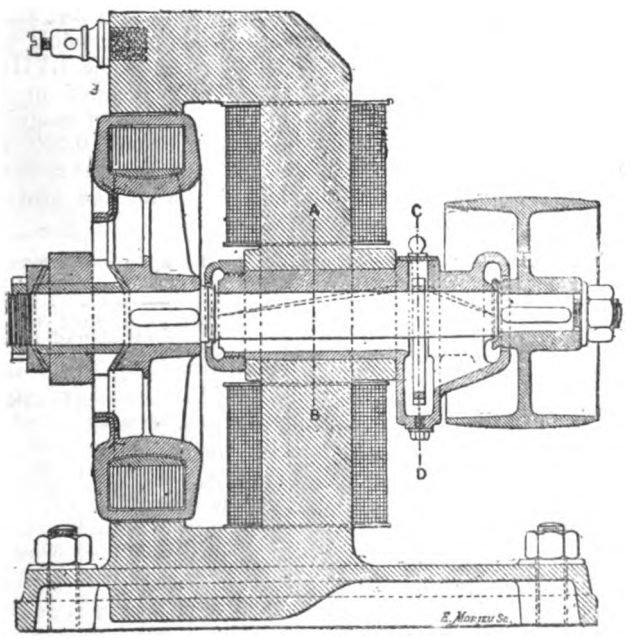

FIG. 1.

Lubricating channels are cut in it, and in the lower part is a larger channel, *r*, through which the oil that has been used is collected and returned to the reservoir, R; this channel runs the whole length of the bearing in a direction parallel with the axis of the shaft. It thus causes a solution of continuity in the frictional surfaces of the shaft and the bearing, which is very necessary for good lubrication. Thus, any dirt which may get into the lubricating channels will be carried along by the oil till it meets the drain *r*, by which it will pass into the reservoir R, where it will settle. With other systems of lubrication this dirt might stop at some point of the circumference, collect more, and thus cause friction.

Lateral play must be restricted as much as possible; otherwise the armature might partially pass out of the

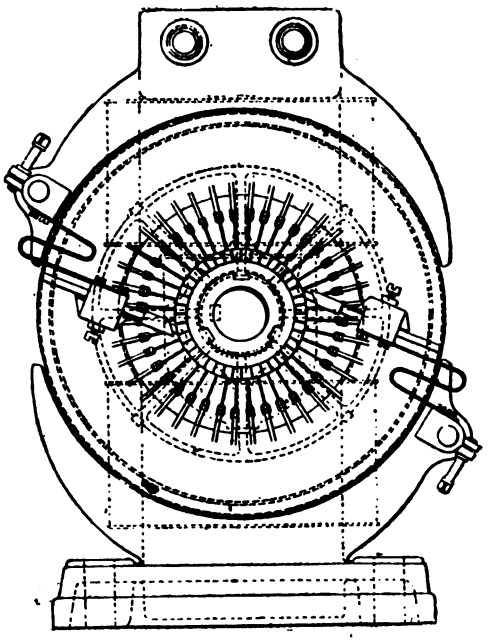

FIG. 2.

field. A maximum play of $\frac{1}{12}$in. to $\frac{1}{24}$in. has been adopted, limited on one side by a collar on the shaft, and on the other by a pulley. The oil is kept from being projected outwards, and more particularly from being thrown on to

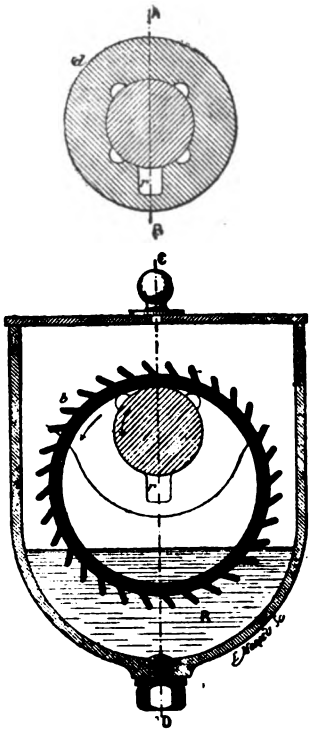

FIG. 3.

the field coils, by the use of two rings, which continually send the oil back towards the middle of the bearing. In small machines these rings may be replaced by collars of the same shape on the shaft and on the pulley.

The interpolar angles are very small; the pole-pieces are specially studied to ensure the most regular distribution of flow in the armature. In examining the design it will be seen that simplicity of construction has been combined with elegance of form. The space occupied by these dynamos being small, and the weight reduced as much as possible, renders them very suitable for motors, especially when driven direct with a coupling.

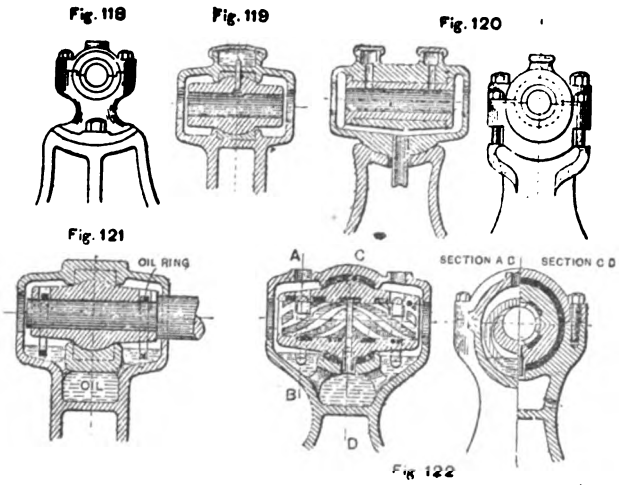
PRACTICAL NOTES ON DYNAMO CALCULATION.*

BY ALFRED E. WIENER.

(Continued from page 374.)

(c) *Pedestals and Bearings.*—In the design of the base, especially when the portion of the field frame above the armature centre cannot be lifted off, care should be taken that the armature can easily be withdrawn longitudinally by removing one of the bearing pedestals, which, therefore, should be a separate casting. In machines where the lowest point of the armature periphery is in a considerable height above the base—as, for instance, in dynamos of the over-types,† Figs. 68, 71, 78, and 86 respectively, further, of the vertical double types, Figs. 77, 82, 87, 99, and 104 respectively, and of the radial and tangential outer-pole types, Figs. 88 and 90 respectively—it is preferable that the pedestal should be made of two parts, the upper part, which should have a depth from the shaft centre a little in excess of the radius of the finished armature, being removable, while the lower portion, which may be cast in one with the base, will form a convenient resting place for the armature in removal.

In most cases this problem of making high pedestals of two parts can practically be solved by boring out the pedestal seats together with the pole-pieces, thus providing a cylindrical seat for the pillow blocks, as shown in Fig. 118. This design is particularly advantageous also for machines in which the base forms one of the pole-pieces, as, for example, the forms shown in Figs. 73, 79, and 99, as in this case, outside of the finishing of the core seats, this boring to a uniform radius is the only tooling necessary for the base.



If the field frame is symmetrical with reference to the horizontal plane through the armature centre, the frame of the machine is usually made in halves, and the armature, in case of repair, can be removed by lifting it from its bed without disturbing the bearing pedestals. The bearing-boxes must for this purpose be made divided so that all parts of the machine above the shaft centre are removable. This design affords the further advantage that the bearing caps can be taken off at any time and the bearings inspected, and it has for this reason become a general practice in dynamo design to employ split bearings, even for types in which the armature cannot be lifted.

It is further of great importance that the bearings should not only be exactly concentric, but that they also should be accurately in line with each other; for large machines it is therefore advisable to effect automatic alignment by providing the bearings with spherical seats. This can be achieved either by giving the enlarged central portion of the shell a spherical shape, Fig. 119, or in providing the bottom part of the box with a spherical extension fitting into a spherical recess in the pedestal, Fig. 120.

In order to prevent heating of the bearings, the shells in modern dynamos are usually furnished with some automatic oiling device, the most common form of which, shown in Fig. 121, consists of a brass ring or chain dipping into the oil-chamber of the box and resting upon and turning with the shaft, thereby causing a continuous supply of oil at the top of the shaft. A further improvement of this self-oiling arrangement, patented in 1888 by the Edison General Electric Company, is illustrated in Fig. 122. In this the interior of the shell is provided with spiral grooves filled with soft metal, and forming channels for conveying oil from each end of the bearing to a circumferential groove which surrounds the shaft at the centre of the shell, and which communicates with the oil-chamber beneath the bearing. These grooves not only effect a steady supply, but a continuous circulation of oil, the latter being lifted from the reservoir into the shell by the oiling rings, thence forced by the spiral channels into the central groove, from where it flows backs into the oil-chamber.

46. *Joints in Field-Magnet Frame—(a) Joints in Frames of One Material.*—Magnet frames consisting of but one material may either be formed of one single piece or may be composed of several parts. If the frame is of cast iron or cast steel, in small dynamos usually the former is the case—*i.e.*, the whole frame is cast in one—while in large machines it generally consists of two castings; if, however, wrought iron is used, it is, as a rule, much more convenient to forge each part separately and to build up the frame by butt-jointing the parts. In so jointing a magnet frame it is of the utmost importance to accurately adjust and finish the surfaces to be united, so as to make the joint as perfect as possible, for every poorly-fitted joint, by reduction of the sectional area at that point, introduces a considerable reluctance in the magnetic circuit. If, however, the contact between the two surfaces is as good as planing and scraping can make it, a practically perfect joint is obtained, and the additional reluctance, which then only depends upon the degree of magnetisation, is entirely inappreciable for such high magnetic densities as are employed in modern dynamos. Experiments have shown that at low densities the additional magnetomotive force required to overcome the reluctance of a joint is very much greater comparatively than at high inductions, which is undoubtedly due to the pressure created by the magnetic attraction of the two surfaces across the joint, this pressure being proportional to the square of the density. The following Table LVIII. shows the influence of the density of magnetisation upon the effect of a well-fitted joint in a wrought-iron magnet frame, the induction in the iron ranging from 10,000 to 120,000 lines per square inch, and indicates that the reluctance of the joint becomes the less significant the nearer saturation of the iron is approached.

TABLE LVIII.—Influence of Magnetic Density upon the Effect of Joints in Wrought Iron.

Density of magnetisation. $\mathfrak{B}$ lines per square inch.	Pressure on joint due to magnetic attraction. $\frac{\mathfrak{B}^2}{72{,}134{,}000}$ lbs. per sq. in.	Magnetomotive force required for 1in.		Difference due to joint $\mathfrak{U} = \mathfrak{U}_2 - \mathfrak{U}_1$ ampere-turns.	Equivalent of joint	
		Solid $\mathfrak{U}_1$ amp-turns	Jointed. $\mathfrak{U}_2$ ampere-turns.		Air-space $\frac{\mathfrak{U}}{\cdot 3133 \times \mathfrak{B}}$ inch.	Length of iron $\frac{\mathfrak{U}}{\mathfrak{U}_1}$ inch.
10,000	1·4	1·7	6·7	5	·0016	3·0
20,000	5·5	3·2	12·6	9·4	·00155	2·9
30,000	12·5	5	19·1	14·1	·0015	2·8
40,000	22	7	25·2	18·2	·00145	2·6
50,000	35	9·5	31·4	21·9	·0014	2·3
60,000	50	12·7	38·1	25·4	·00135	2·0
70,000	68	18·3	45·7	27·4	·00125	1·5
80,000	89	27·6	55·2	27·6	·0011	1·0
90,000	112	50·8	76·2	25·4	·0009	0·5
95,000	125	68	91·8	23·8	·0008	·35
100,000	139	90	110	20	·00065	·22
105,000	153	134	150	16	·0005	·12
110,000	168	288	300	12	·00035	·04
112,500	176	391	400	9	·00025	·023
115,000	183	500	506	6	·00016	·012
117,500	192	600	603	3	·00008	·005
120,000	200	700	700	0	·00000	·000

At a magnetic density of $\mathfrak{B} = 10{,}000$ lines of force per square inch, each joint in the circuit is equivalent to an air-space of ·0016in., or has a reluctance equal to that of

* From the *Electrical World* (New York).

† In Chapter 41, page 249, the names "over-type" and "under-type" were accidentally exchanged, the former corresponding to the inverted and the latter to the upright single-horseshoe type.

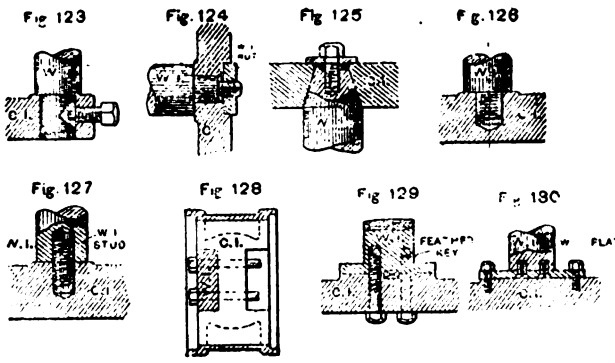
Digitized by Google

an additional length of 3in. of wrought iron; at $\mathfrak{B} = 100{,}000$ lines per square inch, the thickness of an equivalent air-space is only ·00065in., which corresponds to the reluctance of ·22in. of wrought iron at that density; and at or above $\mathfrak{B} = 120{,}000$, finally, a good joint is found to have no effect whatever upon the reluctance of the circuit.

(*b*) *Joints in Combination Frames.*—For magnet frames consisting of two or three different materials the same rule as for frames of one material holds good as to the nature of the joint, but since the ordinary butt jointing would limit the capacity of the joint to that of the inferior magnetic material, it is essential in the case of combination frames to increase the area of contact in the proportion of the relative permeabilities of the two materials joined. Thus, if wrought and cast iron are butt jointed, the capacity of the joint is reduced to that of the cast iron, whereby the advantage of the high permeability of the wrought iron is destroyed and the permeance of the circuit is considerably increased; and in order to have the full benefit of the wrought iron, the contact area of the joint must be increased proportional to the ratio of the permeability of the wrought iron to that of the cast iron at the particular density employed.

For a density in wrought iron of 100,000 lines of force per square inch, for example, a magnetomotive force of 90 ampere-turns is required per inch length of the circuit, and the same specific magnetomotive force is capable of setting up about 40,000 lines per square inch in cast iron; the contact area of a joint between wrought iron and cast iron in this case must therefore be increased in the ratio of 100,000 : 40,000, or must be made 2½ times the cross-section of the wrought iron, in order to reduce the permeability of the joint to that of the wrought iron.

In practice this problem of providing a sufficiently large contact area between a wrought and a cast iron part of the magnetic circuit may be solved either by setting the



wrought iron into the cast iron, or by extending the surface of the wrought-iron part near the joint by means of flanges; or, finally, by inserting an intermediate wrought-iron plate into the joint. In Figs. 123, 124, 125, and 126 are shown four methods of increasing the area of the joint by means of projecting the wrought-iron core into the cast-iron yoke or pole-piece, differing only in the manner of securing a good contact between the parts, the first one employing a set screw, the second one a wrought-iron nut, and the third one using a conical fit with draw-screw for this purpose, while in the fourth one the threaded projection of the core itself forms the tightening screw. Fig. 127 illustrates a modification of the method shown in Fig. 126, a separate screw stud being used instead of the threaded extension of the wrought-iron core. In case of rectangular magnet cores the arrangement shown by plan in Fig. 128 effects an excellent joint; in this the cores are inserted into the base from the sides, thus offering three surfaces to form the contact area. The manner of supplying the necessary joint surface by flanged extensions of the wrought-iron core is illustrated in Fig. 129, which shows the method of fastening employed in large multipolar machines, feather keys being used to secure exact relative position of the cores. In Fig. 130, finally, a joint is shown in which a wrought-iron contact-plate is inserted between the wrought-iron core and the cast-iron yoke or pole-piece with the object of increasing the area of the joint and of spreading the lines of force gradually from the smaller area of the wrought iron to the larger of the cast iron.

47. *Permeability of Various Kinds of Iron—Absolute and Practical Limits of Magnetisation.*—The field magnet of a dynamo has the function of supplying to the interpolar space in which the armature conductors revolve magnetic lines of force in a number sufficient either to cause the generation of the required E.M.F., in case of a generator, or to produce a motion of the desired power, in case of a motor. The cross-sections of the various parts of the field-magnet frame—that is, of the iron structure constituting the path or paths, for the flow of these magnetic lines—consequently must be dimensioned with reference of the number of lines of force to be carried, and to the magnetic conductivity of the material used.

The number of lines which by a certain exciting power or magnetomotive force can be passed through a portion of a magnetic circuit depends upon the area of the cross-section and on the magnetic conductivity of the material of that part of the circuit. The various magnetic materials, according to their hardness, have a different capability of conducting magnetic lines, the softest material being the best magnetic conductor. The specific magnetic conductance of air being taken as unity, the relative magnetic conductance or the relative permeance of the various magnetic materials is indicated by the ratio of the number of lines of force produced in unit cross-section of these materials to the number of lines set up by the same magnetising force in unit cross-section of air. This ratio or coefficient of magnetic induction is called the magnetic conductivity, or the permeability of the material.

The number of lines per square centimetre of sectional area set up by a certain magnetising force in air is conventionally designated by $\mathfrak{H}$, that in iron by $\mathfrak{B}$, and the permeability by the symbol μ. Between these three quantities, therefore, exists the relation

$$\mu = \frac{\mathfrak{B}}{\mathfrak{H}}, \text{ or } \mathfrak{B} = \mu \times \mathfrak{H} \quad . \quad . \quad . \quad . \quad (136)$$

Since for air the permeability $\mu = 1$, the number of lines of force per square centimetre of air is numerically equal to the magnetising force in magnetic measure—*i.e.*, in current-turns. Permeability is therefore often also defined as the ratio of the magnetisation produced to the magnetising force producing it.

While the permeability of air and of all non-magnetic substances is a constant—for air it is 1, and for diamagnetic materials slightly less than 1, for all stages of magnetisation—that of magnetic materials varies with the degree of saturation; the more lines a certain cross-section of iron carries the less permeable is it for additional lines. At a certain limit, for every kind of iron, a very material increase in the magnetising force does not appreciably increase the magnetisation induced, and the iron is then saturated with lines of force. This limit of magnetisation in annealed wrought iron is reached at a density of about $\mathfrak{B} = 20{,}200$ lines per square centimetre, or 130,000 lines per square inch; in soft steel at $\mathfrak{B} = 19{,}800$ lines per square centimetre, or 127,500 lines per square inch; in mitis iron at $\mathfrak{B} = 19{,}000$ lines per square centimetre, or 122,500 lines per square inch; in cast iron, with a 6·5 per cent. admixture of aluminium, at $\mathfrak{B} = 13{,}500$ lines per square centimetre, or 87,500 lines per square inch; and in ordinary cast iron at $\mathfrak{B} = 12{,}000$ lines per square centimetre, or 77,500 lines per square inch of cross-section. The magnetisations, however, to which these materials are subjected in practical electromagnets are taken far below the actual limits of absolute saturation, since "saturation curves" indicating the variation of the induction, $\mathfrak{B}$, with increasing magnetising force, $\mathfrak{H}$, show that from a certain point—the "knee" of the curve—the magnetisation increases much slower than the magnetising force which causes it. In wrought iron, for instance, an induction of $\mathfrak{B} = 13{,}580$ requires a magnetising force of $\mathfrak{H} = 25$, an induction of $\mathfrak{B} = 16{,}000$, a magnetomotive force of $\mathfrak{H} = 50$, and density of $\mathfrak{B} = 16{,}500$ necessitates an exciting power of $\mathfrak{H} = 100$; an increase of 100 per cent. in the magnetising force consequently causes a rise in density of 18½ per cent. at the lower magnetisation, while again doubling the magnetomotive

Digitized by Google

force at the higher induction only causes an increase in magnetic density of about 3 per cent. In practice, therefore, the limits of the magnetic densities of the different materials are to be fixed with regard to the relative economy of iron and copper. Taking the practical limit of saturation too low means a small saving of copper at a large expense of iron, while too high a density effects a comparatively small saving of iron at a large expense of copper. Since copper costs many times more than iron, the densities should be limited rather low, the tendency toward the former extreme being preferable to that towards the latter. With this point in view, the "Practical Working Densities" given in the following Table LIX. are recommended for use in dynamo designing, while under the heading of "Practical Limits of Magnetisation" the highest densities are tabulated that the author would advise to allow in magnet frames of dynamo-electric machines. For sake of completeness the "Absolute Saturation" of the various materials, as given above, are added in Table LIX.

ABLE LIX.—Practical Working Densities and Limits of Magnetisation for Various Materials.

Material.	Practical working density.		Practical limit of magnetisation.		Absolute saturation.	
	Lines per sq. in. $\mathfrak{B}_m$.	Lines per sq. cm. $\mathfrak{B}$.	Lines per sq. in.	Lines per sq. cm.	Lines per sq. in.	Lines per sq. cm.

48.—*Sectional Area of Magnet Frame.*—The magnet frame carries the total flux generated in the machine; according to Chapter 47, consequently, the cross-section of any portion of it must be

$$A_m = \frac{\Phi'}{\mathfrak{B}_m} = \frac{\lambda \times \phi}{\mathfrak{B}_m} \quad . \quad . \quad . \quad (137)$$

A_m = area of magnet frame, in square inches;
Φ = total flux generated in machine, from formula (109), Chapter 36;
ϕ = useful flux necessary to produce the required E.M.F. from formula (91), Chapter 32;
λ = factor of magnetic leakage, preliminary value from Table LII., Chapter 40; final value from formula (110), Chapter 37;
$\mathfrak{B}_m$ = magnetic density in magnet frame, from Table LIX., Chapter 47.

If only one material is used the value found from formula (137) is the uniform cross-section of the whole frame—*i.e.*, of the cores, the yoke, and the pole-pieces; in case of combination frames, however, the area for each material must be calculated separately:

For wrought iron, $$A_m = \frac{\lambda \times \phi}{90{,}000} \quad . \quad . \quad . \quad . \quad . \quad (138)$$

„ cast steel, $$A_m = \frac{\lambda \times \phi}{85{,}000} \quad . \quad . \quad . \quad . \quad . \quad (139)$$

„ mitis iron, $$A_m = \frac{\lambda \times \phi}{80{,}000} \quad . \quad . \quad . \quad . \quad . \quad (140)$$

„ cast iron containing 6·5 per cent. of aluminium,

$$A_m = \frac{\lambda \times \phi}{45{,}000} \quad . \quad . \quad . \quad . \quad . \quad (141)$$

„ ordinary cast iron, $$A_m = \frac{\lambda \times \phi}{40{,}000} \quad . \quad . \quad . \quad . \quad . \quad (142)$$

In combining the averages for the useful flux, taken from Table LI., Chapter 35, for the practical conductor velocities given in Tables VIII., IX., and X. respectively, with the leakage coefficients compiled in Table LII., Chapter 40, the average total flux, Φ, for dynamos of various kinds and sizes is obtained, and by then applying

Digitized by Google

formulæ (138) to (142) the sectional areas of the field frame for various kinds and sizes of machines can be found. In this manner the preceding Tables LX., LXI., and LXII., have been prepared, which give the cross-sections of field-magnet frames of different materials for high-speed drum machines, high-speed ring dynamos, and low-speed ring machines respectively.

The figures given for the areas directly apply to single-circuit bipolar dynamos only; for double-circuit bipolar and for multipolar machines they represent the total cross-section of all the magnetic circuits in parallel, or—for frames of only one material—the total area of all the cores of same free polarity the cross-sections of the various portions of the field-magnet frame are therefore obtained in dividing these figures by the number of magnetic circuits—*i.e.*, by the number of pairs of magnet poles.

For cases of practical design in which the fundamental conditions materially differ from those forming the base for the above tables, the areas obtained by formula (137) may also widely vary from the figures given, but by proper consideration these tables will answer even for such a case, and will be found useful for comparing the results of calculations.

(To be continued.)

WHAT, WHERE, AND WHEN.

Royal Institution, Albemarle-street.

April 5, 9 p.m.—Lord Rayleigh: "Argon."
April 6, 3 p.m.—Lord Rayleigh: "Waves and Vibrations" (sixth lecture).

Institution of Electrical Engineers, 28, Victoria-street, S.W.

April 5, 8 p.m.—Students' Meeting. C. V. Drysdale: "The Practical Measurement of Self-Induction."

Institution of Civil Engineers, 22, Great George-street, S.W.

April 5, 8 p.m.—Students' Meeting. H. Homes, Stud.Inst.C.E.: "The New South Pier, Sunderland."
April 9, 8 p.m.—Discussion on Mr. Thorneycroft's paper on "Torpedo-Boat Destroyers."

Society of Arts, John-street, Adelphi, W.C.

April 8, 8 p.m.—Cantor Lecture. D. Morris, C.M.G.: "Commercial Fibres."

Naval Architects, House of Society of Arts.

April 5, 12 noon.—1. T. Otto Schlich: "Vibrations in Steamers and Torsional Vibrations." 2. W. Mallack: "The Vibrations of Ships and Engines." 3. W. Hök: "The Transverse Stability of Floating Vessels containing Liquids, with reference to Ships Carrying Oil in Bulk."
April 5, 7 p.m.—W. A. Martin: "Induced Draught for Marine Boilers."

Junior Engineering Society, Westminster Palace Hotel.

April 5, 8 p.m.—W. G. McMillan: "The Study of Alloys."

INSTITUTION OF ELECTRICAL ENGINEERS, April 4.

Mr. R. E. B. Crompton (President) in the chair.

At last night's meeting of the Institution the following candidates were balloted for:

Member.—Alfred Henry Walton, 17, South-street, Manchester-square, W.

Associates.—Alfred Henry Avery, Stanley-road, Wallington, Surrey; Charles J. Bosanquet, 73, Queen Victoria-street, E.C.; Thomas William Broadbent, Victoria-lane, Huddersfield; Cadwallader Morgan Van Cuylenburg, the Public Works Department, Singapore; Richard McGillivray Dawkins, Stoke Gabriel, Totnes; Frederick Arthur Glover, 97, Queen Victoria-street, E.C.; John Peal Nelson, 148, Inverness-terrace, Hyde Park, W.; Louis Foley Noakes, 3, Kirkstall-road, Streatham Hill, S.W.; Stuart Richardson, care of Dr. Nelson-Jones, St. Helen's Villa, Swansea; William Walker, 36, Gillott-road, Edgbaston; Arthur Joseph Clarke Waterland, Chadwell Heath, Essex.

Students.—Norman Clough, Sutton Lodge, The Ridgeway, Enfield, Middlesex; Walter F. Daniell, Walpole House, St. Margarets; William Slater Nayler, 58, Lordship-park, Stoke Newington, N.; L. Nieuwenhuys, 39, Westmoreland-road, Bayswater, W.; Reginald Bycroft Roberts, 7, Broomfield-road, Chelmsford; Ernest Claud Short, 17, Northbrook-road, Lee, Kent; Alfred Milligan, Neville James Payn, and Ernest Noblett Ruddock, Faraday House, Charing Cross-road, W.C.

Mr. R. E. Crompton, before throwing open the resumed discussion of Mr. Langdon's paper on "The Employment of the Electric Light for Railway Purposes," announced that Sir David Salomons had presented a further sum (£500) to the Salomons Fund, which now amounted to £2,000. A cordial vote of thanks was passed to the donor.

Mr. W. Langdon, in supplementing his paper by some additional remarks, referred to the question of interest and depreciation mentioned at the previous meeting. He had always regarded depreciation as a bugbear in electric lighting. There was no possibility, he said, of the machinery being allowed to depreciate. The time might come when it would be necessary to replace existing machinery by that of an improved character, so that it might, perhaps, be advisable to make some allowance, which in his case had been put down at 5 per cent.

Mr. J. S. Raworth, who amused the meeting with some remarks on the delights of travelling on railways, congratulated the author on the excellent results obtained in regard to cost. The figures advanced by the author compared favourably with the works cost of central stations.

Mr. R. W. Weekes congratulated the Institution on the valuable paper under discussion. He considered that the last column in Table II. showed careful attention to the economical questions of fuel unless the cost of coal was abnormally low. On the other hand, why was the cost for labour about double that in an ordinary low-tension station? He regretted that the author did not give any information on the question of train-lighting from his large experience in the question in connection with the Midland Railway, and hoped that in the reply the subject would be referred to. The speaker then referred to the results obtained in America in lighting of trains by electricity, and gave the adjoining list extracted from Mr. W. Ward's paper before the American Society of Railway Telegraphists. He pointed out that from it the cost per candle-power hour was less with electric light than with either gas or oil, and that the Lewis system was almost identical with that used by Mr. Langdon.

System of lighting.	Initial cost per carriage.	Initial cost per 16-c.p. lamp.	Total c.p. per carriage.	Cost per day per carriage.	Cost per day per c.p. hour.

Mr. Leonard, the telegraphic superintendent of the South-Eastern Railway Company, referred to the arc light installation put up at the Bricklayers' Arms station as long ago as 1881. Recently, the South-Eastern Company made arrangements with the Charing Cross and Strand Company for the lighting of the arc lamps in the Charing Cross station at the rate of 5d. per unit, including carboning. A similar arrangement had been adopted in regard to the illumination of the Cannon-street Station by the City of London Electric Lighting Company.

Mr. Manville referred to the Portsmouth station, where the current furnished to the arc lamps had been increased from 10 to 12½ amperes, the result being a considerable benefit to the general lighting of the streets. It would be advisable in the future, he thought, to consider the question of increasing the ampereage above 10 amperes to, say, 12½ or 15 amperes. The rectifiers at Portsmouth had answered remarkably well.

Mr. Albright considered that it was a mistake to talk of a 10-ampere arc lamp giving 2,000 c.p. To do so was misleading, as a 10-ampere lamp did not give more than from 1,000 c.p. to 1,200 c.p. Concerning the best system to be adopted for the purpose under discussion, there was no doubt that the direct-current system, whether it was called three-wire or parallel system with middle-wire at 220 or 440 volts, was the best. As to the question of arc lamps, those of over 10 amperes were to be preferred, arranged, say, at a height of 50ft. to 60ft. from the ground. The system which he advocated fulfilled all the requirements suggested by the author in the direction of arc and incandescent lamps and motors from the same unit or units of generating plant.

Captain Sankey discussed the question of coal consumption and its connection with the load curves.

Mr. A. P. Trotter, said that the question was, what was the amount of illumination the railway companies obtained—not so many candle-power but the real lighting effect, or efficiency. The speaker then proceeded to discuss the lighting power of lamps placed at different heights and distances, of different ampereages and points of maximum and minimum illumination.

Mr. Alex. Siemens had something to say of the Albert Docks installation.

Mr. Chamen, who followed, amplified the remarks of the previous speaker in regard to the installation at the East and West India Docks. The system used was direct-current at 220 or 440 volts, and the method fulfilled every requirement. The system really covered an area of five miles, and the 15-ampere arc lamps were run eight in series.

Mr. A. H. Preece commenced to speak as our representative left the meeting after half-past nine. Before it terminated the assembly was expected to bring the discussion to a close.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

EARTHENWARE AS AN INSULATOR FOR STREET MAINS.

The recent gas explosion in the St. Pancras district, referred to in our issue of the 8th ultimo, has incidentally opened out for discussion a possible danger where bare electric light mains are supported on earthenware insulators. While examining the site of the explosion, Major Cardew found a whitish deposit on the insulators of the electric mains. This at first was stated to be caustic soda, but on further investigation it was found to contain pure sodium in sufficiently large quantities to cause violent ignition when water was poured on to it.

We regret that the Board of Trade advisers and our contemporaries should treat this matter as a newly-discovered fact, to be explained or doubted at will. Similar experiences at Paris have for some time been described in standard text-books, and the municipal administrations there have in the interest of public safety absolutely forbidden the use of the conduits in which the deposits occurred. Three of the leading electric lighting societies in Paris have at different parts of their systems used earthenware conduits for the use of low-pressure mains when laid under narrow footpaths. The departure from the usual cement concrete conduit was in order to economise space. The copper conductors were supported in these earthenware conduits on insulators, as shown in illustration to an article appearing in this issue. The whole conditions are therefore somewhat similar to those existing at St. Pancras, but are more favourable to the production of the white alkaline deposits. After a time a similar powder to that described by Major Cardew was found in these conduits, and the production continued till the whole space was choked up by the formation. In the alkaline material formed in this way there was a considerable amount of metallic sodium, and on being thrown into water the mixture ignited explosively.

The engineers of the companies boldly attacked the question before any municipal pressure was brought to bear on them, and have already replaced the earthenware conduits by concrete ones of suitable form. In spite of this evidence our esteemed contemporary doubts the formation of sodium under the condition existing in underground mains, and states that the damp state of the conduit would prevent sodium existing as such were it ever even present. We remember from elementary chemical lectures that Sir Humphrey Davy first obtained metallic sodium by electrolysing damp sodium hydrate, using a pressure from one hundred to two hundred volts. Major Cardew assures us that this hydrate was found at St. Pancras, and the rest of conditions appear to us to be exactly similar, even to voltage, to those used by Davy in these historical experiments. As to the formation of the sodium hydrate from the pottery glaze, we believe that such an action always occurs with commercial glaze when in a damp place. Although the combined silicates of the alkaline metals and calcium silicate form an infusible and insoluble glaze when mixed in the right proportions, we have it from the authority of H. Watts's "Dictionary of Chemistry," that

Digitized by Google

"pure silicate of potassium or sodium, or a mixture of the two even with a sufficient quantity of silica to form a very infusible glass, would still be attacked by water or acid." The silicate of calcium reduces the solubility, but even "the moisture of the atmosphere produces a similar alteration and separates this sodium or potassium, leaving the silica and calcium silicate behind." The opalescent or iridescent film often found on old Roman glass and pottery ware is due to the film of silica left behind by this weathering action. Another chemical authority states that the glaze used on common pottery, although quite good enough for the purpose for which the article is required, is seldom insoluble.

We await with interest the result of the joint deliberations of the Board of Trade with the Royal Society and Institution of Electrical Engineers, and trust that they will not neglect the evidence on the same subject from other countries.

REVIEWS.

Electric Light Installations. In Three Vols. By SIR DAVID SALOMONS, Bart., M.A., etc. Vol. 1—The Management of Accumulators. Vol. 2—Apparatus. Vol. 3—Application. Seventh edition, revised and enlarged. Whittaker and Co., Paternoster-square.

Although somewhat late in the day to refer at length to these volumes, it is a task that pleases. We remember many years ago, unfortunately, a few of the bolder spirits among the scholastic profession inaugurating what proved to be an ephemeral change. The idea suggested, and for a short time carried out, was for an educational society to arrange for the criticism of an educational text-book at its meetings. A member previously appointed opened the discussion upon a particular chapter, and was followed by those present at the meeting who cared to speak, the chairman summing up more or less judicially at the end. It has often struck us that some such plan as this would be admirable education for the students of the Institution. Has the Council once more fallen into a rut; has it no initiation; or what is the matter? This book of Sir David Salomons would form a good text for discussion, and as the aim of the Institution is to obtain truth and promulgate the best practice, a little lively discussion among its younger members would perhaps open the eyes of some of the older men to the fact that ability and talent exist even outside the charmed circle. We suggest a change now and again from so-so papers to pure discussion upon matters of practice, or, if you must have academic discussions, upon matters of theory. Sir David Salomons in this book sets forth the results of practice. He very wisely shirks theories, and contents himself for the most part with describing things that have come under his own observation.

We must reiterate what we have once before said, that the industry at large has never realised its indebtedness to Sir David Salomons. At a time when electrical matters stank in the nostrils of men of the City—that is, of men who in the first place find money to carry out work—Sir David was experimenting upon a large scale at Broomhill and using his utmost endeavours to prove to wealthy men that electricity could be depended upon for lighting their houses. If the Lord of Burleigh should stroll around the country with his bride and once again exclaim

> "Let us see these handsome houses
> Where the wealthy nobles dwell,"

he would find that electricity played a prominent part in them, and we think that many of these installations are due to the initiative of Sir David Salomons. But it will be said this is not reviewing a book. Well, a seventh edition reviews itself. It says, I am wanted, and therefore I am here. Books that possess no individuality, no value, and no information are not sought after, while the very fact of a large sale points to a preponderance of good. The value of what Sir David Salomons writes lies in its practical character. The fittest has survived and is described. When he goes aside and touches theories he enters debateable ground, and is not so good. It may perhaps be well to ask how the heating effect is produced in a conductor if it is merely a directrix? Again, why should the directrix have a different influence upon alternate and direct currents? *Vide* page 195, vol. iii., where reference is made to Lord Kelvin and Prof. Hughes's researches. It is a good plan to follow the old advice, "Be not too hasty to adopt new theories." There is much in the ether theory to which scientific men have to close their eyes and minds and take without consideration, for examination leads them to quagmires deeper than the vaults of Dante's "Inferno." The first book describes the forms of accumulators mostly in use—such as E.P.S., D.P., Crompton-Howell, and Lithanode—the arrangement at Broomhill, and the precautions to be taken in charging, discharging, and testing. The second book discusses the apparatus other than batteries, from the engine to the lamp; while the third volume is a condensed account of the author's practical experience. We are glad to see him so strongly advocating the employment of consulting engineers, and contending that this leads to saving and not expense. His remarks on the precautions to be taken are good; and, indeed, the criticism of the whole work must be: it is good, and should be carefully read and studied.

THE COUPLING OF DYNAMOS FOR ARC LIGHTING.

BY W. H. LEA.

One of the objections to lighting by arc lamps in series is the necessity for the whole of the lamps in the circuit to be burning when two or three only may be required. This means both coal and carbons being burnt unnecessarily. The division of the current for incandescent lamps has been brought nearly to perfection, and a similar thing is required to make arc lighting popular. There is no doubt as to the suitability of the arc lamp for open places, large rooms, or railway platforms, where a good light is wanted.

Lighting by connecting two arc lamps in series on a 110-volt circuit is largely used where it would not pay to put down a separate circuit for the arc lamps, and is sometimes used on large installations. This is, in my opinion, a very unsatisfactory method, as there is the necessity of lighting two lamps where only one may be required, and, also, there is the waste of energy due to the resistance which is placed in circuit with every two lamps. It is acknowledged that the series system is the best for arc lighting, as there is always a reserve of E.M.F. in the circuit to compensate any overdrawing of the carbons or sticking of the mechanism of the lamps. Two of the most successful systems—the Brush and Thomson-Houston—are series systems.

We can, when running incandescent lamps in parallel, put dynamos on the line to take up any increase in the load. Why should we not put machines on in a series circuit, also in series, to give the increase of E.M.F.? Two or more machines can be coupled in series to give, if 1,000-volt machines, a pressure of 2,000 or 3,000 volts. All that is wanted is switching gear to put in or cut them out of circuit. The lamps would have to be controlled by short-circuit switches, and the circuit would have to be a simple series one; no parallel circuits could be allowed, as it would interfere with the switches—except, say, two five-ampere lamps were used on a 10-ampere circuit controlled by one switch.

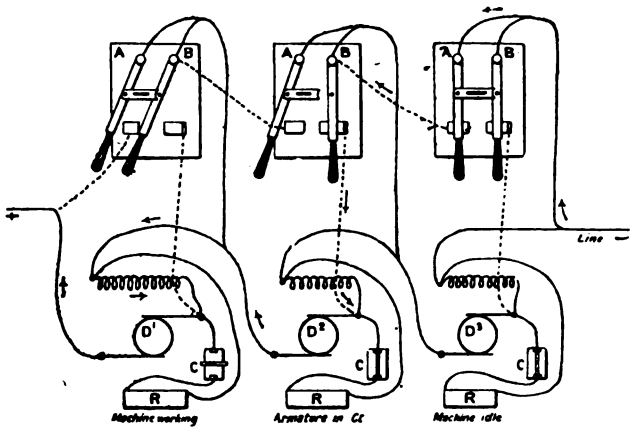
For the sake of description I shall assume that three dynamos are used, each of 1,000 volts and 10 amperes; the switchboard to be fitted with the usual ammeters, a switch for each dynamo, and a switch for each dynamo field. This could be done by using three combination switches, as shown in the sketch.

In this sketch the left-hand machine is working at full pressure; all switches being open, the middle one has its armature in circuit only. It is immaterial whether the

Digitized by Google

machine is running or not, as the armature is simply acting as a conductor. Owing to the fields being short-circuited by switch B, the right-hand machine is not working, as all switches are closed. There is also a resistance, R, across the field terminals, with a switch, C, which may be on the board or not, as most convenient.

We will assume that No. 1 dynamo is working with a full load; in this case the switches of the working machine will be open, and all the rest closed. Now more lamps are put on by opening their short-circuit switches, and we want another dynamo on. After starting and getting up to speed, open switch A, putting the armature in circuit; then, after seeing that the resistance, R, is all out, open the switch B, allowing the current to flow through the field winding—the greater part will pass through the shunt, R. We can, by altering this resistance, adjust the pressure to the required amount by shunting the field current more or less as required. If lamps are still being put on, another machine can be put on in the same manner. If lamps are being put off we first reduce the pressure by shunting part of the current from the field of the dynamo we wish to put off, and if the load is still further reduced the fields are short-circuited by switch B and the dynamo cut out by switch A.



It would be possible with ordinary switches to short-circuit a working machine, which, to say the least, would not improve the winding. To prevent this I propose a compound switch, by which, even if the armature switch were thrown over by a mistake of the attendant, the field switch would make contact first, and rob the field coils of their current. The switch C could be dispensed with, perhaps, by an additional segment to the field switch on the board. If this switch is used the resistance need not be made so large, as would have to be the case if we could not cut out the resistance.

It will be seen by the sketch that the switch B has a longer segment than A. If the switch A is thrown over by a mistake on the part of the man in charge, the switch B will be thrown over by a bar of insulating material between the two switch-bars. This bar is pivoted on switch A, but is only forked at B, and it is prevented from falling by a metal peg on the switch base on which it slides, the peg passing through a slot in the bar. This bar would be used in the case of a mistake. In the ordinary course the switch B would be put over first.

It would, perhaps, be desirable to have an engine whose speed could be varied to a considerable extent, as the slight alterations in the load could be met by altering the speed of the engine. With this arrangement it would be the duty of the dynamo-tender to keep the current constant in the same manner in which the E.M.F. is kept constant in incandescent lighting. It would be immaterial to him how many lamps were lighted, except he was required to note the power expended. In this case a high-tension voltmeter would be required.

An installation laid down on these lines could at any time be extended, it merely being necessary to cut the line at any point and insert one or any number of lamps and put another dynamo in the machine-room if required. This would, I think, be of great advantage for street or railway lighting, where an extension of the lamps might at any time be wanted, as it does not involve any alterations in the existing circuit beyond cutting the line and inserting the lamps.

In submitting this I do not know whether it has been tried before, or if there are any serious objections against it. I leave the type of dynamo and the ratio of the resistance, R, to that of the field coils to persons more qualified to decide these than myself. I am aware that shunting of the field-coil current is used as a means of regulating series electric motors, but I have not heard of it being used in the manner I now describe.

EFFECTIVE ELECTRIC LIGHTING.

BY W. PERREN MAYCOCK, M.I.E.E.

How few electrical fitters know what is meant by effective electric lighting; and of those who do know, how few take the trouble to apply their knowledge to their work. The result is that in ten out of a dozen electrical installations there is too much glare; by this I do not necessarily mean too much light, but too much light thrown in wrong directions. Unshaded lamps are placed so that they throw their light into the spectators' eyes and dazzle them. Especially is this noticeable in badly-lighted shop windows, showrooms, etc., where attention is attracted to details of objects, and the effect of the glare is more apparent than if a cursory glance only were taken.

Because of all this we are constantly hearing persons who, while admitting the superiority of the electric light in every other respect, wind up with the fallacious query, "But isn't it bad for the eyes?" Any intense light, especially sunlight, is bad for the eyes if it is allowed to shine directly upon their retinas. No sensible persons think of looking at the sun—they know what to expect, yet they will stare fixedly at an unshaded arc lamp, and on looking away to other things, and finding that they are dazzled, go away with the thought that there must be something very bad about the electric arc light, which, by the way, approaches more nearly in its character to sunlight than any other artificial light.

The effect of glare exists to a greater or less extent with any unshaded light—gas, oil, or electric. Take an ordinary table oil-lamp, for instance, and try reading a newspaper or book, first with the shade off, and then with it on. The irritating effect of the naked light, and its complete absence when the shade is on, especially if the shade is quite opaque, will be very noticeable.

The distinctness with which objects are seen does not depend so much upon the actual amount of light in a room, as upon the amount of light received by the eye by reflection from the objects themselves. Say one is looking at a picture, and a naked candle is held by the side of it, by far the greater portion of the light received by the eyes proceeds direct from the candle itself; the eyes are consequently dazzled, and the picture is but indistinctly seen. If, now, a shade, such as the hand, is held between the candle and the eyes, the light received by the latter proceeds from the surface of the picture, which is then seen to greatest advantage.

The pupil of the eye, which is the opening through which the rays of light are admitted to the retina, is constantly altering in size according to the amount of light thrown upon it. The less brightly an object is illuminated, the wider must the pupil dilate in order to render vision clear. When an object or objects are very brightly illuminated, the pupil contracts, to prevent an unnecessary amount of light from entering. The effect of light upon the pupil may be studied with a hand looking-glass and a candle. Stare fixedly at the candle flame for half a minute, this will have the effect of closing up the pupil until it is very small in diameter, as will be seen on looking at its reflection in the glass: it will then be observed to gradually dilate, owing to the less illuminated surface of the mirror. Now shut the eyes for two or three minutes, shading them from the light of the candle, and on opening them and looking at the glass the pupils will be found to be much dilated, and they will then gradually close up to suit the brighter light, especially if the candle be held near them.

Digitized by Google

A person coming in from outdoors at night-time has no difficulty in seeing things, as the pupils of his eyes are already widely dilated in his effort to distinguish objects in comparative darkness. On the other hand, anyone going from a well-lighted room into a dimly-lighted one, or into the street, will not be able to distinguish objects until his pupils have gradually dilated to the necessary extent.

The glare or dazzling effect of unshaded lights will now be understood. When one enters a room where there are a number of unshaded incandescent lamps, the eyes instinctively turn towards them, and the bright rays from

FIG. 1.

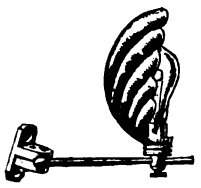


FIG. 2.

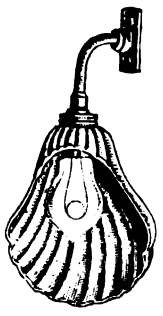

FIG. 3.

the filaments cause the pupils to contract: on looking away from the lamps to objects about the room which do not reflect such intense rays, even though they may be well illuminated, they are indistinctly seen until the pupils have had time to dilate to suit the vision to the less illuminated surfaces. Unshaded lamps have this effect even when they are not looked straight at, if their rays fall obliquely through the pupil upon the retina of the eye.

Electric lamps, both arc and incandescent, require shading much more than do gas or oil lights, as in the former we have a great amount of light proceeding from a very small area, and the rays are consequently much more intense. Compare the area of the filament of a 16-c.p. incandescent lamp with that of a gas-jet of the same power: the light of the latter being more diffused, does not exercise such a dazzling effect upon the eyes.

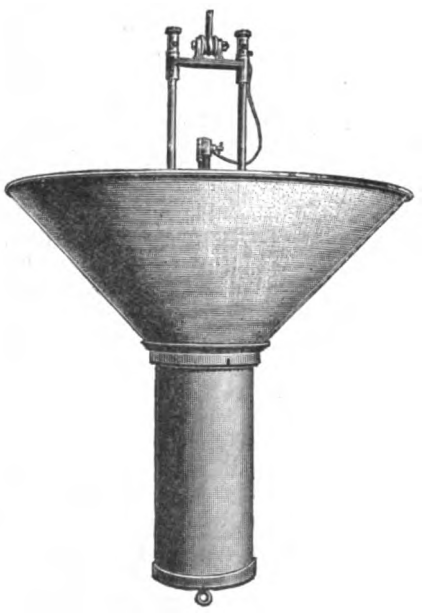

FIG. 4.

Whatever kind of light be used, the most perfect way of using it is to so arrange the lamps that no direct rays can reach the eye from the source itself; the light should be either wholly reflected from surrounding objects, or diffused, preferably the former. In the first case, neither the lamps or their globes can be seen; in the second, the lamps are surrounded by translucent globes, which diffuse or split up the rays from the arc or filament as they pass through.

The competition among electric light fitters, and the consequent cutting down of prices, is no doubt the cause of much of the bad work to be seen everywhere. Shades cost money, and so do intelligent fitters; but even when good prices are obtained the proper shading of the lights is often not seen to, in order to increase the profit: a very short-sighted policy, as almost anyone can appreciate the difference between a well and a badly lighted room, though they may not be able to give reasons. In many cases, where there is no stint either of money or material, the final result is deplorably bad, through simple ignorance on the part of the foreman, and often also of the superintending "engineer," of the proper distribution and arrangement of lights—a matter which, after all, is very simple, as we have shown above.

When shades are used the lights are often too much shaded, so that an unnecessary amount of light is cut off. It is only necessary to shade lamps on that part which could be seen by a person in the room. For instance, in the case of a wall bracket in a room where general illumination is required, the rays from the lamp in the direction of the wall, the ceiling, the floor, and across the room above the level of one's head, should be unimpeded. This could be best done by having a shade to each lamp of the shape shown in Fig. 1,* the shade being tapered off more or less at the top and bottom, according to the height at which the lamp was placed. These shades are made of nickel or silver-plated metal, or of porcelain or ground glass; and they are capable of being turned round on the lamp-holder so that their position may be adjusted. In conjunction with ornamental brackets they would not look so plain as when seen alone, as shown in the figure. They might be rendered more artistic by serrating the edges, and in the case of porcelain or ground-glass ones, by painting floral designs on the back on an opaque coloured ground. Figs. 2 and 3 illustrate forms of shell reflectors of nickel plate and ground glass respectively. The fittings there shown are intended for shop-window and showroom lighting, but the reflectors could of course be applied to any form of fitting. For the general illumination of a room, the shade in Fig. 2 cuts off too many rays at the top, while that shown in Fig. 3 cuts off too many at the bottom; but in any case they would prevent rays from striking the eye. Shades made of natural shell are very effective, the pearly white interior of the shell forming a very good reflector, while the shell itself, being slightly translucent, allows a soft and diffused light to pass through.

The most natural method of illumination, like daylight illumination, would be a general distribution of light all over the room in the manner above described; but in some cases, as in dining-rooms, studies, etc., many people prefer to have the majority of the light thrown on the table, the rest of the room being comparatively dark; but in these and in any other cases, whatever the distribution of the light, no direct rays from the filaments should be allowed to fall on the eyes.

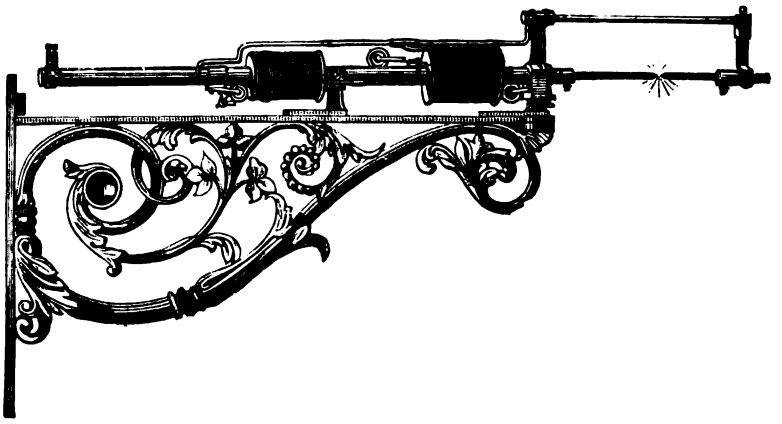

FIG. 5.

Some eyes are more sensitive than others to bright spots of light in a room, as from unshaded lamps; and with everybody these have a tendency to keep the pupils of the eyes in a partially contracted state, which unfits them for

* The electros for Figs. 1, 2, and 3 have been kindly lent by the General Electric Company, of 71, Queen Victoria-street, E.C.

Digitized by Google

obtaining the best visual effect when turned to less illuminated objects. When a given number of lamps are shaded, according to the character and material of the shades, from 30 to 50 per cent. of the light may be cut off: and yet things are seen more distinctly than if the lamps were unshaded, for the reason that the rays of light reach the eyes from the most effective source—viz., from the surface of the objects in the room.

When arc lamps are used, owing to the much greater amount of light evolved for a given expenditure of current, a building or hall with a white ceiling of moderate height may be wholly lit by light reflected from the ceiling, the lamp being turned upside down, and the light thrown upwards by means of an enamelled iron shade. Such a lamp is shown in Fig. 4, and is made by Mr. A. W. Richardson, of Worsley-road, Patricroft, near Manchester. This method of *inverted arc lighting* has been introduced into many workshops, and is a great success. In addition to the advantages to the eyesight already mentioned, there is the consideration that no sharp shadows are thrown by this reflected light. In one case, a room 24ft. square and 12ft. high, with a whitewashed ceiling and lit by one of the Richardson inverted lamps placed in the centre, had a perfectly diffused light everywhere; the diffusion being so good that men sitting at benches with their backs to the lamp could carry out minute work with ease. Messrs. Lowcock, Hill, and Co., of Blackpool and Manchester, also manufacture such lamps at their Cornbrook Works. Improvements have recently been effected in the mechanism of the lamps made by this firm.

The advantages of such a light in workshops, leaving health considerations out of the question, will be appreciated by those who know what a workshop is like with numerous naked gas-jets alight. There are brilliant spots of light here and there on the benches and over the machines, but the jets have to be moved about to suit the work, and even then they illumine it unequally, and give false ideas of shape and size. In cotton and dye mills the inverted arc system of lighting has already made good headway. The murky atmosphere prevailing in manufacturing districts renders artificial light necessary for a good portion of the working hours: and when at first it was attempted to replace gas by ordinary arc lamps, the latter were found useless on account of the hard shadows cast; but since the inverted lamp has been introduced arc lighting has much increased.

Another lamp adapted for reflected lighting is shown in Fig. 5, and is made by Messrs. H. J. Joel and Co., of 31, Wilson-street, Finsbury, E.C. As will be seen, the lamp is placed horizontally on an ornamental iron wall bracket, and the light may either be thrown ceilingwards by means of a reflector, or the lamp may be placed above the ceiling and the light allowed to shine through an opal or frosted glass ceiling light or skylight, the effect being very soft and pleasing. In the case of showrooms, picture galleries, or shops with low ceilings, the plan of placing the lamp above the ceiling will be found very good, much room being thereby saved. We can imagine that in the case of a public hall or large room, with these lamps ranged around the walls, and the light thrown up to the ceiling, especially if the latter had sloping sides, the effect would be very good.

When lamps of the pattern shown in Fig. 4 were used for other than workshop or factory lighting—*e.g.*, in concert halls, assembly rooms, shops, etc.—the underside of the shade and the case containing the lamp mechanism could be concealed by some floral design in wrought metal-work, and the lamps would then look very ornamental.

When the ceiling is too high to reflect the light with advantage, a large umbrella-like shade is placed above the lamp, by which means the light is reflected downwards. In this case, however, the diffusion of the light would not be so perfect.

Although we are not aware that inverted arc lighting has yet been applied to domestic work, we see no reason against its adoption, as there are many patterns of small-current arc lamps on the market which will work two in series off 100-volt mains. There should be no difficulty in adapting one or other of these patterns to inverted work, or a smaller size of the particular make of lamp shown in Fig. 4 might be turned out. The low white ceilings of the generality of houses would lend themselves admirably to such a method of illumination, and we confidently look forward to this as a future departure in domestic interior lighting.

(To be continued.)

EXTRAORDINARY ACCUMULATOR.

Our contemporary *L'Industrie Electrique* has actually unearthed from the columns of a French medical journal a brilliant accumulator, which it has added to its "Old Curiosity Shop." But let this specimen speak for itself; it would be a pity to destroy the lucidity and scientific accuracy of the text:

"The new pamphlet concerning the accumulators is on sale at our offices, where our Paris readers can obtain it by sending one franc. Nothing has been neglected theoretically to explain clearly the object and advantages and to give readers the most detailed explanations about this new apparatus. Our experimental batteries have given such results that we have no hesitation in stating that we have ourselves been surprised at the quality of formation and duration. The accumulation increases, so to say, at a glance. One of the things which have most surprised the engineers who recently witnessed the erec tion of the accumulators is their immediate working, even before being charged with electricity. In effect, their sole manufacture contains the necessary materials for the production of electricity; this, notwithstanding all ancient theories, constitutes a powerful grate of reconstitution struggling against the losses of fluid. Nevertheless, we have desired to leave nothing to chance and reckon even for that loss which seems every day to become less." As the Brothers Griffiths would say, "Chose extraordinaire." We would recommend this masterpiece to the conductors of *Tit-Bits* or *Answers*.

LARGE ARC DYNAMOS.*

BY C. N. BLACK.

Glancing back over the last 15 years and noting the rapid progress made in all branches of electrical engineering, it appears strange that arc dynamos have met with so few changes, more especially so when we remember that arc lighting was one of the first branches of the science reduced to practical use on a large scale. It is impossible to ascribe this to the fact that there was nothing left to be desired in the design or the efficiency of this type of machine, since it has always been notoriously weak in respect to efficiency, and has by no means kept pace with the incandescent dynamo. Within the last 18 months, however, various manufacturers have awakened to this fact, and we have seen the results in numerous descriptions of arc dynamos appearing from time to time in the technical journals. The general tendency seems to be toward larger units and lower speeds; but although the increase in size has, of course, increased the efficiency to some extent, we still notice the massive field magnets with their enormous amount of copper and the small armature, which alone is enough to account for the inefficiency of these dynamos. Another noteworthy fact is that, with one exception, which, perhaps, I need not mention, all the new machines thus far described are of what is known as the closed-coil type. This is the more remarkable when we consider that fully 75 per cent. of the arc lights in this country are run from open-coil dynamos. The open-coil dynamo at the very earliest date appealed to such men as Charles F. Brush and Elihu Thomson as being especially suited for this constant-current work, and, by the remarkable genius of these pioneers, was so perfected that to-day machines with scarcely a single alteration from the design of 15 years ago are being sold in competition with the latest closed-coil dynamos.

The question as to the reasons for this preference natu-

* Paper read before the National Electric Light Association at Cleveland.

Digitized by Google

rally suggests itself, but before answering it, I will briefly describe some of the most marked points of difference between the two classes of machines. As the name implies, the open-coil machine has the separate coils or sections of the windings of the armature entirely distinct one from another. In other words, they do not form a closed circuit. In the open-coil armature each coil or bobbin, as it is generally called, has a large number of turns, and there are but few commutator segments, while in the closed-coil armatures we have exactly the reverse—namely, a few turns per coil, and a large number of commutator segments. This is due to the different manner in which they commutate. In the open-coil machine a large amount of self-induction in each bobbin is by no means objectionable; in fact, one might almost say that it is essential in order to obtain the best results, while in the closed-coil machine the less self-induction there is in each bobbin the better the action at the commutator. The latter is true of all closed-coil machines, whether for arc or incandescent lighting, as all engineers well know who have had any experience in the designing of dynamo-electrical machinery.

The first statement, however, is not nearly as well understood even among those who have had considerable experience with the open-coil machine. The fact that a large amount of self-induction is advantageous in an open-coil machine has never to my knowledge been stated before, although on it depends the successful working of a machine of 2,000 volts or more. Silvanus P. Thompson, in his "Dynamo-Electric Machinery," gives a very clear account of the manner in which an open-coil machine commutates.

To one unfamiliar with the open-coil dynamo it is always a matter of wonder that the commutator spark does not cut away the segments. As a matter of fact, it does so to a certain extent, but the current is so small, and whatever heat there is is radiated so rapidly, that the effects in practice are almost inappreciable. At this point the self-induction of the bobbin plays an important part. Were it not for this, the current in the bobbin which is being cut out would be reversed before the segment had reached a sufficient distance from the brush to prevent the current jumping back across the heated air-space, and thus causing the machine to flash.

The design and proportioning of the field magnets are the same as in the closed-coil machines. It is in the commutator and commutation, then, that we find the most marked difference between the open and closed coil arc dynamos, and herein lies the great superiority of the former over the latter. Take, for example, a new open-coil 125-lighter and one of the latest closed-coil 100-light machines. In the one there are 24 segments in the commutator, while in the other there are 160. To go into details as to which is the easier to insulate and keep in repair is scarcely necessary before a society of practical managers and engineers.

Some advocates of the closed-coil dynamo, however, claim that such a small number of commutator segments causes a discontinuity in the current, and consequently a greater strain upon the insulation of the line. This is not a new objection to the open-coil dynamo, and has been answered long ago. It seems, however, to have been revived recently, and I have noticed that one builder of closed-coil apparatus lays great stress upon the fact that its machine generates an absolutely steady current, and therefore puts no undue stress upon the insulation of the line.

In 1887 Mordey, in England, made the following experiments upon a Brush machine, in order to determine how much fluctuation there really was. Six converters, each made to transform from 2,000 down to 100 volts, had all their primary and all their secondary coils joined in series. The current from the Brush machine was sent through all the low-tension coils, and then, with a Cardew voltmeter, he attempted to measure the difference of potential at the terminals of the secondary or fine-wire coil. The pointer, however, remained at zero, showing absolutely no E.M.F. He then applied the wet hands across the terminals of the whole series, but with equally negative results. An experiment which I myself made not long ago confirms fully these results. The current from a closed-coil dynamo, which had 72 bars in its commutator, and which, therefore, gave practically a steady current, was passed through the field coils of a 125-light arc dynamo, and the fall of potential was measured with a Weston voltmeter. The machine was then run self-exciting, and the drop through the field was again taken. The currents in both cases gave identically the same readings on the voltmeter. That there is a discontinuity in the current no one will deny, but that it is so slight that no instrument less sensitive than a telephone will show it, appears to be conclusively proven by the above experiments. This conclusion being reached, it is difficult to understand how the insulation of the conductor would be more strained by an open-coil than by a closed-coil machine.

A much more vital question in connection with these large units delivering current to the line at the enormous E.M.F. of 6,000 volts or more is this: What value will the E.M.F. attain in case the circuit is suddenly broken? From a theoretical standpoint, basing our deductions on the manner in which the two types commutate, the open-coil machine has largely the advantage. Opening the circuit is the same, in one sense, as suddenly throwing a high resistance into the line; and when we do this we shift the point of commutation back under the brush, owing to the reaction of the armature current being reduced. Consequently, the bobbin, which should not be cut until after its segment has passed from under the brush, short-circuits the one in parallel with it, and as a result the segment connected with this bobbin carries the arc around to the opposite brush, thereby causing the machine to flash; this short-circuits the armature, and the E.M.F. drops to zero. This flash is not due to the insulation breaking down at any point, but is simply drawing the arc of a short-circuited bobbin part way round the commutator, and in this way is acting like a safety valve. The machine is not injured in any way, as as soon as the break in the circuit is repaired it is ready to again deliver current to the line. In order to prove this by a practical demonstration and to learn accurately just what value the E.M.F. attained when the circuit was suddenly broken, we made the following experiment. The sparking distances, from 500 up to 9,000 volts, between two carbon pencils, one with a flat end and the other with a rounded one, were accurately determined within a few thousandths of an inch. The curve is almost a straight line, and, let me add, it agrees very well with that obtained by De la Rue and Muller, who made quite an extensive series of experiments upon sparking distances. The terminals of the 6,250-volt machine were then connected to these carbon pencils, and the greatest distance the current would jump on suddenly breaking the circuit was determined. This distance corresponded to a little less than 8,000 volts, showing that the E.M.F. had risen between 1,500 and 2,000 volts. This can be accounted for by the fact that it takes an appreciable moment of time for the arc on the commutator to be carried from one brush to the other. Owing to each segment extending about 60deg. around the commutator, the time required to short-circuit the commutator is just one-third of what it would be in the closed-coil machine, consequently I think the statement that in a closed-coil machine the voltage would rise to fully double its normal value under the same conditions would be a very conservative one; in fact, I have many reasons for believing that it would go considerably beyond this, providing, of course, that the insulation of the commutator did not break down. If this occurred, the machine necessarily would be unfit to run again until repaired. This peculiarity, if I may be allowed to call it such, of the open-coil machine is especially important where underground circuits are employed, since a breakdown in the insulation, due to an abnormal rise in the voltage, is something that can only be repaired at considerable expense.

Knowing that some tests on underground circuits would be of interest to central-station engineers, I arranged, through the courtesy of E. A. Leslie, of the Manhattan Electric Light Company in New York, to make some determinations as to the rise in voltage when a long underground circuit was suddenly broken. A Brush open-coil 125-light machine was connected to a 12-mile underground circuit, supplying current to 125 arc lamps. The voltmeter registered 6,850 volts at the machine terminals. The circuit was then broken a number of times with the carbon

Digitized by Google

points in shunt with the break. At first the carbons were separated by a distance corresponding to 10,000 volts, and this distance was then gradually reduced until the current jumped the air-space. This indicated only 5,000 volts. The carbons were then set for 6,000 volts, with the result that the current jumped twice in breaking the circuit eight times, showing that we had about reached the limit. It was then decided to try breaking the circuit near the centre. Under these conditions 5,000 volts was the highest reading we obtained, but there was a marked difference in the time of discharge. In the first case there were two discharges in rapid succession within a half second after the break, while in the second case fully two seconds elapsed before the current jumped. In both cases there were two discharges before the arc was established, the first one being short and snappy, resembling a static spark. From this it will be seen that the capacity of the circuit more than counterbalanced any rise in voltage due to self-induction of the machine and line. With these results before us, we can safely assume that the insulation of the cable will not be overstrained by an accidental break in the line.

All these considerations led the company with which I have the honour to be connected to adhere to the open-coil type of machine in designing its large units. The Brush 125-lighter runs at 500 revolutions per minute, and its rated capacity is 125 50-volt 9·6-ampere arc lamps, or 60 kilowatts. It will, however, give 6,700 or 6,800 volts without undue heating. Its weight, including sub-base, pulley, and regulator, is exactly five tons. The frame proper is made of the best grade of soft grey iron, and is cast in three pieces. The two upper caps can be readily removed, thereby giving free access to the armature, which can be taken out and replaced in a very few minutes, in case of necessity. The journals are self-oiling and self-aligning, with gauge-glasses, so that the amount of oil in the well can always be ascertained at a glance. The field-magnet cores are hammered steel, very low in carbon, and showing very high permeability. The pole shoes are steel castings, tapered at the tips to prevent excessive heating due to eddy currents. No. 8 wire is used in the field, which is two sizes larger than on the majority of arc dynamos of other makes. The current per square inch is only 746 amperes, consequently the temperature rises but little, even after a 24 hours' run. The armature is of the well-known standard type, the only difference being that on account of the machine being four-pole, four bobbins are connected in series instead of two.

We now come to the commutator, that part of all continuous-current dynamos which is a source, directly or indirectly, of more perplexity and trouble than all the other parts combined. Three objects were aimed at in designing the commutator for this machine: first, simplicity; second, durability: third, ease of repair. There are three distinct rings, each one of which is built up in sections of thoroughly dried apple wood filled with boiled linseed oil. Over this is forced a mica ring $\frac{1}{16}$in. thick, and on the sides mica discs protect the wood from the arc. Upon the mica are mounted the brass segments, and on these, in turn, the copper. Lignum vitæ blocks $2\frac{3}{4}$in. long serve for insulating pieces between the segments. The brushes are the tangential type, the same as those used in connection with all open-coil dynamos of this design. An automatic regulator, for shifting the brushes and shunting more or less of the current from the field magnets as the load varies, is fastened to the front of the machine, under the commutator. The small shaft which passes across the front is driven through a worm by a small belt from the armature shaft. On this shaft are mounted two magnetic clutches, which are regulated by two relays in the wall controller. The electrical energy consumed in operating the regulator is less than one-tenth of 1 per cent. of the output of the dynamo. The machine is absolutely automatic, from one lamp to the full capacity, and the whole load may be thrown on or off with impunity.

The characteristic curve of this machine without any regulator is remarkable from the fact that after we get over the bend the curve is almost perpendicular, and is probably the nearest approach to a constant-current machine ever attained. By winding more wire on the armature we could have made this machine deliver a constant current of 9·6 amperes at all loads without shunting any of the current from the field; but this would have increased the internal resistance, and also have made the machine much less efficient at light loads. By the present method of regulation we reduced the C^2R loss at one-quarter load from 4,018 to 3,367 watts, or, in other words, we gain almost 1 e.h.p.

The electrical efficiency at full load reaches 94 per cent., which is accounted for by the liberal allowance of iron in the armature, thus reducing the reluctance of the magnetic circuit, and by the large size of the wire used on both field and armature. At full load the commercial efficiency is over 90 per cent., and approaches very closely the efficiency of incandescent dynamos of equal capacity, but the most noteworthy point is the high efficiency shown at one-quarter load.

A NEW METHOD OF MEASURING ILLUMINATION.*

BY EDWIN J. HOUSTON AND A. E. KENNELLY.

(Concluded from page 376.)

In the same way, the amount of light required to permit the performance of other kinds of work is readily determinable. It is evident, therefore, that our illuminometer is applicable to the determination of the question as to whether the illumination of a given area is, or is not, sufficient for the character of work to be done, and that the measurement of illuminations can be made with a reasonable percentage error for all intensities within the range of the apparatus. This range can be varied by altering the character and dimensions of the window, as well as the character and dimensions of the test object.

It will be evident that the advantage of such an instrument consists in the fact that it entirely dispenses with the necessity for the use of a portable standard of light, thus removing a constant source of unknown error in apparatus previously employed for this purpose. Moreover, the instrument does not require any great skill in its use, and with simple directions for use can readily be employed by an inexperienced observer.

It is evident that our illuminometer will permit a direct determination of the candle-power of a source of light by measuring the illumination produced at a fixed distance by that source of light alone. Thus, for example, if an incandescent lamp has its illumination measured at a distance of one metre from the centre of the filament, the number of luxes indicated by the instrument when its window is perpendicular to the rays from the lamp, and all other sources of light are cut off, will give directly the number of international or decimal candles in the lamp. It is, therefore, possible to measure the candle-power of a lamp in its socket, provided all other lamps in the neighbourhood be extinguished, and that a black non-reflecting cloth be placed so as to prevent any appreciable amount of light from entering the windows, except that radiated directly from the lamp. Our illuminometer, therefore, becomes indirectly a portable photometer. In the use of the instrument care must be taken to keep the glass of the eye-piece and of the window clean, as otherwise the observations may be vitiated. The use of the focussing eye-piece is intended to avoid the necessity that might arise for wearing glasses, by which the quantity of light entering the pupil of the eye from the test object would be necessarily reduced.

Since the indications of our instrument depend upon the physiological effect alone, and not on the contrast of an unknown with a known illumination, all questions as to difference of colour in the illumination to be measured are avoided, so that a measurement of the intensity—*i.e.*, the candle-power of an arc lamp—can be made without employing a special arc standard.

Apart altogether from the use of our apparatus, the National Electric Light Association doubtless recognises the fact that there exists to-day no generally accepted standard of illumination. We would respectfully recommend that the association consider the advisability of

* Paper read before the National Electric Light Association Cleveland, February, 1895.

Digitized by Google

adopting as the unit of illumination the lux, or bougie-metre—*i.e.*, the illumination produced by a decimal candle at a distance of a metre. This unit has been under consideration for some years, and has been provisionally adopted by several writers in this country and Europe.

THE SELECT COMMITTEE ON TELEPHONY.

The committee which is enquiring into the adequacy of the telephone service in the country met again last Friday, the Postmaster-General (Mr. A. Morley) occupying the chair.

Bailie Chisholm, a magistrate and a member of the Corporation of Glasgow, in answer to **Sir C. Cameron**, said that in April, 1893, a special committee of the Corporation was appointed to consider the question of obtaining a license from the Post Office to establish a telephone exchange. The result of their deliberations was that it was resolved to apply to the Postmaster-General for a license, and a license was applied for on August 12, 1893. This was done owing to the very unsatisfactory nature of the service now supplied. There were continual complaints of the difficulty of getting connection and of interruptions in conversation. There was only one way of getting rid of these difficulties, and that was by having a twin-wire system, which could only be established by the company having access to the streets This the Corporation would resist to the utmost, as they had already taken over the gas and water pipes, sewers, tramways, and electric light mains. Therefore great complications would arise if the telephone company had facilities to take up the streets. The National Telephone Company was very heavily capitalised, and that would prevent their lowering their prices. The Corporation, however, could raise money very cheaply, and could afford to work at a lower price. The present subscription was £10, and he was satisfied that with a lower subscription the telephone would be much more used by ordinary citizens. The subscription was £20 some time back, and since the reduction the number of subscribers had largely increased. The price in continental countries, and especially in Stockholm, was much lower. From estimates laid before the committee they believed that a thoroughly efficient service could be given at an annual charge of £5. In the course of the negotiations with the Post Office the Corporation had had no official communication from the Post Office to say that their application would be refused.

The **Witness**, examined by **Mr. Fletcher Moulton**, said that he had not given any special attention to the Telegraph Act of 1892, except in connection with this question. He knew of the provision which required the telephone company to get the consent of the local authority before they interfered with the streets. That was a provision in favour of the local authority which ought not to be tampered with in any way. The agreement between the Post Office and the company required the Postmaster-General to connect by underground wires any exchange when asked to do so. As he understood, the Post Office would not require the consent of the local authority to interfere with the streets when required by the telephone company to connect exchanges. He had read the agreement between the Post Office and the telephone company, and in that agreement, he believed, there was absolutely no protection for the public as to the charges that could be made. That, he thought, was a very unsatisfactory state of things.

Sir J. Goldsmid : Have you taken the trouble to enquire as to the proportion of interruptions to the number of messages ?—No.

Will you take it from me that the number of exchange calls in Glasgow per day for last year was 28,213, and the proportion of complaints 3·79 ?—Yes ; but there are thousands of informal complaints.

You told us just now that the Corporation could have nothing to say to the Post Office if they wanted to go under the streets ?—I still think they have practically no power to oppose them.

Clause 12 of the agreement says that so long as it is in force the Postmaster-General shall, on the request of the company, connect exchanges by underground wires. The method of action is determined by 26 and 27 Victoria, which says that the method in which the Postmaster-General is to carry this out is that he shall consult with the local authority, and, subject to appeal, shall not take his wires under any street except with the consent of the local body having the control of the street. Are you aware of that provision ?

The **Chairman** : I would suggest it would be better to recall Sir Robert Hunter on this point.

Sir J. Goldsmid : It is as clear as noonday. The hon. and learned counsel (Mr. Moulton) got completely off the rail.

In answer to further questions by **Sir J. Goldsmid**, the **Witness** said he had considered the disadvantage to subscribers of being on different exchanges. No doubt many persons would have to subscribe to both where there were two. He had not made any enquiry which satisfied him that the conditions in Stockholm were the same as in Glasgow. In London the area covered was 630 square miles, and he understood that the area covered in Stockholm was 43. He was not aware of the rate of wages paid to operators in Stockholm, but he would take it from the hon. member that it was under 2s. a day. In London it was 5s.

Sir J. Goldsmid : I suppose it is not less in Scotland ?—No Scotchman would take less than an Englishman.

By **Mr. Snape** : A reduction in price unaccompanied by an improvement in the service would certainly not satisfy the Corporation. He did not think that the Corporation would make any difficulty in the event of a license being granted about handing over their undertaking to the Government on reasonable terms on the expiry of the license.

The **Chairman** : You are aware that if I had granted a license, your Corporation would have had to come to Parliament for powers to establish an exchange ?—I believe there is some difference of opinion on that point, but even if that were the case there would be no difficulty about the Corporation's coming to Parliament.

Would your proposal, if you came to Parliament, be to buy up the system of the company as you have bought up the undertakings of the gas and water companies ?—If the telephone company at present had, as the water and gas companies had, the right to lay pipes in the streets that might be necessary ; but that is not intended now.

Have you formed any estimate of the number of subscribers you would secure for your municipal system ?—No, but I am sure the number would double or treble itself if the price were reduced.

Bailie Colquhoun, a Writer to the Signet in Glasgow, a member of the Corporation, and a member of the Telephone Committee, corroborated the last witness as to the unsatisfactory nature of the service at present. He could see no practical difficulty in working two systems in the same area. The Corporation would be prepared to take a license terminating at the same time as the license of the company and to hand over their undertaking to the Government, if they desired to acquire the telephones, upon reasonable terms. In his opinion, the Postmaster-General had a practical right to use the streets. It would be really impossible for the Corporation to prevent him from opening the streets, and under the agreement with the telephone company the Postmaster-General was bound, on the request of the company, to connect exchanges The assent of the Corporation to an interference with the streets by the Postmaster-General could not be with-held except on reasonable grounds, and then there was an appeal to the sheriff.

By **Mr. Fletcher Moulton** : If a social necessity like telephones was to be in the hands of a private company, conditions as to efficiency and a maximum price ought to be imposed. They should be sufficient to secure effective service at a reasonable price. There were no conditions in the agreement of the Post Office with the National Telephone Company to secure the public from exorbitant prices or an inefficient system. Competition was an inefficient check, and, that being so, there was no protection whatever to the public in the agreement. If the municipality had a license, the price charged for the service would be a sum that would bring a fair return to the Corporation, and competing systems would have to bring down their prices to that level. There were three companies and 11,534 subscribers in Stockholm. If the Glasgow service had been efficient at a reasonable rate, Stockholm would not have been in it with Glasgow.

By **Mr. Benn** : He did not think the present policy of the Government consistent with the former Post Office policy.

By **Mr. Tully** : He did not think that the granting of municipal licenses would have any serious effect on the revenues of the Post Office. The use of telephones did not injuriously affect the telegraph service.

Sir J. Ferguson : Are you aware that in America, where telephones have been very much developed, they are all in the hands of private companies, and not in the hands of municipalities ?—Yes ; but we all know what sort of municipalities they are in America.

Digitized by Google

By the **Chairman**: If the municipality of Glasgow were to get a license the result would be to reduce the price, and that would enable people to subscribe to both exchanges without any increase of cost. There would also be the advantage of the twin-wire system. He was very strongly of opinion that the State should have the telephones. If the State could not take them then the municipalities should be allowed to. He did not think that the granting of municipal licenses would hinder the State from acquiring the telephones, as municipal undertakings would probably be acquired at a much cheaper rate than private undertakings.

Sir James Russell, ex-Lord Provost of Edinburgh, stated that, although the working of the telephones in that city was not so bad as it was in Glasgow, it was very far from satisfactory, chiefly on account of the mixture of voices. He objected to overhead wires because they interfered with the beauty of the city. He had no doubt that the municipality could work the telephones better and cheaper than either a company or the Government. Mr. Graham Bell, the inventor of the telephone, was a native of Edinburgh.

Baillie Anderson also gave evidence, and **Mr. Bisset**, city treasurer of Aberdeen, spoke to the state of things in Aberdeen.

Sir J. Leng, M.P., also gave evidence as the state of things in Dundee.

The committee adjourned.—*The Times.*

HANLEY ELECTRICITY WORKS.

The following particulars have reached us concerning the working of the Hanley electricity works, which were opened in July of last year:

Loans sanctioned, £22,000; capital expended on December 31, £21,145; capacity of plant on December 31, 650 i.h.p.; number of 32-watt lamps fixed on December 31, 8,732. (This does not include the markets, which are all wired, but not connected to mains pending the erection of more power.)

Units delivered to customers	55,086	65,871.

COMPANIES' MEETINGS AND REPORTS.

SHEFFIELD ELECTRIC LIGHT AND POWER COMPANY.

The annual meeting was held on Wednesday at the Cutlers' Hall, Alderman Franklin, chairman, presiding.

The **Chairman**, in moving the adoption of the report and balance-sheet, made a reference to the statement of profit of the Company for the past year. A balance of £585 was brought from 1893, and there was a small balance from the suspense account of £146. 19s. The profit for the last year (£1,943) brought the total to £2,675. This had been reduced first of all by the payment of interest on debentures, which was a new item coming into the report for the first time this year; the proportion of formation expenses written off (£202); and the transfer to the depreciation fund of the very substantial sum of £1,250. The shareholders would see that these sums absorbed £2,143, and left a balance of £531. The first thing that would strike them on looking at the accounts was the obvious position that there was no dividend, but having first of all consoled themselves for that disappointment, the more they looked at the accounts the more the shareholders must feel abundantly satisfied. In whichever way they looked at the progress of the Company, they had, he thought, every reason for encouragement. The profit for 1893 was only £830, whereas for 1894 it was £1,943. No provision whatever was last year made for depreciation, and therefore it came to be a question this year as to whether they should not once for all tackle the question of depreciation in order to put the finances of the Company on the soundest possible basis. At the end of 1892 the 8-c.p. lamps wired numbered 7,734, at the end of 1893 they had increased to 8,419, and at the end of 1894 to 15,672. The electricity supplied in 1892, taking 12 months' supply on the basis of the nine months, was 122,000 units, in 1893 it was 131,000 units, and in 1894 192,000 units. The shareholders would bear in mind that practically it was only nine months ago since the new electric light station was inaugurated and the new system of underground mains started, so that they had only had the benefit of nine months of that capital expenditure coming into that year's revenue account. Therefore he thought that, bearing that fact in mind, and also seeing the remarkable progress which had been made by that very young industry in Sheffield, they had every cause for satisfaction. There was another important side of the account—one that occasioned the directors the greatest possible anxiety—the question of capital expenditure. There was nothing more easy than to spend money for the purpose of getting well in advance of capital requirements, but when they bore in mind that dividends had to be earned upon that capital they would see at once that it required very considerable judgment to be brought to bear in order to come to a right decision. The capital expenditure of the Company during the past year amounted to £17,251, as against £19,689 in 1893. A large portion of that money had been spent in the extension of the Company's mains to the West-End and forward to Ranmoor. The directors were now proposing to lay mains along Clarke-house-road and in the district of Broomhall Park, and instructions had already been given for that work to be done. The shareholders would see that in the very nature of the business there must be a constant expenditure of capital, because wherever the Company spread its nets in order to catch customers, there, of course, money was needed. The directors felt that a dividend had been earned, although it was not being paid, and that the position of the Company, having regard to the depreciation which had been met, might be considered satisfactory. In considering the question of the electric light and its great competition with gas, it must be remembered that the former in its earlier stages was competing with gas in its older age and more efficient stages. Gas to-day stood at about 2s. 2d. per 1,000 cubic feet in Sheffield. He concluded with the expression of a hope that under all the circumstances—the short length of time that the company had been in existence, and the undoubted fact that the experience of gas companies in their earlier years was such as to yield no dividend to their shareholders for many years—they would see they were within measurable distance of dividend.

Mr. Vincent Eadon seconded the adoption of the report, and believed the directors had dealt with the profits in the right way.

The report was unanimously adopted.

On the motion of **Mr. William Stephenson**, the remuneration of the directors, exclusive of the managing director, was fixed at £240 per annum. The retiring directors, Messrs. George Senior and William Tasker, were re-elected. The auditors, Messrs. T. G. Shuttleworth and Son, were also reappointed.

EASTBOURNE ELECTRIC LIGHT COMPANY, LIMITED.

The annual general meeting was held last week, under the presidency of Mr. George Boulton (chairman).

The **Chairman**, in moving the adoption of the report and balance-sheet, said that they would see by the report that a dividend was now offered, which represented an increase on last year. The report and balance-sheet spoke for themselves. It was stated that the Company had an increase this year both in arc and incandescent lamps. In arc lamps there had been an increase of eight, and in incandescent lamps an increase of 2,179. The earnings for the year amounted to £5,910 and the expenditure to £3,337, giving the actual working profits of the Company £2,573. After adding to the reserve £295 of last year's profits, and providing for all mortgage and debenture interests, a balance of £1,540 still remained. Out of this they proposed to set apart a sum of £300 to form the nucleus of a reserve fund. A balance in hand then remained of £1,240, and the directors proposed that a dividend of 7½ per cent. per annum, free of income tax, be declared upon the share capital of the Company. The balance of £441 would be carried to next year's revenue account. The depreciation fund account was £1,825. Since the last annual meeting of the Company circuits had been extended to Upperton, the first lighting of which district took place on October 10. The capital for the Upperton extension had been provided by issue of debentures which had been privately subscribed. The Company's machinery and mains were in excellent condition. They had been taking another matter into consideration—viz., the helping of their customers. They did not think they ought to take all the profit to themselves. They proposed, therefore, to reduce the price of lighting from June 30 next from 9d. to 8½d. per Board of Trade unit. He then moved the adoption of the report and accounts.

Councillor Skinner, in seconding, spoke in a hopeful vein of a continuance of its present prosperity. There was not the slightest doubt that next year, instead of the dividend being 7½ per cent., it would be 9½, and probably 10 per cent.

The report and balance-sheet were then adopted.

On the motion of the **Chairman**, seconded by the **Mayor**, a dividend of 7½ per cent. was formally declared. Mr. J. A. Skinner was re-elected as a director.

Mr. F. Hollins proposed a remuneration of £200 to the directors for their services during the past year, and expressed the thanks of the shareholders with the way in which they had managed the work of the Company. **Colonel Peirson** seconded, and the resolution was adopted.

A vote of thanks to Mr. Wilkinson (engineer) and Mr. Towner (secretary) concluded the meeting.

ALTRINCHAM ELECTRIC SUPPLY COMPANY, LIMITED.

The first annual meeting has been held at 33, Brazennose-street, Manchester, Mr. F. B. Ross presiding.

The **Secretary** (Mr. J. E. Sharples) submitted the report of the directors, which stated that the public lighting of Altrincham and Bowden was commenced on January 1, and had proved in every way most satisfactory. There seemed every prospect of the Company obtaining plenty of customers.

The **Chairman**, in moving the adoption of the report, said that the work of laying the mains was begun towards the end of last September, and at Christmas the three feeding centres (Old Market-place, St. Margaret's Church, and Old Bowden Church) had been connected with the Broadheath generating station. The total length of cable laid was upwards of 14,000 yards. A very gratifying amount of support had been accorded by the public, and the light had given general satisfaction. At present there was connected with the mains an actual equivalent of 2,552 8-c.p. lamps. It was estimated that before the commencement of the next lighting season the number would be at least 5,000. That would be sufficient to pay all the expenses of the Company, and then they would begin to think of dividends. They had received considerable opposition from the gas company, which he thought would not redound to the credit of the gas company. He did not see that the gas company would suffer by their success; there were so many ways in which gas could be used.

Mr. W. P. J. Fawcus, in seconding the motion for the adoption of the report, said he had no doubt that when they got more customers they would be able to reduce the price of the light. There was no reason why electricity should not be produced cheaper than gas, and he looked forward in a few years to the price being reduced from 7d. to 4d. per unit.

The report was adopted.

Mr. F. B. Ross and Mr. W. P. J. Fawcus were re-elected

Digitized by Google

directors, and a sum of £100 was voted to the directors for their services.

ANGLO-PORTUGUESE TELEPHONE COMPANY, LIMITED.

The ordinary general meeting was held last week at the offices, New Broad-street, Sir Alexander Armstrong presiding.

The **Chairman**, in moving the adoption of the report, said he thought the condition of the Company was very satisfactory. After making all deductions, and including the balance brought forward, the amount to the credit of profit and loss account was £10,629. They proposed to place £6,500 to reserve account, increasing it to £20,000, and to carry forward the balance of £4,129. The expenditure on capital account during the year had been £3,226. On December 31 they had 1,178 paying subscribers in Lisbon and 1,199 in Oporto, representing a gross annual value of £15,638, and with the increase which had taken place during the present year their income was now about £16,000 a year. In view of the depressed financial condition of Portugal he thought it was very satisfactory that the progress of the telephone in that country had been in every way successful, for since its introduction its use had gradually continued to increase year by year. Their loss by exchange last year was £2,241, which was really equivalent to 4½ per cent. on their share capital. This loss and the expenditure on capital account had tended to cripple their resources, but still the Company's position was a sound one, and they looked forward at an early date to being able to pay a satisfactory dividend.

Mr. C. L. W. FitzGerald seconded the motion, which was adopted.

DIRECT SPANISH TELEGRAPH COMPANY, LIMITED.

The ordinary general meeting was held last week at Winchester House, Mr. Edmund Etlinger presiding.

The **Chairman** stated that the balance to the credit of revenue account—£4,076—was smaller than they had been accustomed to, and it was £919 less than the balance for the December half of 1893. This was not owing to any increase in their expenses, which, in fact, had been £348 less altogether, but was simply owing to the traffic having been poor. The total receipts had been £10,477, or £1,268 less than in the December half of 1893. He might state that, as regarded the current half-year, an improvement was shown, for while they had small losses of traffic in January and February, they had had an increase in the present month of £485. The outstanding accounts due to the Company included a certain amount which they had claimed from the owners of the ship "Caloric" for the damage done to their cable. Since the publication of the report the action had been tried, and had gone against the Company. The matter was very important not only to their Company, but to all who were connected with telegraphy, for it established certain things by authority of law which, he thought, were not dealt with before. He would not comment on the case, as he was not prepared to say that the matter had yet been finally settled. He concluded by moving the adoption of the report.

Mr. J. Denison Pender seconded the motion, which was carried.

WILLANS AND ROBINSON, LIMITED.

Directors: Mark Robinson, M.I.C.E. (chairman), Sir Gilbert A. Clayton-East, Bart., Captain H. Riall Sankey, R.E. (Ret.), M.I.C.E.

Second half-yearly report of the directors, to be submitted to the shareholders at the ordinary general meeting of the Company, to be held at the City Terminus Hotel, Cannon-street, E.C., on Wednesday, April 10, 1895, at 3 p.m.

The business of the Company continues to increase in a satisfactory manner, as is shown by the following figures:

	First half of year.	Second half of year.	Whole year.
Indicated horse-power of engines ordered in 1893 (old company)...	9,290 ...	9,660 ...	18,950
Ditto ditto 1894	10,815 ...	15,809 ...	26,624

The orders for 1893 greatly exceeded those for any previous year of the old company's existence, and the shareholders will be glad to see that that increase has been not only maintained, but improved upon in 1894. After writing off £2,870. 1s. 9d for depreciation, and providing for interest upon the debentures, the balance to the credit of profit and loss account for the half-year is £8,520 1s. 9d. Out of this the directors propose that dividends be paid at the full rate of 6 per cent. per annum upon the preference shares, and at 7 per cent. per annum upon the ordinary shares (the same as last half-year), together amounting to £6,006. 3s. 10d.; £754. 3s. 4d. is payable to the directors, in accordance with the articles of association, and it is proposed to carry the balance, £1,759. 14s. 7d., to the reserve fund, raising the latter to £2,646. 9s. 11d. The sum available would be sufficient to pay a dividend upon the ordinary shares at the rate of about 11 per cent. per annum, but the directors feel sure of the concurrence of the shareholders in the view that, at this early stage of the new Company's business, the rapid building up of a substantial reserve fund is an object of greater importance than the payment of high dividends. Owing to unavoidable legal delays the Company has but lately acquired possession of the site selected for the extension works; there is, therefore, little probability that the new works will add to the Company's facilities for producing engines during the present year. Pending the completion of new works, the business is necessarily carried on under disadvantages which act very unfavourably upon cost, and therefore upon profits. The restricted space at Thames Ditton, and the limited number of tools available, in proportion to the increasing business, make that increase a matter as much of embarrassment as of gain. It is, nevertheless, a fact full of encouragement for the future. The site selected is at Rugby, about half a mile distant from the station and adjoining the main line of the London and North-Western Railway, with which it will be connected by a siding. About 28 acres were purchased, but of this five acres have been resold as building land. As a temporary measure, premises have been rented at East Molesey for the storage of patterns, etc. A few tools have also been purchased and fixed there, in aid of the works at Thames Ditton. The increase in rent and taxes is due to this cause. There are some other increases in general charges, some of a temporary nature, and others due to increased work. Orders have been taken for some of the Company's water-tube boilers (Niclausse's patent), which are now in course of manufacture at Thames Ditton; but any large development of this business must be postponed until the works at Rugby are completed.

EDISON GOWER-BELL TELEPHONE COMPANY OF EUROPE, LIMITED.

The ordinary general meeting was held last week at the offices, 53, New Broad-street, Sir Alexander Armstrong presiding.

The **Chairman**, in moving the adoption of the report, stated that the suit in connection with the Company's patent rights in Belgium, which had been pending for eight years, had at length terminated in the Company's favour, and the Zurich Telephone Company, working in Namur, had been found in damages and costs. In view of this success, and in anticipation of a satisfactory financial recognition of their claims, the actions entered against other infringers were being proceeded with, and they had every reason to expect the same satisfactory result from these actions as that which had attended their suit with the Zurich company.

Mr. C. L. W. FitzGerald seconded the motion, which was adopted.

SOUTHAMPTON ELECTRIC LIGHT AND POWER COMPANY, LIMITED.

Directors: Mr. G. T. Harper (chairman), Mr. J. F. Obree (vice-chairman), Mr. W. H. Mitchell, Mr. G. J. Tilling, Mr. J. F. Albright. Secretary: Mr. J. T. Hamilton.

Report of the directors to be submitted to the ordinary annual general meeting to be held on Monday, April 8, 1895, at the registered offices of the Company, at 4 p.m.

The progress referred at the last annual meeting has been more than maintained, and in consequence the directors are able to report a net profit of £1,014. 12s. 3d., which, after setting aside £100 for depreciation and £100 for directors' fees, and paying interest on loans and debentures, and writing off the balance of the loss last year (£184. 17s. 10d.), leaves £137. 16s. 7d. to be dealt with. Out of this amount the directors recommend a dividend of 6 per annum on the preference shares, and a dividend of 2½ per cent. on the ordinary shares, which will absorb £102. 2s. 6d., leaving £35. 14s. 1d. to be carried forward. As in last year's report, a statement of revenue and expenses is appended:

STATEMENT OF REVENUE AND EXPENSES.

	Lamps (8 c.p.), Dec. 31.	Units sold.	Revenue. £	s.	d.	Expenses. £	s.	d.
1891 (part only)	—	5,469	350	5	11	535	2	1
1892	2 200	35,537	1,153	4	10	1,152	0	4
1893	3,162	53,848	1,606	14	8	1,121	4	8
1894	3,896 2 cranes = 1,500	*85,501	2,491	6	7	1,676	14	4

* Lighting, 76,685; cranes, 8,816; total, 85,501.

The directors have applied for a provisional order, which they are happy to say is now practically secured. The directors who retire from office are Mr. W. H. Mitchell and Mr. J. F. Albright, who, being eligible, offer themselves for re-election. The auditor, Mr. C. Cox, also offers himself for re-election.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Manchester.—The Lancashire and Yorkshire Railway Company require by the 30th April tenders for the supply of an oil-engine engine packing, signal and telegraph fittings, signal, telegraph and electric light wires, wire, etc.

Stowmarket.—The Urban District Council require by April 15 tenders for lighting the streets of Stowmarket from August 15 next to May 15, 1896, and also for lighting the post office clock. Particulars may be had of Mr. S. Prentice, clerk.

Rangoon.—Tenders will be received by the president of the Rangoon Municipal Committee, not later than November 4, for the lighting of Rangoon by electricity. Tenders should be accompanied by detailed plans, specifications, and estimates, and must state the terms on which the installation proposed will be undertaken. All information regarding the existing system of lighting and the cost, etc., with plan of the town, can be obtained on application to Messrs. Ogilvy, Gillanders, and Co., Sun-court, 67, Cornhill, London, E.C., accompanied by a remittance of £1. 1s. Tenders are to be sent in sealed covers and endorsed "Tender for Electric Lighting, Rangoon." Mr. J. Short, Rangoon, is the secretary of the committee.

BUSINESS NOTES.

Nottingham.—The Exchange Hall is to be lighted by electricity.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,148.

Change of Address.—Mr. E. R. Dale has removed from Sherbourne to St. Edmund's Electric Works, Salisbury.

Removal.—Messrs. Fuller and Co. have removed from Mansion House-chambers to 28, Bush-lane, Cannon-street, E.C.

Direct Spanish Telegraph Company.—For the month of March the receipts were £2,883, as against £1,809 for the same period of 1894.

Newcastle.—The Walker District Council have approved of the plans of Messrs. Parsons and Co. for the extension of their fitting and machine shops.

West India and Panama Telegraph Company.—The receipts for the two weeks ended March 31 were £17 less than for the corresponding period of 1894.

Globe Telegraph and Trust Company.—The directors announce an interim dividend of 3s. on the preference and 2s. 3d. on the ordinary shares.

Fire.—A fire which took place at Millwall on Tuesday morning practically destroyed the premises of Messrs. Statter and Co., electrical engineers, in Cuba-street.

Yeadon (Yorks.).—Mr. Francis H. Medhurst has been called in to advise the District Council on the tenders which have been received for the electric lighting of the town.

Agency.—Messrs. Munro and Mackintosh, of 97, Union-street, Glasgow, have been appointed sole agents in Scotland for the sale of carbons manufactured by Messrs. Richter's, Limited.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 31st ult. amounted to £1,002, as compared with £841 in the corresponding week of last year.

Direct United States Cable Company.—The Board have resolved upon the payment of an interim dividend of 2s. per share, free of income tax, being at the rate of 2 per cent. per annum, for the quarter ended March 31.

Queenstown.—A scheme for the lighting of the port of Queenstown by electricity has been submitted to the Town Commissioners. The estimated cost of the plant, including the building, engine, generator, etc., is about £6,000.

Leeds Tramways.—The House of Lords Standing Orders Committee have decided to allow additional provisions to be added to the Corporation Bill empowering the use of certain sites for stations on which to produce electrical energy.

Dover.—At the request of the Mayor, the Town Council last week decided that, as the electric light works will shortly commence work, the Board of Trade should be requested to send an inspector to enquire into the safety of the wires, works, etc.

Shoreditch.—The London County Council on Tuesday granted an application from the Shoreditch Vestry for a loan of £2,000 on the annuity system for 55 years for purchase of property to widen Bowling-green-walk, and to provide a site for an electric light station.

Eton.—The provisional order granted by the Board of Trade under the Electric Lighting Acts to the borough of New Windsor, in respect of the borough of New Windsor and the Eton urban district, was produced by the clerk at a meeting of the Eton Urban District Council last week.

City and South London Railway.—The receipts of the Company for the week ended March 31 were £932, against £843 for the corresponding week of 1894, or an increase of £89. The total receipts for the current period of the present half-year are £12,648, against £12,035 in the corresponding period of 1894, an increase of £613.

Kendal.—The Town Council had under consideration last week a recommendation of the Electric Lighting Committee in their minutes with respect to the Windermere order, that in opposing it the Corporation should undertake to apply for a provisional order not later than the session of 1897. The minutes were confirmed.

New Zealand Electrical Syndicate.—Mr. Justice North has appointed Mr. J. A. Kelman receiver and manager for the debenture-holders of the New Zealand Electrical Syndicate, Limited. It is stated that this has become necessary solely for the purpose of reconstructing the company, and that the creditors of the company will be paid in full.

Agency.—Messrs. Lea, Sons, and Co., of Pengewerne Works, Shrewsbury, manufacturers of specialities in artistic electric light fittings and general art-metal workers, notify us that they have appointed Messrs. Francis and Spilsbury, Mansion House-chambers, 20, Bucklersbury, London, E.C., general electrical agents and suppliers, as their agents for London, the south, south-western, and south-eastern districts of England, and for Ireland generally.

Cheltenham.—The Town Council were last week recommended by the Electric Light Committee to appoint Mr. Matthews (gas examiner) electric light inspector at a salary of £10 per annum, and that he should receive half the fees from customers for testing their meters; that the surveyor erect an arc lamp as an experimental lamp in the centre of the open space in Clarence-street, and that 500 incandescent lamps of 8 c.p., 16 c.p., and 32 c.p. be purchased.

Whitechapel.—On Monday, at the meeting of the Whitechapel District Board, the long-maturing scheme of electric light came up for decision, and, by a vote of 21 to 11 on a division, the scheme of the Streets Committee, which was estimated to cost an outlay of £44,500, was referred back to the committee. The debate was a long and important one, the chief argument used against the installation being the uncertainty as to the total cost of the scheme, and the doubt as to the amount of income to be derived from the supply of the electric light to private consumers.

Hanley.—The next meeting of the council of the Tramways Institute of Great Britain and Ireland was to take place at Hanley yesterday, when some new features in connection with the North Staffordshire tramways were to be inaugurated. A carriage was to be ready for the members of the institute to see it lighted by electricity, and it is intended to light up the whole of the cars on the line by the same means. The application of the electric lighting of the cars has been entrusted to Messrs. New and Mayne, of London, the batteries being supplied by the Electric Power Storage Company.

Eastern Extension Telegraph Company.—The accounts of the Eastern Extension, Australasia, and China Telegraph Company, Limited, to December 31 show, subject to audit, a balance of profit of £170 937 after payment of three interim dividends. The directors now propose to distribute the usual dividend of 2s. 6d. per share, making a total dividend of 5 per cent for 1894, together with a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the year. For the month of March the receipts show an increase of £2,019 as compared with the corresponding period of 1894.

Portsmouth.—The Electric Lighting Committee of the Corporation met on Thursday of last week and adopted a scheme of extension embodied in a letter from their chairman (Mr. George Ellis). The latter stated that having been requested by the General Sub-Committee to report on the estimated cost of certain extensions of the system with a view to the reduction of charges to the Corporation for public and to other consumers for private lighting, he had with the assistance of the resident engineer, carefully considered the question in all its bearings, and reported that the capital outlay for these extensions would amount to £21,000.

Keswick.—The Urban District Council have adopted a minute of the Electric Lighting Committee to the effect that the committee declined to recommend the Council to give their unqualified assent to the application of the electric light company for a provisional order from the Board of Trade, and recommended the Council to call a ratepayers' meeting to consider the whole question of lighting the town. At a meeting of the Council last week the Council decided to form themselves into committee to obtain information to lay before the ratepayers and to receive any communication that might be received from the electric lighting company.

Bath.—The report of Major Cardew as to the application of the electric light company for a provisional order was circulated on Tuesday. He states that the complaints the local authority have made as to the supply by the present company are justified, and that the company took a too sanguine view as to the rate at which they could produce and supply electrical energy. He recommended that the company be not granted the order unless the Corporation assents to it (such assent having hitherto been withheld), but he expresses the opinion that the Corporation might give that assent provided it is guaranteed powers of purchase, with transference to it of the powers and obligations of the order.

Digitized by Google

Bangor.—It appeared from the Water and Gas Committee's report, presented at a meeting of the Town Council on Wednesday, that the committee had had an interview with Mr. Duce, electrical engineer, whose offer was accepted to furnish a full report as to the means and cost of an installation of electric light plant. Mr. Henry Lewis moved the confirmation of the decision come to by the committee, adding that the suggestion had also been made to construct an electric tramway from the town clock to the proposed pier at Garth. The proposal was adopted, as was also another authorising the Council to engage the services of a consulting engineer as soon as they received Mr. Duce's report.

Birkenhead.—The Finance Committee of the Town Council have had under consideration the plans, sections, etc., prepared by Mr. Shoolbred in connection with the erection of the proposed central station. The committee recommended at a meeting this week that Mr. David Lyon, Birkenhead, should be instructed to take out the quantities in connection with the erection of the chimney, and that tenders should be invited for its erection. Mr. T. Cook moved that this be not confirmed, as he considered it would cause confusion if this contract for the chimney was undertaken by one firm and that for the building itself by another. Mr. Byrne seconded. After some discussion the amendment was lost.

Hove Electric Lighting Company.—The Hove Electric Lighting Company, Limited, which was formed in August, 1892, with a share capital of £40,000 in £5 shares, for the purpose of taking over from the Commissioners of the town of Hove, Sussex, the undertaking comprised in the Hove Electric Lighting Order of 1890, and which has laid down the requisite plant and mains at an expenditure of £48,800, and is now supplying electricity to the town, have this week offered for subscription the balance of 2,851 ordinary shares of £5 each and £12,500 of first mortgage 4½ per cent. debentures, the balance of the authorised debenture capital of £25,000. The shares were offered at the price of £5. 5s. per £5 share and the debentures at £103 per £100 debenture.

Belfast.—The Corporation on Monday adopted the report of the Electric Light Committee. Councillor Masterson thought the report was a very meagre one. The electric light had been supplied to a large number of people in the city, and he thought the Council was entitled to some statement as to how the affair was progressing. Alderman Pirrie said they had at present 4 200 lamps actually on supply, and applications for an additional 1,000 were under consideration. This made a total of about 5 300 lamps that were practically being supplied. The average total cost of the supply for the nine weeks was £26. 10s. 2d. per week, and against that there was an income of £27. 15s. He thought that was very satisfactory considering the short time the works had been in existence.

Worcester.—At a meeting of the City Council on Tuesday Mr. Williamson brought up the report of the Electricity Committee on the bill by the contractor for extras in connection with the Powick generating station, which was referred back to them at the last meeting. He said the legal position had been fully considered, and the town clerk advised that though the contract required a written order for extras, if no such order was given, yet after the end of the engagement, if the architect made a certificate allowing such extra work, it was conclusive and final unless his conduct had been fraudulent. There was no suggestion of fraud, and the committee had to inform the Council that they were obliged to pay. He moved the adoption of the report on Mr. Rowbotham's account. Mr. H. Day seconded. An amendment was carried making an addition to the motion.

Lewis v. The London Electric Supply Company. — The question in this case, which came before Mr. Justice Charles and a common jury on Wednesday, was what damages the plaintiff was entitled to as compensation for having been discharged without notice under the following circumstances: the plaintiff was engaged as general manager of the defendant company at a salary of £600 a year, and his engagement continued until the financial difficulties of the company led to the appointment of a receiver on behalf of debenture-holders, when he was cashiered without notice. For the plaintiff it was contended that he was entitled to a year's salary. On the other hand, Lord Wantage, who held the debentures, offered the plaintiff £150, the equivalent of three months' salary, and it was contended that that was a proper satisfaction of the plaintiff's claim. The jury found that the plaintiff was entitled to £300, in addition to £34. 12s. arrears of salary.

Bankruptcy Proceedings.—At the Edinburgh Sheriff Court House last week, before Sheriff Rutherfurd, Messrs. Browning and Gardner, electrical engineers, carrying on business at 122, George-street, Edinburgh, appeared in the Bankruptcy Court for examination in bankruptcy. In reply to questions by Mr. D. W. Marwick, W.S., on behalf of the trustee (Mr. John Hamilton Buchanan, C A.), Mr. Browning said that he had no papers or books, except the vouchers for petty cash expenditure. On December 18, he gave a bill for £60 to Messrs. Anderson and Chisholm, but he was not sure whether that was the day he was gazetted out of the firm. He did not know he was gazetted out of the firm. The bill was granted for a business account. He could not say whether he received a letter from his partner a week before, terminating the contract of copartnery, and he did not know whether it was before or after that that he granted the bill in the firm's name. Sometimes he corresponded in his own name and sometimes in the firm's prior to December. In reply to a question whether the account had been rendered, he said he did not know. The account was in reference to some law business which had been done relating to the business of Browning and Gardner and the financial position of the concern. The firm in October, 1894, showed a surplus of £150, and the trouble was caused because they had not money in hand.—At the London Bankruptcy Court on Wednesday, Mr. Jonathan Lewis Young was examined under his failure. The debtor is an electrical engineer, and started business in partnership with his brother on Ludgate-hill in 1891, trading under the name of the Edison Mimeograph Company. His gross debts are returned at £3,108, of which £2,958 are unsecured, and there are no available assets. The principal creditors are the Edison Phonograph Company, Limited, for £600, and the Bell Phonograph Corporation for £1,760. The examination was concluded.

Arlecdon and Frizington.—The Urban District Council considered at their last meeting a report presented by Mr. J. S. Brodie, of Whitehaven, who had been requested to report on the lighting of the district by electricity. Mr. Brodie found that the only water power available was from Cogra reservoir. This was suitable within certain limits. He had prepared estimates for three separate schemes. First, to take a 9in. main from Cogra to a point nearly opposite Millgillhead, and have there a turbine to drive a dynamo that would supply current to light the public lamps only. Second, to take a 12in. main from Cogra to Marron Bridge (thus obtaining all the power obtainable from water not required for water-supply purposes) and with two turbines and two dynamos to generate electricity, not only sufficient for public lighting, but also to light 500 16-c.p. lamps for private consumers. Thirdly, Mr. Brodie estimated for a steam-power station at Steel Bank to supply the same current as in the second estimate. In each of these estimates the proposal was to replace 127 oil lamps now in use for public lighting by 150 incandescent lamps averaging 20 c p. each. The current in every case would be alternating at 2,000 volts. The report is now under the further consideration of the Council.

Hampstead.—The Vestry had before them at a meeting last week two recommendations of the Lighting Committee on the subject of lighting the High-road, Kilburn. After a long discussion, it was resolved that the Willesden District Council should be informed that the estimated cost of laying down the necessary mains, with lamp standards and fittings for 24 arc lamps in the High-road, Kilburn, was £1,460, and that the cost of running these arc lamps at the present cost price would be £41 per lamp per annum; also that the Willesden District Council should be asked if, in the event of the Vestry agreeing to light the High-road by electricity, they would be willing to pay half of the said estimated cost, and half the cost for the time being, of running the arc lamps. The committee further recommended that the necessary mains, transformers, etc., should be provided for the supply of electric current to private consumers in various localities, in accordance with the plans and specifications of the electrical engineer, Mr. Chattock: West End-lane (Mill-lane to Hemstall-road), £1,420; and Haverstock-hill (Belsize-avenue to Belsize-grove), Belsize-grove, and Belsize-park-gardens at a total cost of £5,260. Mr. Thwaites, chairman of the committee, said that a large number of applications for the supply of current had been received from the tradesmen in the High-road, one of whom wanted as many as 1,000 lights. The recommendation was adopted. A letter was received from Mr. W. H. Preece stating, in reply to the Vestry's enquiry, that if it was intended that the Vestry's own engineer should superintend and carry out plans submitted by him (Mr. Preece), or plans of which he approved, such a procedure was entirely in accordance with his wish, and as he would be freed from the considerable expenditure he was at present incurring he would continue to act as consulting engineer, and ask a commission of only 2½ per cent. on the cost of the work so carried out; but that if by the word "superintend" it was intended that Mr. Chattock should prepare his own plans, submit his own estimates, and act entirely irrespective of him (Mr. Preece) in carrying out the scheme he had designed and reported upon in accordance with the instruction of the Electric Lighting Committee, he should decline to act as consulting engineer on any terms whatever. After some discussion the letter was referred to the Lighting Committee.

Torquay.—The Town Council had before them on Tuesday the report of Mr. W. H. Trentham. M.I.M.E., on the lighting by electricity of the Bath Saloons, Victoria parade, the Strand, and Torbay-road. Mr. Trentham said the total length of underground main required would be 2,442 yards, and if the usual distance, 66 yards, was allowed between each lamp, 37 arc lamps would be required, or a total of 40 arc lamps. The cost of engine, boilers, dynamos, lamps, posts, cables, etc., would amount to £4,900. He had gone carefully into the cost of gas which would be saved by the use of electricity, and on the basis of what was actually now being paid found it amounted to £368 per annum, the nominal candle-power of the gas lamps being 2 300, against 40 000 given by the arc lamps. This amount (£368) deducted from the total expense of running the electric light plant—that was, £728—showed that they would incur an increased expenditure of £360 per annum. He suggested that the installation should be somewhat increased, sufficient machinery being provided to maintain 800 16-c p. lamps in addition to the 40 arc lamps and the incandescent lighting for the Bath Saloons. The total outlay would then be £7,986, and the annual cost of working would be £1,138. On the other hand, there would be a revenue of not less than £866 from the private incandescent lighting at a charge of 6½d. per unit, which was practically equal to 3s. 3d. per 1,000ft. for gas. The capital sum of £7,986 is made up as follows: engines, boilers, and condenser, including steam-pipes, fixing, etc., £1,850; dynamos, transformers, and meters, £1,240; 40 arc lamps and posts, £1,200; street work,

Digitized by Google

junction-boxes, and cable, £1,275; battery, switchboard, wiring Bath Saloons, alterations to cellar, travelling crane, etc., £1,350; contingencies at 10 per cent., £691; engineer's fee at 5 per cent., £380; total, £7,986. Mr. Trentham assumes that the cellars under the Bath Saloons would be utilised as a generating station. Alderman Kerswell moved that the report be referred back to the committee. He was glad to see that on the first intimation of the probable introduction of electricity the gas company had lowered the price of gas. Mr. Mortimer seconded. The question they had to decide was not whether they would have electricity in the town or not, but whether they would allow a private company to introduce it or retain it in their own hands. The anxiety of the gas company to prove that electricity would be more costly than gas was, in his opinion, a strong argument in support of the introduction of the new light. He hoped, at any rate, that the town would not allow the installation to pass into the hands of a private company. Mr. R. Crocker supported, and the motion was carried.

PROVISIONAL PATENTS, 1895.

MARCH 25.

6114. **An improved filament for incandescent electric lamps.** Frederick William Edmund Jones, 23, Archery-road, Leamington.

6127. **Improvements in feeding nailing and other machines of that class by means of electricity, and in apparatus used in connection with such machinery.** Robert John Jones, 67, Queen's-road, Bootle, near Liverpool.

6163. **Plate for secondary voltaic battery.** William Alfred Baxter Buckland, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

6164. **Automatic cut-out for suspended electrical conducting wires.** Johann Schäfer and Paul Steffens, 28, Southampton-buildings, Chancery-lane, London.

6171. **Improvements in multiple switches for use with double telephonic leads.** Franz Stock, 46, Lincoln's-inn-fields, London. (Complete specification.)

6177. **Improvements in alternating-current dynamos.** William Beedie Esson, Norfolk House, Norfolk-street, London.

MARCH 26.

6192. **Improvements in thermodynamic machines.** William Henry Watkinson, 24, Albion-crescent, Dowanhill, Glasgow.

6256. **Improved construction and arrangement of commutators for dynamos.** John William Gilbert and Samuel Jevons, 77, Colmore-row, Birmingham.

6258. **Improvements in apparatus for the electrolytic decomposition or purification of liquids.** Moritz Stein and Anton Wolf, 433, Strand, London.

MARCH 27.

6318. **New and useful improvements in the method of transmitting electric currents to electric railway cars.** Addison Goodyear Waterhouse, 33, Old Broad-street, London.

6319. **New and useful improvements in electric-current meters.** Addison Goodyear Waterhouse, 33, Old Broad-street, London.

6320. **New and useful improvements in thermostat and electric switches or circuit brakes.** Addison Goodyear Waterhouse, 33, Old Broad-street, London.

6351. **Improvements in dynamo-electric machines.** William Morris Mordey and Silvanus Phillips Thompson, 46, Lincoln's-inn-fields, London.

MARCH 28.

6390. **Improvements in the method of and in apparatus for electrically lighting miners' safety lamps.** John Peel, 8, Quality-court, Chancery-lane, London.

6391. **Improvements in the method of and in apparatus for switching on and off electric currents for electric lighting and other suitable purposes.** Arthur Ballance and Cecil Edward Arthur FitzMaurice, 8, Quality-court, Chancery-lane, London.

6400. **Improvements in and connected with the means of protecting electric conductors.** John Augustine Kingdon, 29, Marlborough-hill, St. John's Wood, London.

6416. **Improvements in ceiling roses for electric light fittings.** Francis William Ball and John Hugh Winter, 65, Chancery-lane, London. (Complete specification.)

6430. **Improvements in conduits for electrical conductors.** James Fulton Cumming and William Clymen Yawkey, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

MARCH 29.

6455. **Improvements in apparatus for indicating and recording electric supply.** William Thomson (Baron Kelvin), 154, St. Vincent-street, Glasgow.

6509. **Improvements in apparatus for electrically effecting the reproduction at a distance of graphic matter or designs matter, printed, stencilled, photographed, or otherwise produced.** Rupert Greville-Williams, 22, Southampton-buildings, Chancery-lane, London.

6473. **An improved composition applicable as a substitute for natural cork and for other purposes, such as an electrical insulating material.** Eugène Hermet, 55, Chancery-lane, London.

MARCH 30.

6536. **Improvements in apparatus for producing electrical effects on the stage.** Job Thomas Niblett, 20, Devonshire-road, Greenwich, London.

6545. **An improved electric arc lamp for optical lanterns and other purposes.** George Davenport, 19, John-street, Adelphi, London.

6546. **Improved application of telegraph and telephone circuits.** Samuel Dickinson Williams, Moorlinch House, Clytha-park, Newport, Mon.

6557. **Improved apparatus applicable to the working of electric or lime lights for theatrical purposes.** Samuel Vincent Evans, 4, St. Ann's-square, Manchester.

6565. **Improvements connected with the electrolytic production of alkali and chloride from sodium chloride solution and other substances.** Harry Tee, 8, Quality-court, London.

6575. **Improvements in apparatus for charging portable electrical accumulators or batteries.** Alfred William Bennett, 323, High Holborn, London.

6586. **Electric pneumatic action for organs.** Arthur Price, 162, Market-street, Birkenhead, Ches.

SPECIFICATIONS PUBLISHED.

1894.

4647. **Electric lighting.** Burrell and Fowkes.

4911. **Electric supply apparatus.** Mordey.

5003. **Regulating electric motors.** Aldridge.

5375. **Electromotors.** Statter.

6975. **Battery plates or electrodes.** Smith and Wright.

8317. **Telephone switches.** Lake. (Antwerp Telephone and Electrical Works.)

8823. **Transmitting signals through telegraph lines, etc.** Dearlove.

14246. **Electrical distribution.** Scott.

1895.

1526. **Electric conduit.** Mathers.

NOTES.

Algiers.—The Municipal Council of Algiers have under consideration a proposal to introduce the electric light for street illumination.

St. Pancras Electric Lighting.—A long article on this subject appeared in last week's *London*. It contains a good many inaccuracies.

E.P.S. Batteries.—A new catalogue has been issued by the Electrical Power Storage Company, Limited, with which we shall deal in a future issue.

Electric Crane.—Tests have been made at Havre of the electric crane which has been erected at the Vaubin Dock. The experiments left nothing to be desired.

Electric Lighting in Bombay.—A lecture on electric lighting has been delivered at Bombay by Dr. Kavaria, apparently with an eye to winning over the municipal councillors, who were specially invited to be present.

Electric Lighting in Roumania.—The theatre at Braila, which is connected with the rooms of the Regal Club, is to be lighted electrically. The work has been entrusted to Messrs. Lehmann and Mann, of Berlin.

Lathes, etc.—We have received from Messrs. Koch and Co., 1, Charterhouse-buildings, E.C., an illustrated catalogue of the Triumph precision lathe and other tools for watch and clock makers, engineers, electricians, etc.

New Telegraph Line for the Shan States.—A telegraph survey party for a new line from the Southern Shan States to Kyang Chang, in the neighbourhood of the Siamese buffer State, has been ordered to begin work at once.

Lecture.—In connection with the electrical engineering classes which have been commenced at the Central Schools, Leopold-street, Sheffield, Mr. C. L. Eclair-Heath, Wh.Sc., has delivered a lecture on the application of electricity to industrial purposes.

Electric Lighting in Argentina.—The Intendente is preparing a message for presentation to the Consejo Deliberante, asking for authorisation for installing three new electric light stations for public lighting in various parts of Buenos Ayres.

Book Received.—Messrs. Longmans, Green, and Co. have published "Problems and Solutions in Elementary Electricity and Magnetism," by Messrs. W. Slingo and A. Brooker. This work embraces the South Kensington papers for the years 1885-1894.

Telegraph Hill.—On Friday last Telegraph Hill, Hatcham, was opened to the public as a recreation ground. The name of the hill has nothing to do with electric telegraphy, but was given to it because it was the site of a semaphore station in olden days.

Personal.—On Saturday, 6th inst., at St. Mary Abbotts, Kensington, Mr. W. B. Esson was married to Mrs. L. V. Fairfax. A reception was afterwards given at the Kensington Palace Hotel, De Vere-gardens, at which was to be seen a goodly sprinkling of electrical men.

Electric Transmission at Pilsen.—An electrical transmission plant has been installed in connection with the Ziegler pit of the Blattniz Coal Company, of Nürshau, near Pilsen. This is the first installation of the sort in this district. The work has been carried out by Messrs. Siemens and Halske.

British Association.—In response to a circular issued by the Mayor, Dr. J. H. Bartlett, a meeting was held at the Town Hall, Ipswich, on Friday last, for the purpose of making some preliminary arrangements for the reception of the British Association in September next. There was a large attendance.

The Leicester Station.—The central electric light station at Leicester will be formally opened on the 25th inst. by Mr. Alderman Lennard, chairman of the Gas and Electric Lighting Committee of the Town Council. Sir Courtenay Boyle and Mr. W. H. Preece have signified their intention of being present.

Telephones, Fire Alarms, etc.—The Private Wire and Telephone Installation Company, 110, Cannon-street, have sent us an illustrated catalogue, which contains a few of the best patterns, with prices, so that the public can form their own idea of the cost of private wires and telephone and electric bell installations.

The American Electrical Pool.—The Philadelphia correspondent of the *Times* states that the committees which are making arrangements between the Westinghouse and Edison Electric Companies at New York for "pooling" the patents, and so preventing ruinous competition, have practically completed their agreement.

Telephony in Austria.—In the course of last year 24 towns in Austria were provided with telephone exchanges. As regards interurban communication, nine new lines were brought into operation during the year. There are now altogether 47 interurban telephone lines in operation in Austria, having a total length of 2,643¾ miles.

The Madras Electric Tramway.—Highly successful runs, says the *Indian Engineer*, are being made on the Madras tramway from the power station up to the Custom House. The date of the opening of the line for traffic has not yet been settled, as this will greatly depend upon the time that conductors and drivers, who are now being trained, will take to learn their work.

Telephony in Mysore.—The Inspector-General of Forests having submitted a drawing illustrative of the position of the several telephonic lines proposed to be erected in the vicinity of the Keddahs in the Kadur and Shemoga districts, which has met with the approval of Government, the British Resident has been asked to obtain the sanction of the Government of India for the erection of the above telephonic lines.

Northern Society of Electrical Engineers.—The ballot for new members and associates on April 8 has resulted in the election of Messrs. A. F. Ellis, Corporation electrical engineer, Southport; F. W. Page, Clarendon-chambers, St. Ann's-square, Manchester; and J. Sambidge (of Messrs. J. H. Holmes and Co., Newcastle-on-Tyne) as members; and Mr. J. A. Ormerod (of Messrs. R. Haworth and Co., Salford) as associate.

Presentation.—The employés of the City and South London Railway Company have presented Mr. Thomas Jenkin, the general manager to the company, with a writing-table and an illuminated address in recognition of the services of Mr. Jenkin in obtaining for the servants of the company an interchange of travelling privileges on all the important railway lines in the United Kingdom. The presentation was followed by a concert.

Royal Meteorological Society.—At the ordinary meeting of the society to be held at 12, Great George-street, Westminster, on Wednesday, the 17th inst., at 7.30 p.m., the following papers will be read: "The Frost of January and February, 1895, over the British Isles," by Mr. F. Campbell Bayard, LL.M., F.R.Met.Soc., and Mr. William Marriott, F.R.Met.Soc.; and "Some Hints on Photographing Clouds," by Mr. Birt Acres, F.R.Met.Soc.

Digitized by Google

Cable Lines.—The Spanish Government has decided to order an enquiry to be made regarding the construction of a direct telegraph line between the French frontier and Cadiz, giving France direct and rapid communication with Senegal and South America. The cable with the Canaries is now restored. The steamer "Dacia" has left for Senegal to repair the cable between St. Louis and Pernambuco.

Electric Traction in Paris.—The First Commission of the Paris Municipal Council have adopted the conclusions of a report by M. Puch concerning a scheme for the construction of an electric tramway to serve the Montmartre district. This line, which it is proposed to lay down with underground conductors, will commence at the Cadet crossing, and will terminate at the Rue Championnet. The report has yet to be considered by the Town Council.

County Council Tramways Bill.—The Select Committee of the House of Commons presided over by Mr. Roby, resumed on Monday the consideration of the Bill promoted by the London County Council to obtain powers to work any tramways which have been or may be purchased by them. The chairman stated that the committee found the preamble of the Bill proved. They would require a clause giving the Board of Trade power to make by-laws for the Council.

Theory.—Mr. John West, ex-president of the Gas Institute, has been reading a paper before the Manchester Association of Engineers on "The Economical Lighting of Public and Private Buildings, Workshops, etc." He informed that body that with gas at 1s. 9d. per thousand, as at Plymouth, the cost of incandescent electric lighting would be about 11 times as expensive as incandescent gas lighting. Mr. West's paper should have been read to the Marines.

Stage-Lighting.—The new Theatres and Music Halls Committee of the County Council do not seem to be following quite in the steps of their predecessors. The present committee have simply ordered special arrangements to be made at Sadler's Wells Theatre in connection with the limelight tanks. It will be remembered that the last committee, on the other hand, when dealing with the South London Palace of Varieties, ordered the abolition of limelight and the substitution of the electric light.

Institution of Electrical Engineers.—In consequence of the exigencies of their building operations, the Council of the Institution of Civil Engineers have been compelled to place the whole of their premises in the contractor's hands, and no further meetings can therefore be held there for some considerable time. The Institution of Electrical Engineers have consequently obtained permission to hold the remaining three meetings of their session—viz., on April 25, May 9 and 23—at the Society of Arts, John-street, Adelphi.

Signalling through Space.—Prof. J. C. Bose, of the Calcutta Presidency College, who has been experimenting on this subject for some time past, has just succeeded in making some instruments by which extraordinary results have been obtained, says the *Indian Engineer*. Without any connection between the transmitting and receiving stations signals in the form of light, sound, and other phenomena have been reproduced, and even solid walls have not interposed any obstacle to the transmission of these signals.

South-West London Polytechnic Institute.—This institute, which is intended to serve Chelsea, Fulham, and neighbouring districts, is now almost complete. It is situated in Manresa-road, Chelsea. The gymnasium will be open in the course of a few weeks. The lecture-rooms, the schools for domestic economy, the art school, and the laboratories for physics and chemistry, will be ready before the autumn session and all the staff appointed. The polytechnic will be one of the best equipped in London, and is expected to be most successful.

Organised Science Schools.—Mr. Acland, M.P., Vice-President of the Council, on Friday last received a deputation at the Education Office from the representatives of the Association of Head Masters respecting the recent regulations which have been issued by the Science and Art Department with reference to organised science schools. The deputation consisted of Mr. A. Scott, South Shields, president of the association; Mr. W. Dyche, Halifax, secretary; and the Rev. George Towner, from the Carpenters' Company's Institute at Stratford.

Weights and Measures.—The London Chamber of Commerce have received a letter from the London County Council on the subject of the Bill promoted by the Chamber for legalising the use of metric weights and measures for export trade purposes. The Chamber are informed that the Council resolved at its last meeting to do all in its power to secure the passing of the Bill during the present session, and that meantime no instructions have been given to the Council's inspectors to interfere with the use of metric weights and measures in the execution of foreign orders, nor is there any intention to issue such instructions.

"The Dangers of Electric Mains."—This is the title of an article in the *Lancet* in which Major Cardew's reports on the Budge-row and Euston-road explosions are dealt. It is mentioned that "the Vestry of St. Pancras are enjoined, as was pointed out in the *Lancet* of March 9, to provide a through system of ventilation or means for the immediate escape of gas from their conduits and street boxes." This statement is rather misleading. A casual reader would suppose from it that the *Lancet* originated the ventilation recommendation last month, whereas Major Cardew's opinion to that effect was made public considerably prior to that time.

Telephone Charges in South Wales.—A meeting of the Newport Chamber of Commerce has been held at which Mr. Robjent called attention to the notice of the National Telephone Company that from March 1 the rates for trunk line communication between South Wales and Bristol and Birmingham would be doubled, and said he calculated that the change would result in an increased revenue to the company of about £3,000 per annum. He thought it was a gross injustice to the district, and proposed a resolution protesting against the unjustifiable alteration, and inviting the Bristol, Birmingham, Cardiff, and Swansea Chambers to co-operate. Mr. L. B. Moore seconded the motion, which was carried.

New Electric Traction System.—Mr. E. Lachmann, of Hamburg, has sent a communication to the Berlin authorities that he has devised an underground conductor system for electric traction which is both economical and safe. Messrs. Siemens and Halske, it appears have constructed at Charlottenburg an experimental line, a twelfth of a mile long, on this system, which has worked satisfactorily. An extension of the experimental line is to be made to demonstrate its capabilities. It is claimed that the system is as cheap as the overhead Thomson-Houston system. We take these statements from the *Elektrotechnischer Anzeiger*, of Berlin, which, however, does not mention what Mr. Lachmann's system actually is.

A Curious Telephone.—According to an American correspondent of the *Times*, a Standard Telephone Company, with branches all over the United States, has been organised by prominent capitalists of New

Digitized by Google

York, Chicago, and elsewhere to furnish a cheap telephone service by a new system. It has a capital of 360,000,000dol., with many subordinate companies. The chief parts of the company's telephone are said to be two pieces of cork and a piece of platinum, and it is further claimed that by its system a message can easily be sent from New York to San Francisco. The company proposes to furnish a telephone service for 25dol. a year. The new company has at its disposal great political as well as financial power.

Iron and Steel Institute.—The spring meeting of the Iron and Steel Institute will be held in London on Thursday and Friday, May 9 and 10 next, in the rooms of the Society of Arts. The presidential address will be delivered by Mr. David Dale, and the Bessemer gold medal will be awarded to Mr. H. M. Howe, the distinguished American metallurgist, who will contribute a paper on "The Hardening of Steel." Mr. Stead, of Middlesbrough, will contribute a paper of great practical importance on "The Effect of Arsenic on Steel"; Mr. Sergius Kern, metallurgist to the Russian Admiralty, will discuss the manufacture of armour-piercing projectiles in that country; Mr. Herbert Scott will communicate a paper on "The Iron Ore Mines of Elba"; and Mr. W. J. Keep, of Detroit, will contribute a paper on "Tests of Cast Iron."

Apparatus for Telegraphs, etc.—Mr. G. Straus, 130, Queen Victoria-street, E.C., has issued a new illustrated catalogue of apparatus and accessories for telegraphs and telephones. Among the apparatus referred to are a microphone installation for domestic use, comprising microphone, model of German G.P.O., receiver, automatic switch, call bell, push, and three terminals for working over distances up to 325 yards; microphone installation for domestic use, with carbon grain microphone, the remainder identical with the former; and a microphone installation for domestic use, comprising carbon grain microphone, spoon-shaped receiver, automatic switch, 3½in. call bell, push, and four terminals. A portable electric signalling apparatus with "Reform" bells is also a novelty. It is worked in connection with dry cells.

Commercial Education. — The secretary of the London Chamber of Commerce informs us that as a result of its experience, extending over the last five years, in securing the school training of youths under the Chamber's commercial education scheme, the council have found that one of the most useful inducements they could offer to schoolmasters, parents, and youths has been that afforded by the list of firms who, in filling vacancies in their offices, have consented, "other things being equal," to give a preference to holders of commercial education certificates. The existence of such a list (which at present comprises out of a membership of over 3,600, about 200 names) is found to be of great use to schoolmasters in inducing parents to allow their sons to be educated on the lines of the Chamber's scheme, in view of the likelihood of employment it holds out.

Electric Traction in Germany.—It is proposed to construct an electric tramway between Bullay and Prarbach.—Authority has been received for the construction by the local accumulator company of an electric tramway between Hagen and Eckesey. The accumulators of the company are, of course, to be used on the cars. Work is to be begun at once, so that the line may be ready by the summer. It is intended subsequently to build an electrical line from Kükelhausen to Haspe, which is to be completed this year. There is also a prospect of electrical lines being laid down to Schwelmer, Herdecker, and Dahler.—Work is to be commenced shortly at Munich in connection with the electric tramway from Färbergraben to the Isarthal railway station *vid* Sendlingerstrasse and Thalkirchnerstrasse. Provided no technical difficulties occur, the line should be opened by May.

Athens Exhibition.—Information has been received from the Foreign Office, through the Science and Art Department, respecting the industrial exhibition at Athens. Her Majesty's Consul at the Piræus reports that a permanent industrial exhibition has been organised by the Société Biotechnique at Athens, and will be officially opened on April 28 (April 16, O.S.). This exhibition, although intended only for native products, will be accessible to foreign exhibitors of such articles as may assist in the development of Greek industries. All expenses will have to be paid by the exhibitors, who will, moreover, have to pay a tax of two drachmas for each article worth 100 drachmas. Articles worth more will be charged half a drachma per hundred in addition. The committee of the exhibition undertakes to sell the exhibits at a commission of 5 per cent. The exhibition will be open each year from March 13 (March 1, O.S.) to July 12 (June 30, O.S.), and from September 27 (September 15, O.S.) to January 27 (January 15, O.S.).

Experiences of a Cable Steamer.—A Shanghai paper states that the Great Northern Telegraph steamer "Store Nordiske" met with very severe weather when on the way to Possiette Bay. The steamer was only about 50 miles from her destination when she encountered a strong northerly gale of typhoon force, accompanied by driving snow that prevented anything from being seen, and the cold was intense at the time, the thermometer indicating 40deg. of frost. Everything on deck was a mass of ice, and of course the steering gear was useless. In this helpless condition the steamer fell into the trough of the sea and was in danger of capsizing, and it was only by almost superhuman exertions that she could be kept going. When the gale moderated all hands were employed to clear the vessel of ice, it being estimated that there were 150 tons weight on board, and this arduous work occupied the crew two entire days. Photographs were taken of the "Store Nordiske" when the gale abated which gave an excellent view of the extraordinary circumstances in which she was placed.

New Mains.—At Tuesday's meeting of the London County Council the Highways Committee reported that they had considered a notice from the County of London and Brush Provincial Electric Lighting Company of intention to construct 42 transformer-chambers in the parishes of St. Luke and Clerkenwell. Nothing had occurred to diminish in any way the strong objection entertained by the Council to the space under the public thoroughfares being appropriated for the construction of transformer-chambers of large size; and the committee recommended that the Council formally disapprove the works. They had also considered a notice from the House-to-House Electric Supply Company of intention to lay mains in Marloes-road. These, which comprise both high and low tension mains, were approved of. Notices had been given by the Metropolitan Electric Supply Company of intention to lay mains in Charing Cross-road, Great Newport street, and Long-acre, on the north side of Dorset-street, in Cosmo-place, Little Ormond-street, and Queen's-square, south side. No objection was raised to the proposed works, but it was stated that the mains for Charing Cross-road should so far as practicable be laid in the subway there. A notice had been given by the Westminster Electric Supply Corporation of intention to lay mains in Davies-mews. The proposed works were approved of. A notice was received from the Vestry of Hampstead of intention to lay mains in High-

Digitized by Google

road, Kilburn. The Vestry is the undertaker under the order, and the Council has no power of approval or disapproval of works.

Institution of Junior Engineers.—At the meeting of this institution held at the Westminster Palace Hotel last Friday (5th April), the chairman, Mr. H. J. Joung presiding, a paper on "The Study of Alloys" was read by Mr. Walter G. McMillan, lecturer on metallurgy in the Mason College, Birmingham. The author gave an account of some of the recent researches of Roberts-Austen, Wright, Heycock, and Neville, and many others on the nature and constitution of alloys. He showed how some pairs of metals formed homogeneous mixtures, which might be kept for hours in a fused condition unchanged, whilst others rapidly separated into layers, and he described the influence of increasing proportions of a third metal upon the immiscible pairs. It was then shown how mixtures, uniform when fused, might give a non-homogeneous metal when solidified, which was explained by referring to the tendency to form "eutectic" alloys of definite composition, with lower fusing points than those of the metals used, so that one constituent after another crystallised out from the mass of fluid metal, leaving at last the eutectic alloy to solidify in the spaces around the separated solid particles. In conclusion, the author urged the necessity for precision and system in reporting results, and regretted the use of trade names which (even if in certain cases justifiable) were misleading to the lay mind and tended to produce great confusion in the literature of the subject, because there was no certainty as to the meaning of an author who merely employed such a term without giving an analysis of the mixture. As knowledge advanced, engineers would require to know the composition of the alloys in the market that they might be able to discriminate for themselves their fitness for the required purpose.

Obituary.—The death took place on Sunday last of Mr. John Henry Greener, electrical engineer, at Herne Hill, in his sixty-sixth year. He was born at Etherley, Durham, in 1829, and began his career in London on the Blackwall Railway in 1843, and was there first connected with the electric telegraph. In 1847 he entered the service of the old Electric Telegraph Company. In 1853 he was appointed by the company to construct the first line of telegraph erected in Norway; and two years later he went to Denmark to construct the telegraphs on the Royal Danish railways. Shortly after his return, says the *Times*, he proceeded to Ireland to report upon the state of the lines between Dublin and Galway, for the purpose of establishing direct communication with the Atlantic cable. At the end of 1860 he was selected by the Secretary for India to report on the condition of the Turkish telegraph lines in Asia Minor connected with Constantinople; for the Red Sea cable had temporarily failed, and it was considered advisable that we should have alternative means of communication with India by telegraph. Mr. Greener was despatched to Bombay in 1862 to accompany an expedition for taking soundings and selecting landing-places for the proposed cable from Kurrachee to Fao, at the head of the Persian Gulf. Mr. Greener having constructed land lines from Bagdad to the latter place, and the cable having been successfully laid thence to Kurrachee, his work in the East terminated, when communication along this route between England and India was completed in 1864. On returning to England, he became inspecting engineer for stores to the India Office. He was also appointed in the same capacity as engineer for the Crown Agent for the Colonies and for the Agent-General for the Cape of Good Hope. He severed his connection with the India Office a few years ago, but kept his position at the Colonial Office until his death. Among members of his profession Mr. Greener was always regarded as one of the most able of practical telegraph engineers.

Kingdon's System of Laying Electric Mains.—Systems of electric mains in which the conductors, whether insulated or bare, are drawn into iron or other pipes or laid in conduits, are open to the objection that an empty space is left round the cables or conductors, where an explosive mixture of air and gas may accumulate. Armoured cables are not open to this objection, but as the armouring can be easily penetrated by a pick, additional protection is necessary. In the Kingdon system of laying electric mains these difficulties are overcome in a simple manner. The conductor, insulated with indiarubber, paper, or other material, is thoroughly protected against mechanical injury by an iron or steel channel of U-shaped section placed above the cable. The peculiar form of the exterior of the channel causes a pick or other tool to glance off to one side without penetrating the iron. The interior of the channel is of such shape as to approximately fit the cable. Below the cable is placed a strip of iron or wood, which is moulded to fit the cable. This is forced upwards within the channel, so that it is not liable to displacement or injury. Joints in the channel are covered by means of iron sleeves or slips, which serve also to secure the strip in place. For continuous currents a single-stranded cable may be employed. For alternating currents, two cables laid side-by-side, or a concentric cable, are used. Concentric or triple-concentric cables are also employed in the case of two or three wire continuous-current systems. Where branches from the mains are required cast-iron junction-boxes are inserted, which are filled with solid insulating material after the joints are made and insulated. Where a branch is not immediately but may subsequently be required, a short length of channel is placed, which can be easily removed by driving back the sleeves at either end for the substitution of a junction-box. Bends can easily be arranged for places where the cables have to pass round corners or to dip downwards so as to avoid obstruction. Mr. J. A. Kingdon, 29, Marlborough-hill, N.W., is the inventor of the system.

Lecture on Electric Traction.—At the Croydon County Polytechnic, on the 8th inst., Mr. C. H. Yeaman, A.Inst.E.E., delivered a lecture on "Electric Traction, with Special Reference to Traction on Common Roads." The lecturer opened his subject by a brief discussion of the reversibility of the dynamo machine. He then proceeded to describe the three types of electric traction systems—the conduit or underground, the trolley or side rail, and the accumulator or self-contained car. The different proposals which have been made from time to time on the subject of tramways were reviewed, and some reference was made to the application of electrical power to railways for long-distance and high-speed traction. The Heilmann locomotive and the Boynton bicycle car were instanced as being two developments along different lines, while many of the English, Continental, and American lines were incidentally dealt with. The details of electric traction work and the difficulties which have in the past beset it were also the subject of notice, but it was shown how electrolytic troubles were got over by rail bonding or electric welding, but powerful brakes were obtained by an adaptation of the principle of Foucault's disc, and how the fender question was tending in America. In the second portion of the discourse Mr. Yeaman drew special attention to accumulator cars running on rails, and also those adapted for ordinary roads. The leading features of accumulators of different types were gone into, samples being before the

Digitized by Google

audience, and then the use which had so far been made of the storage system was illustrated by references to the Birmingham and other tramways. The common road vehicles of Garrard, Cummings, Arnold, Radcliffe Ward, Bersey, and others were illustrated, and their peculiarities dwelt upon. The lecturer regarded the future of self-contained vehicles as being a promising one, and brought his discourse to a close by a short consideration of the sanitary and commercial aspects of the problem. The lecture was copiously illustrated by experiments and lantern projection, and was received with great appreciation by a large audience.

Code Cablegrams.—On Monday, in the House of Commons, Mr. Henniker Heaton asked the Postmaster-General whether he had observed that the new official vocabulary for code cablegrams, prepared by the International Telegraph Office at Berne, was objected to on the grounds, among others, that it contained words identical in signals with other words, words with only one signal difference from other words, words with only one letter difference from other words, words with first letter's signals dangerously like others, and words representing names of articles of commerce, coins, numerals, and firms, and localities; and whether this vocabulary could still be amended and extended, or whether it was binding as it stood on the public; and, if amendments would be accepted, whether he would suggest that the official compilers of it should consult with two or more British telegraph experts and with the Associated Chambers of Commerce with a view to removing the defects complained of. Mr. A. Morley stated that he was aware that objections had been raised on the grounds mentioned, but he might remind the House that the new vocabulary did not come into force until January 1, 1898. There was ample time for consideration in the interval, and the matter was receiving careful attention. Being questioned by a Liverpool correspondent in regard to the prospective compulsory telegraph code for all European telegraph offices, Mr. J. Henniker Heaton, M.P., wrote: "In the *Times* of the 16th ult. you will find the Postmaster-General's answer to a question of mine on this subject, his view being that our hands are tied by our connection with the Postal Union. This is only another proof of the recklessness with which the interests of British trade are signed away by our amateur diplomatists at the Post Office. The cables are in British hands; the bulk of the world's trade in which cabling is required is in British hands; yet British merchants are not consulted in the matter. It is well known that a code cannot be too extensive, since the larger the number of words the greater is the choice of expressions denoted by them. Accordingly, hitherto merchants have been allowed to take words from eight appointed languages, and many of them have been at enormous expense to prepare codes from these languages embodying upwards of half a million words. Now, the official vocabulary only includes between 200,000 and 300,000 words, so that the range of expression is greatly restricted, while the money spent on private codes is henceforth a great loss. I say nothing of the objections to the official list arising from the use of similar pairs of words, the want of an index, etc. My contention is that, if there is to be an official list, it should include all suitable words in the eight authorised languages, or that, in the alternative, private codes drawn from these languages should be admitted. Anything less would amount to a serious diminution of the utility of cables, and a corresponding injury to British trade. In my opinion, a deputation should wait on the Postmaster-General to remonstrate against the imposition of the official list; above all, for extra-European cablegrams."

The Falls of Foyers.—We have previously announced that a scheme is on foot for the utilisation of the Falls of Foyers, in Inverness-shire, in connection with an electric transmission plant to be used for the production of aluminium. This proposal has just caused a somewhat violent article in the *Daily Chronicle*, which on Monday, under the heading of "The Vandal in Scotland," came out with the following: "Are the Falls of Foyers to be swept off the face of the earth? This is the question which in another form came up before the Inverness District Committee on March 8, and which they wisely remitted to the County Council. As Sir George Trevelyan casts the responsibility on the same body, the county councillors of Inverness-shire must look to their laurels. The Fall of Foyers is undoubtedly the finest waterfall in the British Isles, and many who have wandered far in other lands still revert to it as of surpassing beauty. We will not attempt to rival the many poets who have described these falls; nor can the painter or photographer do justice to their picturesqueness. For their distinctive feature, the masses of spray in which on sunny days a complete circle of rainbow can be seen, eludes alike the brush and the camera. To be known, therefore, they must be seen; yet, if certain persons have their way, they will never be seen more. A body, calling itself the British Aluminium Company, has arranged to purchase the estate of Foyers, on which the falls are situated, and proposes to use the water power to produce electricity, and thereby to extract aluminium from clay. For this purpose it plans to deflect the River Foyers from its present channel, and lead water in an 8ft. pipe to the shores of Loch Ness. Now, by a slight additional expenditure they might get their water power without damaging the falls, but will they do so? The plans of the company involve the turning aside of two roads in Strathherrick, and for this they require the sanction of the County Council. The agents of the company have been lavish in their promises of remunerative employment and improved trade—indeed, they hold out the prospect generally of a golden age in the near future if the inhabitants will but banish their consideration for lovely scenery, and permit prosaic business men to work their money-making schemes. Probably an appeal to the æsthetic feelings of the district committee might have been quite in vain had not the chairman tactfully pointed out that the financial state of the company has been subjected to public criticism. The company is accordingly to lay its plans before the County Council at its next meeting, and that body has in its power—(1) to stop the company completely; (2) to leave it an entirely free hand; or (3) to exact from it substantial guarantees that its operations shall not injure the natural beauty of the country. In the interests of a perfectly impartial consideration of the matter, it is perhaps unfortunate that most of the officials of the County Council are financially interested in the company; that one of the chief Inverness journals is the property of its local agent; and that, whereas the company are carrying on an active canvass, we hear of no organisation on the other side. The danger therefore is felt to be that the wider question of preserving a piece of beautiful scenery which is of national importance may be sunk in the smaller one of an accidental commercial undertaking which chooses to find the waters suitable for its private concerns—a very real danger, seeing the decision lies with a local body, probably biassed, with which local interests must be supreme. It is, moreover, by the merest chance that any public body has anything to say in the matter, though if law were, as we are sometimes told it is, the expression of use and custom, the Falls of Foyers belong to the public."

THE THEORY OF ALTERNATING CURRENTS.—III.

BY A.INST.E.E.

§ 7. **Simple Ideal Alternator.**—An alternating current is one which periodically varies in magnitude and direction, fluctuating alternately in positive and negative directions at a rapid rate, thus forming a succession of undulating waves. Such a current is set up by a rapidly alternating E.M.F., and to understand these currents we must investigate the nature of alternating E.M.F.'s, and to simplify matters we shall neglect any inductance which may be present in the circuit. Our starting point is Faraday's discovery made in 1831—*i.e.*, that an E.M.F. is set up in any part of a conductor, whenever such portion cuts lines of force, so that the number of lines of force looped with the conductor increases or decreases.

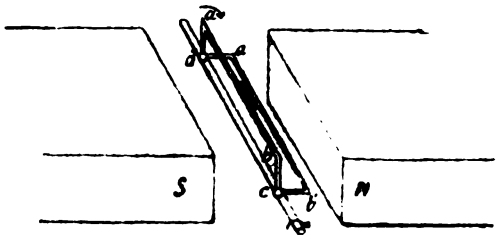

FIG. 3.

To take a particular case, let us consider a single rectangular coil of wire placed in a uniform magnetic field, and capable of rotation about one of the long sides as an axis, which is horizontal and perpendicular to the direction of the lines of force, as shown in Fig. 3, which are horizontal. It is evident that when the plane of the coil is vertical—*i.e.*, perpendicular to the lines of force, as at *a*, *b*, *c*, *d*—it is enclosing the maximum number of lines of force. By moving it through 90deg. to the position a^1, b^1, *c*, *d* the plane of the coil is now parallel to the lines of force, and the coil encloses the minimum number of lines, which is zero. In other words, the rotation through 90deg. is equivalent to emptying the coil of lines, to do which the coil has cut the maximum number of lines of force. By rotating the coil through the next quadrant the plane of the coil is again vertical, and it again encloses the maximum number of lines—that is, the movement through the second quadrant is equivalent to filling the coil with lines of force from the opposite side. The result of this cutting the lines of force is to make the side *a b* of the coil the seat of an E.M.F., the direction of which is the same during the motion through the two quadrants. On continuing the rotation of the coil, it is again emptied and filled as before, and the direction of the resulting E.M.F. is reversed. This is the simple physical aspect of the problem, and we must now consider the magnitude of the E.M.F. induced, which is proportional to the rate at which the magnetic flux is cut. As we shall see presently, the E.M.F. varies harmonically, and for this reason we shall now explain the elementary principles of harmonic motion.

§ 8. **Simple Harmonic Motion.**—When a point, P, describes a circle with uniform velocity, the point *p*—the foot of the perpendicular from P on a diameter, as $A\,O\,A_1$ in Fig. 4—will have a to-and-fro motion along $A\,O\,A_1$, the velocity of which will be variable. The motion of *p* is typical of a certain kind of motion of frequent occurrence in physical phenomena, and which, in fact, lies at the root of all wave movements. Technically, it is known as *simple harmonic motion*, and it is important that we should be able to determine the velocity of *p* relatively to that of P. Let V be the velocity of P, which we know to be uniform Now, circular motion may be produced by two simple harmonic motions in directions at right angles to one another; in other words, two simple harmonic motions taking place simultaneously along $A\,O\,A_1$ and $B\,O\,B_1$ will produce circular motion equivalent to that of P. Then by obtaining the component of the motion of P along $A\,O\,A_1$, we shall obtain the actual motion of *p*. If the velocity of P be assumed to retain the direction it has for the instant it is at P—that is, along P Q, which is the tangent to the circle at P—then by denoting the value of V by the length P Q, the resolved portion in the direction $A\,O\,A_1$ will be denoted by the length $P\,p_1$ to the same scale as P Q is drawn. Now, from the geometry of the figure it is obvious that the angle $P\,Q\,p_1$ is equal to θ, and $\sin\theta = \frac{P\,p_1}{P\,Q} = \frac{P\,p_1}{V}$; that is, $P\,p_1 = V \sin\theta$, and this is the velocity of *p* in the direction $A\,O\,A_1$, in terms of the velocity, *v*, of P and its position. Since the velocity is proportional to the *sine* of the angle subtended by the arc described by P, we see that the velocity of *p* varies for every position of P—that is, the velocity of *p* is not uniform. Now, the value of sin 0deg. and sin 180deg. is zero, consequently

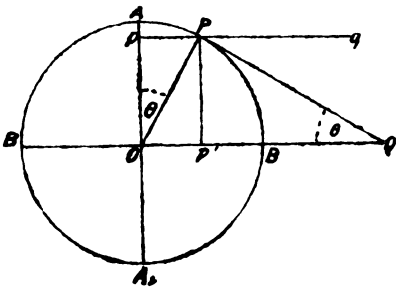

FIG. 4.

the velocity of *p* is zero at A and A_1; but the value of sin 90deg. is unity, therefore the velocity of *p* at O is equal to the velocity of P, and this is its maximum value. In other words, *p* begins to move slowly at A, increases to its maximum at O, and decreases at the same rate until it reaches A_1, where its velocity is zero. Immediately afterwards *p* moves backwards along the same diameter, and calling the motion from A to A_1 positive, the motion from A_1 to A will be negative, from which we see that the direction of motion of *p* is reversed twice every revolution of P.

The results thus deduced may be conveniently represented graphically. We have seen that the velocity of *p* is V sin θ, and if the radius of the circle be taken to denote the value of V, the velocity of *p* at $p = O\,P \sin\theta = O\,P \times \frac{P\,p}{O\,P} = P\,p$, since $\sin\theta = \frac{P\,p}{O\,P}$. Therefore, for every position of P the velocity of *p* is represented by the length of the perpendicular from P on $A\,O\,A_1$. In Fig. 5, the circumference of the circle is divided into a number of equal parts, and perpendiculars let fall from each on $A\,O\,A_1$. In our case we have taken 24 parts, but only those in the upper half are shown in the figure. Any number of parts, however, may be taken, but it is advisable that the points A, B, A_1, and B_1 coincide with four of the divisions. Since the velocity of P is uniform, the time taken by *p* to move from A to p_1, p_1 to p_2, etc., will be the same, and the lengths of the divisions along $A\,O\,A_1$ indicate how the velocity of *p* varies, whilst the lengths of the perpendiculars, $P_1\,p_1$, $P_2\,p_2$, etc., denote the velocity of *p* for the different positions of P—*i.e.*, P_1, P_2, etc.—showing at a glance how the velocity of *p* increases until O is reached, and then decreases.

§ 9. **Sine Curves.**—The graphical representation given in Fig. 5 may very conveniently be extended so as to show at a glance the undulating character of the velocity of *p*. The method adopted is very simple, and we shall very frequently make use of the resulting curve, which is constructed as follows: The left-hand portion of Fig. 6 consists of the last figure reproduced, with the diameter $A\,O\,A_1$ produced indefinitely to the right. This line serves the purposes of a zero line, and is divided into a number of equal parts, A p_1, p_1, p_2, etc., to represent equal intervals of time. From each of the divisions, p_1, p_2, p_3, etc., perpendiculars are erected equal in length to $P_1\,p_1$, $P_2\,p_2$, etc., taken from the figure on the left; consequently each of these perpendiculars represents the sine of the angle through which P has moved in the time corresponding to the interval of time denoted by p_1, p_2, etc. For instance, the perpendicular $P_2\,p_2$ measures sin θ, θ being the angle moved through by P in the time denoted by p_2. The

Digitized by Google

method of projecting the perpendiculars as shown by the dotted horizontal lines is the most convenient method of getting the points P_1, P_2, P_3, etc.

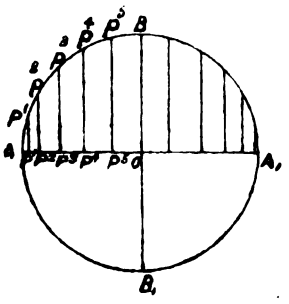

FIG. 5

By drawing the curve through A, P_1, P_2 . . . to A_1 and continuing it to A below A O A_1, we get a *true sine* or *sinusoidal curve*, which expresses graphically the fact that the successive values of the heights of consecutive points on the curve from the zero line vary as the sine of the angle through which the point P has moved. Such a curve can always be constructed when a quantity varies according to a simple harmonic law. The shape of a sine curve depends upon two quantities, which are analogous to the velocity of P and the radius of the circle, or, in other words, to the two components of wave motion.

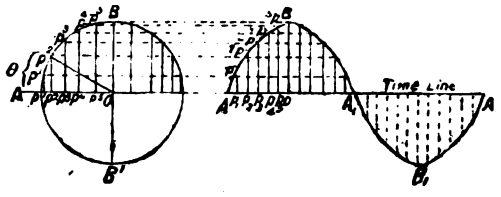

FIG. 6.

§ 10. **Alternating E.M.F.'s.**—The student will now be in a position to see that the motion of P corresponds to the motion of the side *a b* of the rectangle, *a*, *b*, *c*, *d*, shown in Fig. 3 above, especially if he imagines himself to be taking an end view of the rectangle rotating in the magnetic field between N and S. In fact, the circle in Fig. 4 is the path traversed by the corner *b* of the rectangle, whilst P, B, A_1, and B_1 are positions taken up by *b* during one revolution. Now, to get the value of the E.M.F. induced, we must determine the rate at which *a b* cuts the lines of force of the field. To do this we denote the depth of the field by the length, A O, and the breadth by the length, *a b*, of the rectangle; and as the length *a b* is constant, it is obvious that the number of lines of force enclosed by the rectangle in any position whilst rotating is proportional to the length *p* O, which, as we have seen, varies for every position of *b*—in other words, the lines enclosed is proportional to cos θ. But the rate at which the lines are cut is analogous to the velocity of the point *p*, which, as we have seen, is proportional to sin θ, where θ is the angle moved through by the rectangle from the vertical position.

Then if H = the number of lines of force per square centimetre, and A = the area of the rectangle, *a*, *b*, *c*, *d*, in square centimetres, the total number of lines enclosed by the rectangle when in the vertical position = H × A; and from what has been said previously, it is clear that the number cut whilst the rectangle moves through the angle θ is H . A sin θ, and this is a measure of the E.M.F. induced at the instant the rectangle makes an angle θ with the vertical. Let N = H × A, then $E_\theta = N \sin \theta$ (absolute units).

A more general way of expressing the instantaneous E.M.F. is to state θ in terms of the unit of angular velocity. As is well known, the radian, the unit of angular velocity, is the angle subtended by an arc equal to the radius. Since the circumference of a circle = $2\pi r$, it is evident that one revolution is equivalent to describing an angle of 2π radians. The symbol ω usually denotes the number of radians described in unit time. Therefore, if T be the time occupied in one revolution, and *t* the time taken to describe the angle θ, it is obvious that

$$\theta = \omega t = 2\pi \frac{t}{T}.$$

In an alternator, however, the speed is usually such that it makes *n* revolutions per second, and if the coil consists of S turns, then the value of the E.M.F. induced expressed in volts after a short time, *t*, has elapsed since the coil left the vertical position, will be

$$E_1 = \frac{2\pi}{T} S N \sin \frac{2\pi t}{T} \div 10^8 \quad . \quad . \quad . \quad (1)$$

since one volt = 10^8 absolute units; but $\frac{1}{T} = n$, therefore (1) may be expressed as follows:

$$E_1 = 2\pi n S N \sin 2\pi n t \div 10^8 \quad . \quad . \quad . \quad (2)$$

or, $$E_1 = D \sin 2\pi n t,$$

where $D = 2\pi n S N \div 10^8$.

ELECTRIC MAINS IN PARIS.

BY A. MONMERQUE.

(Continued from page 393.)

There was in use in another section of Paris a system of mains now condemned by experience—*i.e.*, the system of iron hooks for supporting insulated cables. In this section the mains were indiarubber covered, laid in cement concrete culverts, being supported on iron hooks built into them, as shown in Fig. 8. These iron supports were enamelled, and it was hoped to prevent them rusting by this process. It did not do so, and in a short time the iron was rusted everywhere. The rust of itself did not matter, but its action on the insulation became serious in reducing the insulation resistance of the cable.

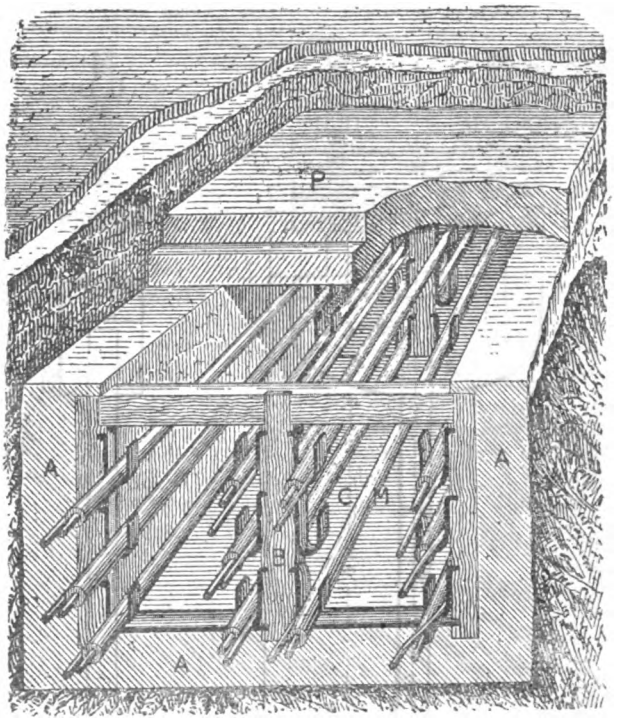

FIG. 8.

The specification of the cables was as follows: A tinned copper conductor, covered with one coating of pure rubber, one of an indiarubber mixture 2mm. thick, and two of rubber tape, the whole vulcanised and braided, and then dipped in bitumen. After laying, the insulation resistance of these cables was very satisfactory, but after a year's work the insulation resistance of the individual sections of the mains tried singly did not average more than 2,000 ohms per section, the maximum voltage of distribution being 220 volts. The minimum insulation resistance per section

Digitized by Google

allowed by the rules issued by the municipal authorities on September 15, 1893, was 242,000 ohms.

In the extensions of the network the engineers immediately abandoned this system in favour of armoured cables of the same type as used in the section of the Place Clichy. Little by little the faults got worse, till it was decided to condemn the iron hooks. After having clearly proved the inherent faults of the enamelled iron as supports for the cables, the engineers tried several palliatives, such as putting a rubber shield between the iron and the cable as a protection. It was finally found necessary to replace the hooks with another system of support. This radical decision was come to in order to avoid as much as possible the continued opening out of the trenches under the public footpath.

It was necessary to adopt a tried system which did not necessitate the opening of the conduits for purposes of supervision. With this idea they simply used insulators similar to those adopted when the cables are bare. So an insulator was employed of the type shown in Figs. 9 and 10.

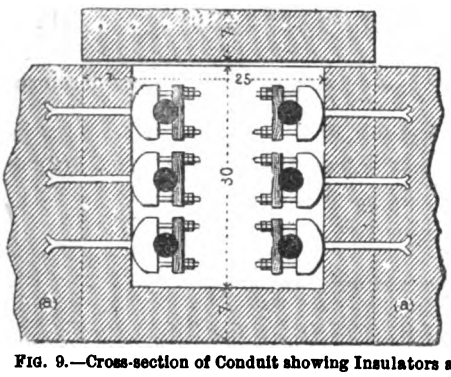

FIG. 9.—Cross-section of Conduit showing Insulators and Insulated Cables.

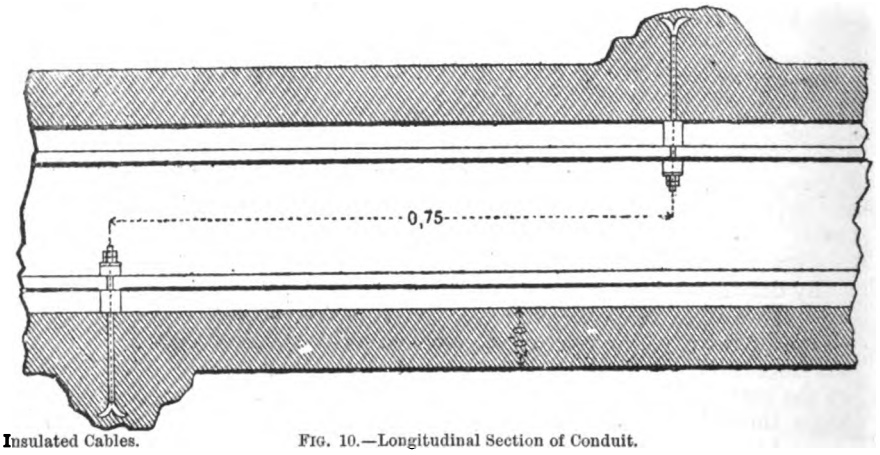

FIG. 10.—Longitudinal Section of Conduit.

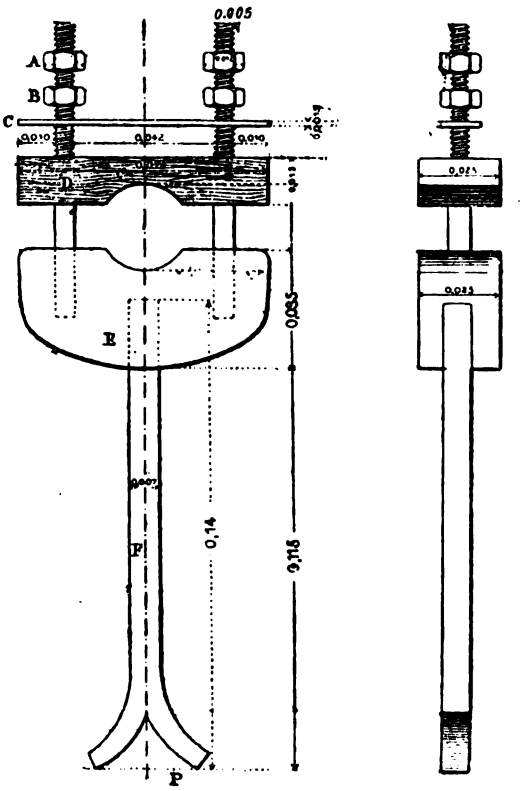

FIGS. 11 AND 12.—Details of Insulators.

The insulators were mounted on iron stems 6in. long, being sealed in with sulphur, and the other end cemented in to the sides of the conduits. These sides were originally only $2\frac{3}{4}$in. thick, and had to be increased, as shown by the dotted lines, to double this thickness, to give the necessary support. Figs. 11 and 12 show the details of the insulator. The part E is made of smooth porcelain with rounded grooves to hold the cables. In this porcelain two iron screws are cemented, by means of which cross-pieces of wood, D, clamp the cable in place. The insulators cost $5\frac{1}{4}$d. each. When a type of conduit as illustrated is used having a breadth of 10in., and containing one feeder and one set of distributing mains on the three-wire system, the insulators are placed 2ft. 6in. apart on opposite sides, so that the cables are supported every 5ft. The actual cost per yard of the transformation was as follows:

	s.	d.
Labour, etc.	3	$7\frac{1}{2}$
Cement, etc.	1	10
Insulators	1	10
Sundry items	0	$8\frac{3}{4}$
	8	$0\frac{1}{4}$

In these charges the cost of breaking up the streets and of repairing them is not included.

It will be seen that the cost is small compared with the great inconvenience of repeatedly opening out the conduit, or at least of abandoning the conductors and relaying an entirely new network, which would have been necessary had not this method of overcoming the difficulty been adopted. We are able now to give the results obtained with this system compared with those obtained when the iron hooks were employed. The insulation resistance of the network was taken in sections every Monday. The conductors were so arranged as to be readily uncoupled for testing a three-wire system, being used at 220 volts. The supply was thus only interrupted during the short time the test was being made. When testing a feeder, the network was supplied for the time being by the other feeders. The tests were taken with a small ohmmeter, with a hand-driven generator, at about 200 volts. The ohmmeter indicated up to five megohms; above that value the exact insulation resistances did not matter.

The results found are tabulated below in a form which shows clearly the improvement effected by the suppression of the iron hook supports. The figures show that the insulation resistance was improved by the new insulators to about 250 times its original value for the negative wire, 18 times for the zero wire, and 16 times for the positive wire. The insulation of all three wires is above 242,000 ohms, which is the minimum allowed by the regulation for this section. It is to be remarked that the insulation resistance of the negative wire is always less than that of the positive. This seems to be an invariable rule whatever the nature of the network.

Date.		Sub-main. Length.	Insulation to earth. Ohms.	Insulation to earth. Per mile.	Remarks.
May 19	−	66 yards	2,000	75	With iron hooks.
	0		60,000	2,260	
	+		300,000	11,300	
June 12	−	66 yards	500,000	18,800	With insulators.

After having indicated the system of mains which experience has condemned in Paris, it will be interesting to review the divers systems in use and now being laid in the different sections, and we shall proceed to discuss each system separately.

(To be continued.)

THE CAIL-HELMER SINGLE-BEARING DYNAMOS.

We are able this week to further supplement the information we gave in our last issue about this interesting type of dynamo.

The accompanying table is sufficient to enable all makers of dynamos to compare their designs with those used by the Cail Company in Paris. It will also give useful information as to the efficiency allowed by the French engineers and accepted by the general public.

LIST OF DETAILS OF CAIL-HELMER DYNAMOS.

Number of design	H_4.	H_5.	H_6.	H_7.	H_8.	H_9.
Useful power, in kilowatts	1·55	2·5	3·8	5	7·6	10
Difference of potential, in volts	115	115	115	115	115	115
Current, in amperes	13·5	22	33	44	66	87
Speed, revolutions per minute	1,550	1,500	1,420	1,330	1,170	1,000
Circumferential speed, feet per minute	3,570	3,640	3,670	3,820	3,830	3,840
Armature core, outside diameter, in inches	8 8	9·3	9 9	11	12·5	14·6
Depth of core, in inches	·95	1·11	1·2	1·35	1·53	1·9
Length, in inches	1·6	2·05	2·4	3	3·65	4·5
Number of active wires	1,944	1,200	1,104	743	642	626
Current density in amperes, per square inch	3,660	3,550	3,350	3,220	2,900	2,580
Flux in C.G.S. lines	257,000	421,000	480,000	790,000	990,000	1,183,000
Loss in copper resistance in armature, watts	199	254	341	430	607	753
,, ,, in magnets, watts	61	78	104	132	186	213
Hysteresis, Foucault, and mechanical losses, watts	400	511	687	865	1,225	1,517
Total losses, watts	660	843	1,132	1,427	2,016	2,483
Electrical efficiency, per cent.	85·7	88·5	89·7	90	90·5	91·2
Commercial efficiency, per cent.	70 2	75·2	77·1	78·1	79	80·2

We would remark that such a full list of essential details has never been published by any English firm of electrical engineers.

SOME METHODS OF COLLECTING THE ENERGY IN ELECTRIC RAILWAYS AND TRAMWAYS.*

BY M. HOLROYD SMITH, MEMBER.

The first principles governing the use of electricity as the motive power for tramways and railways are now so well understood that no reference need be made thereto, except so far as occasion requires in dealing with the subject under consideration. The success or failure of an enterprise often depends upon an apparently insignificant detail. The subject-matter of this paper is an example. Perhaps few approaching it for the first time would realise its importance until they come face to face with the difficulties involved. Conditions pertaining to the collector may be summarised as follows: (1) provision for making and maintaining contact between the motor on the car and the supply conductors, whether that be overhead or underground; (2) the avoidance of damage, either electrical or mechanical, should the collector become blocked or the car leave the track; (3) the collector must be able to take the points at turn-outs, and traverse crossings without fouling them or short-circuiting; (4) the collectors must be so insulated as to be safe to handle, and avoid leakage; (5) no danger or damage to the public must result from their use; (6) they must be simple and durable, and the working parts must be cheap to renew.

Perhaps the most interesting way of treating this subject would be chronologically, tracing its developments, and that shall be done as far as possible whilst classifying the different types. In the time available it will be impossible to enumerate all that has been done; the selection made must therefore be regarded as typical. In the first example of electric traction without carrying a battery on the car, made by Thomas Hall, of Boston, U.S.A., in 1852, where the supply current was taken by one rail and returned by the other, and in the subsequent examples on a larger scale by Dr. Siemens in 1879, and afterwards by Volk, in Brighton, the wheels, of course, had to be insulated one from the other or else they would "short-circuit" through the axles, and they obviously formed a simple and ready means of collecting the current; but considerable difficulty arose in gathering the current from the wheels owing to the unavoidable collection of dirt. It is no use entering into any details of the brushes, discs, clamps, etc., tried, because the "go-rail come-rail" system of working tramways is not likely ever to be of practical utility. This was soon discovered, though slowly admitted, and the centre rail or conductor bar came into use. The early designer evidently had dynamo brushes in his mind, but difficulties arose in reversing the car—the brushes, which would stroke the bar easily when running one way, would double up if it were attempted to run them the other, and any surging or springing of the car would cause disarrangement. Another method was to use sliding shoes made of cast iron, and held together by the spring bolts, which are easily attached and removed, and accommodate themselves to any inequality of the bar, and, together with flexible pulling cords, permit the slider to travel as easily in one direction as the other. Both these plans require special arrangement of the conductor bar at points and crossings. The simplest form is that adopted in the City and South London line and elsewhere, where cast-iron curved flappers rest by their weight upon the conductor bar. As these still continue to be used, they must be found to act reasonably well, but it is obvious that should a fault or obstruction occur in the conductor bar (say, where it is replaced by wood at rail crossings), and the leading flapper fall, it would at once jam and cause a smash. It is a matter of surprise that a safer method has not been devised. Another example of collecting from a plain bar is that employed on the Portrush and Bushmills line. The conductor there is a T-iron forming a railing about 2ft. high on one side of the road; an arm projecting from the side of the car has a carriage spring at the end; on the underside of the spring is a shoe, which slides upon the rail. This works fairly well, but the inevitable dithering action of the shoe is objectionable. All these collectors slide on the bar, and it is natural to ask, Does not considerable wear and tear result, and could it not be avoided by rolling contact? Before discussing the relative merits of the two methods it will be well to give further examples.

The first underground electric channel—viz., that laid in the grounds of Moorfield, Halifax, in 1883—ran on four wheels, one side being insulated from the other, because one side collects and the other returns the current. In addition to the wheels, sliding shoes were provided. These shoes are free to rise and fall. This worked sufficiently well for experimental purposes, but was not considered good enough for work on a large scale, hence more elaborate designs were got out. First, a steel plate or plough is provided to pass upward through the channel slot to

* Paper read before the Northern Society of Electrical Engineers, April 8, 1895.

Digitized by Google

the road surface, and the copper conductors are insulated and embedded in this plate. Instead of the sliders collector discs are used, and these are set at an angle with the line of movement, the consequence being that a combined rolling and sliding action was secured. A collector on this principle was used on the first electric locomotive tried on the Manhattan Elevated Railway, New York. The device may be accepted as the simplest way of making roller collectors useful, but experience shows that their use is to be avoided, because a roller gives very little surface contact for gathering the large current necessary for traction work. The wheels roll over any dirt that may be on the conductor bar, thus breaking contact and "sparking," and this excessive sparking causes more wear than the friction of sliding. The bearings of the rolling wheel are also a source of difficulty and trouble. The complications, the first outlay, the trouble and expense of maintenance, the cost of renewals, all tend to relegate roller collectors (with some exceptions) into the category of interesting relics of the past.

So far we have been dealing with collectors gathering the current from plain surfaces. The subject becomes more involved with conductors of varying forms, and classification is difficult. It is interesting to note that though in some cases too little care has been bestowed on the collector, in other cases unnecessary complication has been introduced. An example of the latter will be found in Count Du Moncel's treatise on "Electricity as a Motive Power," published in 1883, wherein he describes the electric tramway installed by the Siemens firm during the preceding electrical exhibition, and run between the Palais de L'Industrie and the Place de la Concorde, Paris. It is thus described: "The conductors were formed of two copper tubes slit lengthways, and laid along a small piece of wood suspended horizontally to posts erected along the road. The movable rubber or jockey to connect the rubber with these tubes required very delicate adjustment. The contact was made by a metal cylinder placed in the tube, one end of which was connected to the other across the longitudinal slit. A roller wheel worked on the tube, and was pressed against it by springs, so that the contact took place both at the piece sliding in the tube and the wheel rolling on the outside. This was amply sufficient. Each of the two conductors had a runner of this description, which was attached to the tramcar by insulated wires. The current was brought by one and returned by the other." This collector, though interesting, was too cumbersome and complicated to be repeated. There is outcry enough now about depriving the sensitive citizens of the blue vault of heaven by stretching single wires along the street. What would they say to two tubes and a wooden plank? The complication was also unnecessary, for without tracing the various devices of expanding shuttles running within the slotted tube it may be stated that the simple arrangement answers quite well enough for practical purposes. Two shuttles were used so as to secure plenty of gathering surface, and they were connected together by hard brass strip. This enabled the collector to wriggle freely through points. A collector similar in operation to this was designed and tested for use upon the Metropolitan Railway, London, where the conductors are angle irons supported overhead by an insulated stirrup. The collector can in this instance at any time be lifted off the angle irons, which, as regards points and crossings, can be treated the same as the rails. The whole arrangement lends itself admirably to railway work, and is in all respects preferable to the mid-rail bar system.

In some of the earlier electric tram lines, constructed in America and elsewhere, two overhead wires were used, one for the lead and the other for the return conductors; and on these wires ran little trolleys or carriages, similar to the collectors used at Moorfield, Halifax, turned upside down, with the arms dependent, and with the wheels grooved instead of plain. Considerable difficulty was experienced in keeping the trolleys on the wires, partly because it was found impossible to fix and maintain the wires always in the same horizontal plane (especially on curves); one would sag more than the other, causing the trolley to tilt; and partly because the designs used did not provide sufficiently for the pull and side strain of the hauling cord. The most recent example of this class of collector is working in the tunnel now being constructed at Blackwall under the Thames, where special provision has been made to overcome the difficulties referred to. In all collectors that slide on or in the conductors, and that are pulled forward by a cord or other flexible connection, provision must be made against accident in the event of the trolley or shuttle becoming blocked. This has led to many releasing clips being designed. They in themselves form an interesting study, but it would occupy too much time to attempt anything like a description of them here.

Reference has already been made to the trolley collector used in the first experimental conduit, and its unfitness for regular work has also been explained. It will be difficult to give a sufficient reason for the design of the various collectors used in underground channels without a brief description of the channels themselves; and as this society has its home in Manchester, it may be well to commence with the one constructed in a field at Cornbrook in 1884, and compare it with the one now at Budapest. Their differences are more questions of proportions than anything else. The conductors in the Manchester channel are semi-circular, and in the Budapest angular. In both cases the collector must have some expanding arrangement in order to keep the rollers or shoes in contact with the half tubes or angle iron. The rollers were fluted spirally with the intent that they should twist when drawn forward, and so clear the half tubes of any dirt or dust that might accumulate. The Budapest arrangement differs only from designs made at the time when the Manchester line was constructed in that the shoes there were square, having to work in channel instead of angle iron. The Blackpool channel, as originally constructed, has been recently altered as follows: the two C-shaped conductors have been removed and replaced by one solid copper rod. This has necessitated a modification in the collector. It consists of three main parts, one centre-piece, and two clearing ploughs for enabling it to run in either direction. One of the elements of success is the employment of flexible collectors flexibly connected to the car, and automatically detachable therefrom. For this purpose the two ploughs are joined to the centre piece, either by tempered steel strips or hinged wrought-iron plates. The steel plates forming the ploughs are held by cast-iron cheeks placed at an angle, and extending downwards a little past the bottom of the steel troughs forming the surface of the channel. Their upper ends terminate in a hook or finger curved backwards. The hooks receive the "snap loop" of the hauling ropes, which are attached to the front and rear of the car. These snap links are strong enough for ordinary work, but should an absolute block occur they break and the collector is left behind, while the car by its momentum still travels forward, and the snap link of the trailing rope slips off the hook of the rear plough. If this were not so, the force required to break it would make the collector kick up and cause the contact making part of the centre-piece to short-circuit with the underside of the steel troughing. The centre-piece consists of a cast-iron clamp holding a plate of strong brass, which is thoroughly insulated and protected by hardened steel guards where it passes the channel slot. The bottom of the insulated plate is bared of insulating material, and has attached to it a flapper or wing, held outward by a spring, so as to maintain contact with the conductor rod. The current is taken from the collector by a short length of insulated wire, provided at either end with a clip, one end attached to a terminal under the car, the other to the upper end of the brass plate that passes through the iron clamps. In case of the collector breaking away these clips readily let go. Another form of collector that has been tried with good results is that in which the conductor rod is either suspended from the roof of the channel or rests upon insulators, and is picked up by a hook forming the gathering part of the passing collector.

As this paper treats only of things that have been or are in use, it would be somewhat premature to give any description of collectors designed and intended to be used in lines about to be constructed. Attempts to run electric tramcars in series by high-tension currents involve so much complication, difficulty, and disappointments that no useful

Digitized by Google

purpose would be served by describing any of the experimental collectors employed. A good deal has been written, and something has been done, in order to introduce closed underground channels; but it would be futile to attempt a description of the collectors without giving a full and particular account of the conduits themselves, and the various devices, electrical, mechanical, and otherwise, that they contain. They would form an interesting subject for a separate paper. Although not for a moment questioning the superiority of underground channels to overhead wires where the traffic is sufficient to justify the outlay, still the facility with which the overhead system can be constructed and worked, and its comparative small cost, renders it a thing to be desired by all who wish success to electric traction; for there are many lines that, if so equipped, could be made to pay, though the traffic would not be enough to secure a dividend on the larger outlay of an underground channel.

Reference has already been made to some of the difficulties pertaining to the use of trolleys or shuttles, or anything running on or in the overhead conductor. The trouble of fixing and removing, the constant risk of coming off, the strain put upon the conductor by the weight of the collector, and by the pull, necessitating the use of stays or poles very near together, all led to some better way being desired. One of the earlier examples of underneath contact is that employed by Dr. Hopkinson on the Bessbrook and Newry line, where a cross-bar supported on two upright poles, one on each side of the car roof, engages with the sag of drooping wires suspended over the track. This is simple, but not elegant. It requires two wires instead of one, it is difficult to adjust on undulating ground, and gives uncertain contact, the pressure on the cross-bar varying with the position the car occupies relative to the droop of the wire. A remedy for this was so self-evident that it is difficult to say who first thought of using only one wire stretched as taut as possible, and making contact by a movable cross-bar instead of a rigid one, for it must be admitted that those whose opportunities and position enable them to put a thing into practice are not always the first to conceive the idea. An advantage of this plan is the freedom for lateral movement. It facilitates the erection of the overhead wires on curves and at passing places. The chief weakness of the arrangement is the small point of contact between the round overhead wire and the round collector bar at right angles with it. Experiments have been tried with long rollers instead of the bar, and with curved plates free to rock, but none of them have proved really satisfactory. Of course the collector bars can be multiplied, but this adds to the unsightliness, and perhaps may account for the name "sky-scrapers" sometimes applied to them.

A similar but better arrangement is the "fishing rod," or, as it is more generally called, the "trolley bar," now largely used in America, where it originated, and to which the rapid advance in electric traction is largely due; and perhaps no one detail of equipment has had more thought and inventiveness bestowed upon it, for simple as the idea of a pole with a wheel at the top may seem, an instrument to fulfil all that is required is not easy to design. (1) It must of course be safe, strong, and light; (2) it must maintain good contact with the overhead wire, no matter how the height of the wire above the car may vary, and that contact pressure must, as far as possible, be uniform; (3) it must be capable of considerable lateral deflection, else curves and points could not be traversed; (4) it must be able to run in either direction safely; (5) it must be easily removable from the wire, and as easily replaced.

The cars that prevail in the States have no roof seats, which simplifies matters. Some admirable solutions of the problem are illustrated in figures accompanying Mr. Blackwell's paper read before the Institution of Electrical Engineers, therefore detailed description need not be given. A design about to be adopted in Bristol embodies a device, common to the American trolley bars, for equalising the contact pressure upon the overhead wire—viz., the triangular link, a most ingenious device requiring a little analysis. It is assumed that the pin sliding within the curved slot has a cam action, but inasmuch as this curved slot is struck from the centre of the pin, and that the plate from the pin may be regarded and acts as a simple link, it is very doubtful if the cam curve comes into action at all unless the trolley bar is swung right over, when the pin coming to the end or the slot could go no further, the triangular plate would become rigid, and the length of the leverage would increase.

Referring again to the necessity of securing approximately uniform pressure of the contact-making pulley against the underside of the overhead wire, a method is described in vol. xxiii. of the *Journal* of the Institution of Electrical Engineers. It consists of a pedestal somewhat like the upright of a jib crane, and free to swivel; near to the top of this pedestal the base of the trolley bar is hinged, near to the base is hinged a shorter bar, carrying at its end a link coupled to a joint on the "fishing-rod," thus forming a parallelogram. From the pedestal, at a point more or less close to the joint of the trolley bar, is attached a spring (or nest of springs), the other end being attached at the pivot point of bar and link, the springs thus passing diagonally across the parallelogram. The tendency of the spring is to close the parallelogram and keep the trolley bar at its highest position. It follows that if the trolley bar is depressed the parallelogram is expanded and the springs stretched, the varying leverage obtained by the parallelogram compensating for the increased tension of the springs, thus securing as nearly as possible a uniformity of pressure on the pulley end of the trolley bar through a wide range of movement.

It is impossible in one short paper to treat this subject exhaustively, and it is hoped that the omission of many other important and interesting devices may be credited to want of time and space, and not want of will.

SHORT-SERIES ARC LAMPS.

Messrs. Johnson and Phillips, 14, Union-court, E.C., have brought out a new short-series arc lamp (Brockie-Pell patent), two of which we illustrate herewith. That shown in Fig. 1 is for 7 to 30 amperes and for from 16 to 20 hours, while that illustrated in Fig. 2 is for 3 to 15 amperes and for 10 to 14 hours.

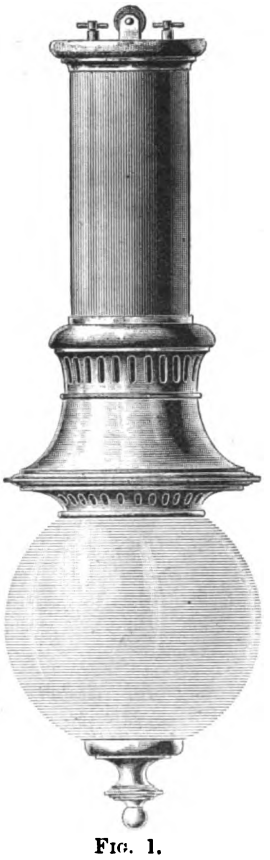

FIG. 1.

FIG. 2.

These lamps have been designed for use on low-potential circuits, particularly those supplied with currents from central stations. They work perfectly in single parallel, or two in series with 100 volts continuous current, four in series with 200 volts continuous current, or three in series (up to 15 amperes) with 100 volts alternating current.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

OUR TABLES.

We this week issue in tabular form information collected from authoritative sources concerning central stations, many of which are in operation, some are in preparation, and some only in contemplation. From time to time we have seen the information which the engineers to various local authorities have prepared for their committees and councils. Our columns contain, as far as we have been able to complete at present, the information which seems to be most in request by the local authorities. The progress of central stations has been rapid, and promises to be still more rapid. It has been our good fortune to contend from the very first that the generation and distribution of electrical energy should be in the hands of the local authorities, and not in the hands of companies. If men are not blind to the position of affairs, they will see from reading, say, Mrs. Green's "Town Life in the Fifteenth Century," that in the youth of municipalities the authorities were always jealous of outside interference. The town's affairs were carried out by the town's representatives. Then came civil wars and a decadence of interest in municipal work, and this lack of interest lasted till quite recent years. The energy and far-sightedness shown by several of the large provincial manufacturing towns in the early part of the later half of this century has borne good fruit, and all around new municipal interest is showing exuberant activity. The fiat has gone forth that municipalities must control sanitation, water supply, artificial light supply, and similar common matters. In all these directions the local authorities can do better and cheaper than companies, firms, or individuals. We were anathematised vilely and scurrilously in earlier days for standing out against the actions of prowling promoters of electric light companies. Many, however, who then doubted have changed their coats and agree with the correctness of our views. More and more municipalities are paying attention to lighting matters, and in many cases the mere fact that the gas is in the hands of a company makes it easier for the authorities to erect their own central stations. We do not assert that our tables are complete. It can be seen at a glance that they are not, but anyone who has had experience of attempting completeness in such things will readily admit that we have succeeded in getting together a mass of information that must prove of immense value to those authorities who are considering the matter. We claim to be saving the ratepayers in various towns a fairly large sum by means of this tabulation, for it will save their authorities the expense of preparing their own tables. Of course we shall correct, extend, and reissue periodically, and we trust our readers will not be afraid to send suggestions for making the information more perfect, or to fill up the blanks which are unavoidably left. The tables have been compiled by Mr. C. H. Biggs, jun., who has used as guides the local tabulations of Mr. Brown, borough engineer of West Hartlepool, and Mr. W. A. Davies, of Aston Manor. Great difficulty has been found in getting at the question of prime costs. It would be surprising to many of our readers to

Digitized by Google

see the great divergences that appear even in published and audited documents. The figures given to put before shareholders are found to differ from the figures put before the Board of Trade. No doubt, then, there will be more or less violent criticisms; but this we expect, and rather court. We prefer a good damning to no word at all, because it helps us to see where we fail and to correct our errors. We know these criticisms are impersonal—not aimed at the individual, but at the error. It might be suggested in one or two cases that it was possible to have avoided the errors by concert with the authorities. In every case, and many time and again, applications have been made to the authorities, and in the majority of items the figures have been authoritatively given or corrected. Procrastination is the bane of compilers of tables. Application is made to the authority, but the reply is not received till too late—hence some tears. We are glad to say, however, that in the case of these tables the delays have been unavoidable, and mostly due to the fact that the books connected with the various stations are balanced at different times. But enough of excuse. There is just one other question which the publication of these tables makes prominent. Here are already some two hundred central stations more or less, added to which must be as many more private installations, requiring electrical engineers-in-chief, as well as assistants. Does the Institution sufficiently recognise this fact? Its members and associates are being largely recruited from this source, and unless sufficient is made of these recruits we shall find them longing for an institution of their own. They are mostly ex-metropolitan members, and their claims on the Council must be recognised. When we criticise the Council list as issued, it is too late to make alterations; hence the necessity of calling attention thus early to the subject.

COST OF ARC LIGHTING.

An interesting historical point arises out of the remarks made by Mr. J. S. Raworth in the discussion on Mr. W. Langdon's paper at the Institution, which we were obliged to give in a very condensed form in our last issue. The question is that of the cost of the first arc lighting for railway purposes. Mr. Raworth said that as far back as 1879 he had the honour of fitting up for the London and North-Western Railway Company the station and goods yards of Holyhead with the best apparatus they could then command. They had five arc lamps fed by five small Siemens dynamos, and separate cables to each lamp. Although that was a pretty considerable undertaking at the time, it had worked satisfactorily up to the present, and he believed it was still working. The next step that company took was to get Mr. Raworth to light up one of the passenger platforms in the Victoria Station, Manchester, by means of alternate-current arc lamps. That platform was a long, narrow one, and it was lighted at the exceptionally low price at that time of 2½d. per lamp hour.

Now, Mr. Langdon tells us that the average cost per arc lamp hour on the Midland Company is 1·316d., the highest figure being at St. Pancras, where it was 1·61d., and the lowest ·93d., at Lawley-street, Birmingham, where seven-ampere lamps are used. This is a very marked decrease on the above, but not quite so much as might be expected after the improvements made in engines, dynamos, and lamps during the past fifteen years. We fancy that the arc lamps used in the old days at Manchester used about ten amperes, and as they were alternating-current they would not give the candle-power obtained by Mr. Langdon with his direct-current arcs.

Coming to other systems where a profit is supposed to be made on the light, we are informed by Mr. Leonard that the South-Eastern Railway pay fivepence per unit for the arc lighting as an inclusive charge. Assuming fifteen-ampere lamps, it would cost them about 3·8d. per arc lamp hour, but the candle-power would be quite double that of Mr. Langdon's lamps, and the Charing Cross and Strand Company have to get their profit out of this. The Corporation of London pay £26 per annum for a ten-ampere arc lamp lighted from sunset to sunrise, with extra charges for fogs. This charge works out to 1·43d. per lamp hour, or to 2·86d. per unit.

It is well known that these figures for street-lighting were purposely fixed at an unremunerative rate by the promoters of the City of London Electric Light Company in order to get the other concessions from the Corporation, and we have official information to the effect that in 1894 the actual cost of the public lighting by the City of London Company averaged 2·92d. per unit, showing a loss of ·14d. per unit all round. We consider that the cost of arc lighting is now rapidly approaching its minimum while the present fuels and machinery are used for the production of the electric energy, but the question of cost per actual candle-power might still be ventilated with advantage. We shall be glad to receive actual figures of measured candle-power, together with cost of production, from any of our readers.

SHIP-LIGHTING PLANT.

The combined engine and dynamo here illustrated is one of a pair recently constructed by Messrs. J. P. Hall and Co., Blackriding Ironworks, Oldham. The engine illustrated gives 18 i.h.p. when running at 250 revolutions per minute with a steam pressure of 80lb. The dynamo is of the usual direct-driving type made by this firm, and is compound wound, giving at the speed stated 150 amperes at 65 volts. The armature is of the drum-bar type, the driving power being transmitted to the winding by means of strong flat driving pegs let into the core, which is positively driven through keys let into the shaft.

The insulation largely consists of mica. The commutator contains 91 segments of hard-drawn copper, each being 1½in. deep. The current density in the armature conductors is below 1,000 amperes per square inch of section, and the rise in temperature does not exceed 70deg. F. after a 10 hours' run with full load.

The engine is fitted with the firm's new patent automatic expansion gear, shown in Figs. 2, 3, and 4. The governor disc is in two parts. The part F is keyed to the shaft, while the part G, Fig. 3, is an annulus connected by bolts and distance-pieces, V, to F, leaving an intermediate space, in which are contained the weights, I I, and the springs, M M, as shown in Fig. 2, which represents the disc, G, removed to display weights and springs. The weights are pivoted at H H, the upper one being provided with a tail piece so that the two weights can be connected together

Digitized by Google

by a flexible bar, K. Each weight has connected to it by a stud, L, and eyebolt, round which is coiled the helical spring, M. The eyebolt passes through a swivel lug, O,

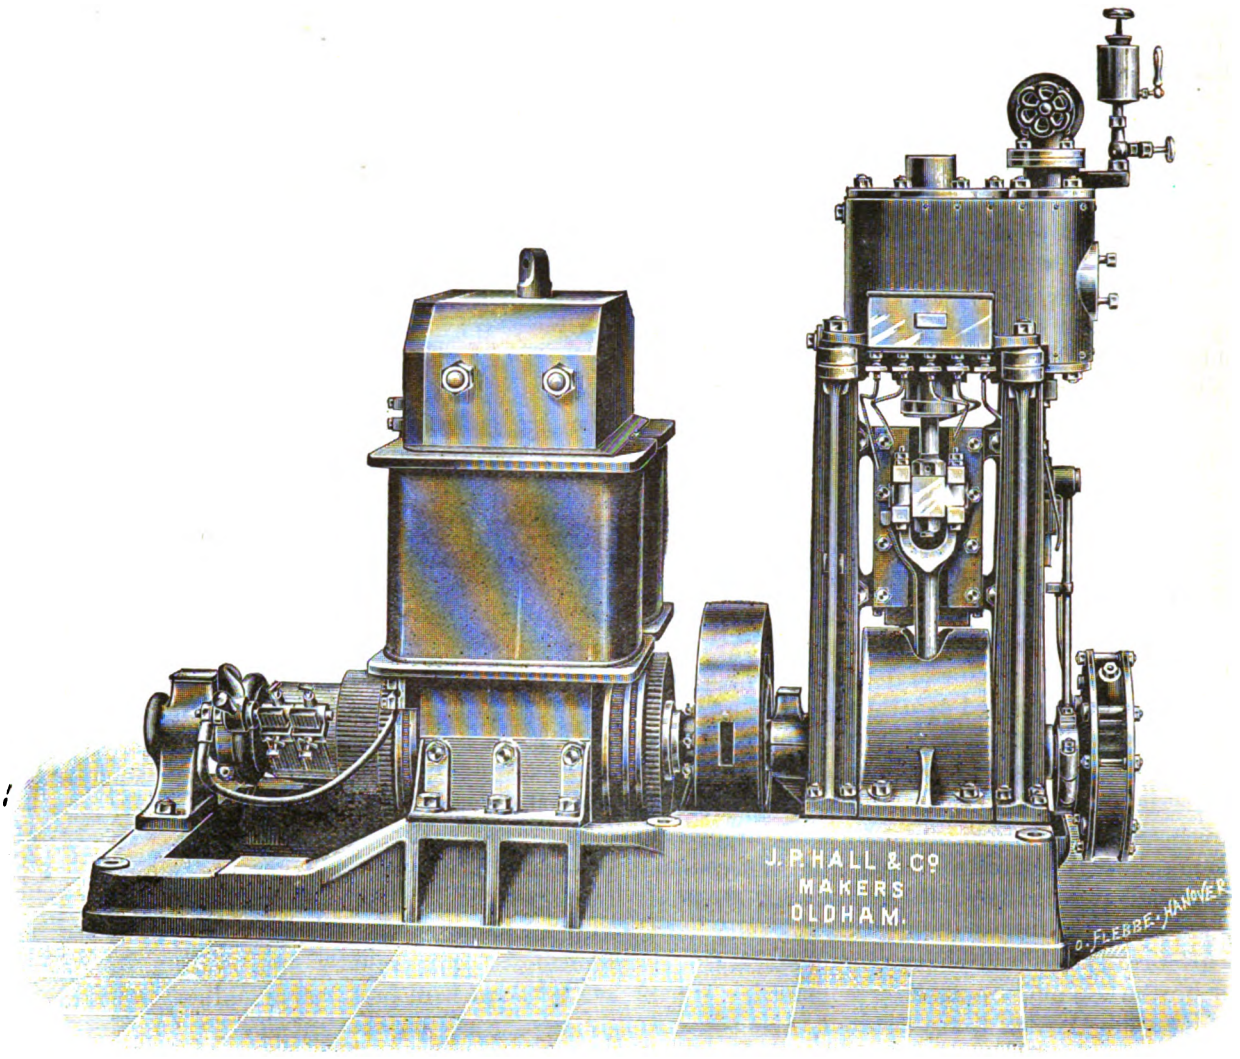

FIG. 1.—Messrs. J. P. Hall and Co.'s Combined Engine and Dynamo.

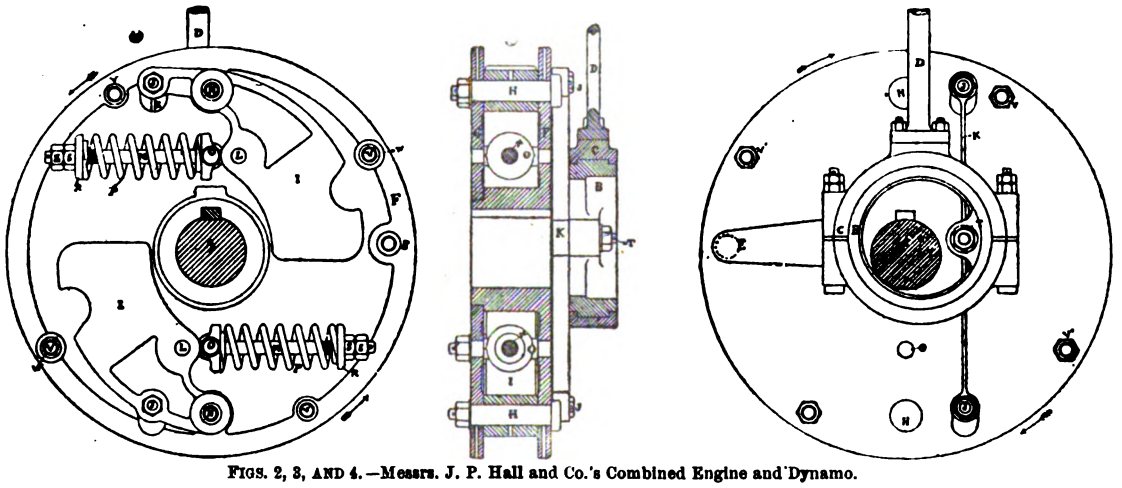
pivoted and free to revolve in the discs, F and G. The compression of the springs can be adjusted to balance the centrifugal action of the weights within a certain variation



FIGS. 2, 3, AND 4.—Messrs. J. P. Hall and Co.'s Combined Engine and Dynamo.

of speed by means of the lock nuts, S S. The flexible bar, which replaces the numerous connecting rods, pin, and joints hitherto used, is on the outside of the disc F, and takes on to the studs, J J, on the weights. These studs pass through slots in the disc, Fig. 4. At the centre of the bar is a forged eye that embraces a stud, T, on the eccentric, B. The eccentric, which has a large eye to enable it to move relatively to the shaft, has an extended ear pivoted to the disc at E. When the weights, I I, move in or out, owing to variations in the speed of the engine, the flexible bar, K, shifts the eccentric to vary the cut off. At the minimum travel of the valve the port is only opened by the amount of the lead, and at all other cut-offs the lead remains the same. The governor can be used for either right or left hand by reversing the position of the parts. It is exceedingly compact and powerful and works exceptionally easily, there being hardly any friction, and, as will be seen from the construction, will run for a long time without attention or developing slack joints.

Richmond (Surrey) Electric Light Company.—At a meeting of shareholders of this Company on Tuesday last the following directors were elected: Mr. F. W. Reynolds (director of the City of London Electric Lighting Company), chairman; Mr. W. C. Braithwaite (director of the County of London and Brush Provincial Electric Lighting Company); and Chevalier Soares. At a subsequent meeting of the directors, Mr. A. J. Lawson was appointed engineer and manager, and Mr. G. A. Luke, secretary, *pro tem.* Mr. Percy W. Northey remains resident engineer.

EFFECTIVE ELECTRIC LIGHTING.

BY W. PERREN MAYCOCK, M.I.E.E.

(Concluded from page 402.)

While on the subject of arc lighting, a few remarks on the ordinary use of arc lamps will not be out of place. The usual plan is to enclose the arc in a globe or lantern made of opal or ground glass. The former material absorbs from 50 to 60 per cent. of the light, while ground glass, according to its density, absorbs from 30 to 50 per cent. It will at once be seen how extremely wasteful is the usual method of dispersing or attempting to disperse the light rays. It is really only necessary to disperse the downward rays: the upward ones should be unobstructed, and then thrown down by a reflector. A lamp fulfilling these conditions, and made by Messrs. Joel and Co., of Wilson-street, Finsbury, is shown in Fig. 6. Here it will be observed that the bottom half only of the globe is opal, the top half being of clear glass, the opal hood serving to reflect the upward rays downwards. This form of lamp is a great deal superior to ordinary forms used in street illumination. In fact, the usual practice of outdoor arc lighting is very crude and unscientific. In spite of the globes, the lamps have a dazzling effect on the eyes if looked at for a few seconds, and sharp shadows are thrown, two things to be especially avoided in outdoor lighting. The lamps are put at a height of 18ft. or 20ft. in order that the light may be

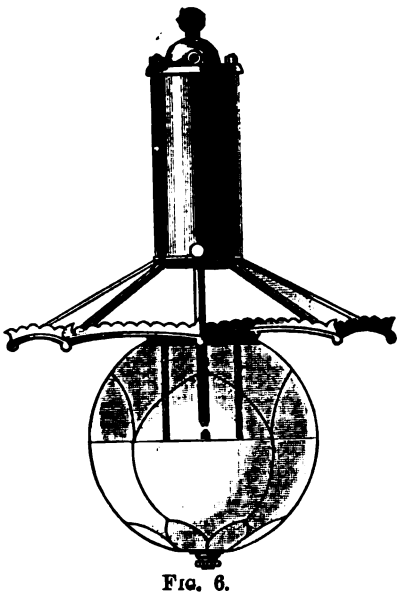

FIG. 6.

cast over a large area, and also that they shall not easily catch the eye. Much light is lost by placing the light so far above the ground, the height being also necessitated by the distance apart at which the lamps are placed. It is here suggested that more effective street illumination would be obtained by using lower candle-power lamps, placing them proportionally nearer together, at, say, the height of an ordinary gas lamp, using hoods of the pattern shown in Fig. 6, and making the bottom half of the globe semi-opaque, while of course retaining the interior reflecting surface; care being taken in the case of a direct-current system to have the positive or crater carbon at the bottom. The bottom half of the globe might be tinted a deep orange colour, which would give a very pleasing effect without glare.

Experiments have been made by Mr. A. P. Trotter in England, MM. André Blondel and Psaroudaki on the Continent, with clear glass globes and shades having prismatic corrugations on their surfaces, called variously dioptric or holoplane shades. These experiments have been entirely successful in obtaining a good diffusion of the light with little absorption, but difficulties of manufacture, added to the dirt-harbouring propensities of the corrugated surfaces, have done much to retard their adoption. However, the holoplane shades and globes of the two continental inventors, which differ in many respects from the devices of Mr. Trotter, are now being manufactured by Messrs. Englefred and Co., of Paris, and are being so well taken up on the Continent that it is very likely they will soon find their way into this country. These are made for both arc, incandescent, and other lights, and should find special favour for interior illumination, where they are not so liable to become dirty.

Let us now return to the consideration of incandescent lamp illumination, which has already been referred to at some length. Owing to the much less intensity and higher cost of the incandescent light as compared with the arc light, the lighting of interiors with reflected light from hidden lamps is necessarily rather an expensive matter. But where expense is no object, the effect obtained is all that could be desired, the light being warmer in tone than that from the electric arc. St. Peter's Church, Eaton-square, London, has been lighted mainly on this principle, the lamps being hidden as much as possible from the direct view of the congregation. In this instance 260 16-c.p. incandescent lamps replaced no less than 640 gas-jets. Freemasons' Hall, London, is lit by shaded incandescent lamps arranged around the frieze and on the ceiling.

It is only in rooms where the decoration of the ceiling and walls is in light colours that illumination by reflected light can be carried out, unless of course an unusual number of lamps are used, dull surfaces absorbing a considerable percentage of the light. In such cases the light should be thrown direct from the lamps through their shades. With a given method of shading the lights and a given size of room, the number of lamps required to give efficient illumination will depend upon the nature and colour of the surroundings; thus a dark wainscoted room would require more lamps than one with ordinary wall-paper and a whitewashed ceiling.

An excellent effect for any kind of room is given by the use of electric candle lamps, provided with suitable silk or paper shades. The flutings on the lamp bulb give a flame-

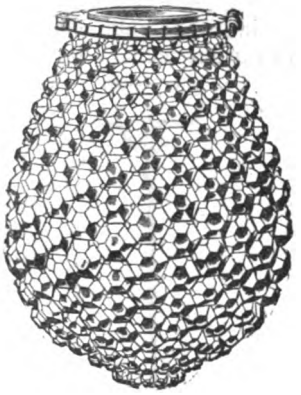

FIG. 7.

like appearance to the light when viewed from a distance, so that the dazzling effect is lessened; but still the shades should be arranged well over the lamps, so that the latter are seen as little as possible.

The majority of fittings, both electroliers and brackets, are arranged for the lamp to be hung downwards. This is a great mistake, as the shades offer little or no protection for the eyes. In some cases this difficulty is overcome by putting on a second shade under the lamp, so that an unnecessary amount of light is absorbed. Most of the usual forms of wall brackets would answer much better if they were put up upside down: the downward rays would then be more or less dispersed, while the upward ones would be quite unimpeded; care being taken to place the brackets at such a height that the top of the lamps were just visible when standing on tiptoe.

When downward hanging lamps are preferred, the lamps should either be shaded, or the bulb of the lamp should be frosted or treated with some composition which will prevent the filament itself from being seen. Of such shades there are numberless varieties, good, bad, and indifferent. Opal and ground-glass shades as a rule absorb too much of the light; while plain or coloured transparent shades will permit the filament to be seen, and will not disperse the light. Cut and etched glass shades best fulfil the required conditions. Fig. 7 illustrates the bead ray diffuser, the shade being built up of crystal or tinted cut-glass beads. If downward hanging lamps must be used, and the cost of shades cannot be

Digitized by Google

incurred, the globes of the lamps themselves should not be plain. Most makers supply lamps with frosted globes, and Messrs. Slade, Templeton, and Co., of 15, New Broad street, London, supply lamps with etched globes. Ordinary lamps can be treated with various compositions. The Luminous Enamel Syndicate, of 37, Cursitor-street,

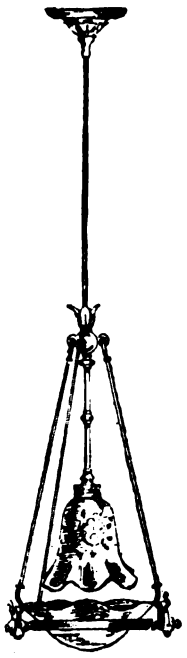

Fig. 8.

Chancery-lane, E.C., make a luminous enamel which, when applied to the lamps, entirely hides the filament, at the same time dispersing the light very effectively. This enamel is made in various colours, but the white is to be preferred for general purposes. Another composition,

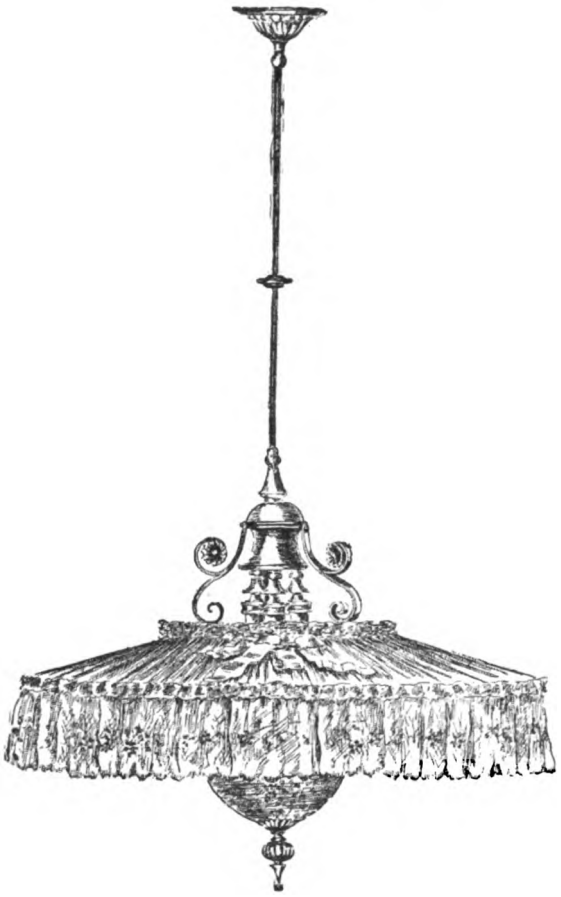

Fig. 9.

called "Snowflake," is made by Messrs. V. Fabris and Co., of 171, Drummond-street, Hampstead-road, London, N.W. Yet another is "Shaydolite," supplied by Messrs. Griffiths Bros. and Co., of Mack's-road, Bermondsey, S.E. This latter is of the nature of a varnish, and is made in various colours. "Shaydolite" being transparent, does not diffuse the light to any great extent, and does not hide the filament, but it is much used for theatrical and similar purposes where coloured lamps are a feature of the decorations. The advantage of these compositions is that they may be applied to the whole or part of the lamps. According to the position of the latter with regard to the eyes, it is well to treat only those portions through which the filament would otherwise be seen, leaving the rest untouched, thus impeding as little as possible of the light.

In selecting fittings, the guiding principle is thus to have only those in which the filament of the lamp is shaded from the eyes, but exposed on those parts not directly in view. Fig. 8, for example, shows a rational form of hall lamp. The lamp is entirely shaded from view, so that no direct rays can be seen. It may be said that the top shade is rather unnecessary, but then it must be remembered the light has to be screened from persons descending the stairs, as well as from those on the floor. Fig. 9 (which, as well as Fig. 8, has been lent by the General Electric Company) illustrates a table pendant lamp with cut-glass bowl, which serves to prevent the direct rays from the filament to some extent from striking the eyes. In fittings provided with bowls, like Figs. 8 and 9, a most pretty and artistic effect can be obtained by arranging natural flowers in the bowls, the flowers and leaves serving to obstruct the direct rays from the filament. Many forms of wall bracket are designed on this principle.

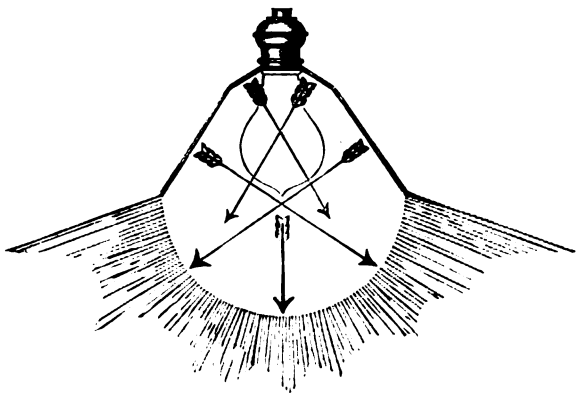

Fig. 10.

In Figs. 1, 2, and 3 are illustrated various forms of fittings which are specially adapted for shop-window or showroom lighting. A great deal might be said of this special branch of lighting, were space available. A walk down Oxford-street, for instance, at night-time will reveal the deplorable fact that in many cases the light has been unskilfully arranged, not always on the score of economy, as evidenced by the style of the fittings, but through sheer ignorance of what constitutes effective electric lighting. On the other hand, there are some installations that have been very well carried out, and which may be studied with advantage by those who contemplate undertaking similar work.

Enamelled iron shades or reflectors are a good deal used in some installations, and their efficiency depends much upon their shape. Fig. 10 gives a section of a shade made by Messrs. Verity and Sons, of King-street, Covent-garden, W.C. The figure shows by means of arrows the directions in which the rays from the lamp are reflected, and it will be seen that a good spreading out of the light is obtained.

In concluding this series of articles, it is hoped that the main points which must be attended to if artificial lighting is to be a success, have been sufficiently impressed upon the reader. Much more might have been written on this subject, but all would have tended to the same end, which may be summed up in two words—*reflection* and *diffusion*.

Referring to the holoplane glass globes mentioned above, since writing this article I hear that Mr. S. M. Scott has been appointed British representative and agent of M. Blondel's system. Mr. Scott's office and showrooms are at Cornwall Building, 35, Queen Victoria-street, E.C. Here the globes are to be seen fitted to all classes of lights—electric, oil, and gas.

MOUNTAIN-CLIMBING RAILWAYS.

BY ERNEST SCOTT.

The building of an ordinary railway, working by adhesion in mountainous districts, generally presents serious difficulties, and involves an expense in construction which is in excess of the return the line can make to its promoters. As a rule, the limiting grade is 1 in 40, and in order to keep within this limit the line must traverse a much greater distance than the direct route between the termini. This will probably include many engineering works, such as viaducts, embankments, walls, deep cuttings through solid rock, etc. For most mountain railways, therefore, some expedient, such as the rack and pinion, has to be used, and experience has shown that the rack may be employed without danger on gradients so steep as 1 in 2·5. While the construction per mile of track is much more costly than that of the ordinary railway, they are yet more economical from the fact that the distance between the termini is much reduced, an almost straight line being followed.

Switzerland, the happy hunting ground of the tourist, is peculiarly the home of the mountain railway, and by its means many of the peaks formerly inaccessible to the ordinary tourist can now be easily and quickly reached. The grand Alpine scenery alone would ensure its fame as a popular resort had it no other claims, but to specialists in various departments it presents an attractive field for the pursuit of their favourite study. In common with workers in other branches, the engineer meets with examples which have an especial interest for those of his profession, and which will arouse that close habit of observation which his work requires and creates. In Switzerland the engineer has achieved some of his cleverest feats. Such are the great water-power works at Schaffhausen and Fribourg, where wire ropes convey the hundreds of horse-power that are obtained from the swiftly flowing rivers all over the town, furnishing cheaply to manufacturers the means of driving their machines. They have impressed the dynamo into their service, and are ready to instal the electric motor in the most inaccessible of villages. Remarkable constructions, too, in many cases, are the bridges thrown across the rivers by the railway companies, while the difficulties overcome by the engineers of the many narrow-gauge and mountain railways have placed these lines among engineering wonders For the study of mountain railways nothing, indeed, could be better than a tour in Switzerland, for, while there are elsewhere isolated examples of similar construction, in the Alps a variety of systems can be examined at work on lines of the greatest difficulty. Judging from the number which have been built lately, and those that are projected, these railways seem to be an excellent investment, and that in spite of the enormous cost per mile in construction and the small mileage run in a season. Of course the wear and tear is comparatively low, whilst the rates are high. A few figures may be interesting.

According to official statistics, over 1,600,000 tourists visit Switzerland every year. The authorised passenger rate is 1s. 3d. per mile, yet in 1890 the Rigi line carried 101 000, the Pilatus 37,000, the Utliberg 68,000, Rothhorn 36,000, and the Generoso 20,000 passengers, the working season being limited from June to September, and the passengers in all cases being counted separately for ascent and descent. The working expenses of the above lines give an average of 47 per cent. of gross receipts, although on the Rigi and Pilatus the cost per train mile works out at nearly 10s. The net return on the capital invested is—Rigi 7 per cent., Pilatus 5 per cent., Utliberg 2 per cent., Rothhorn 5·5 per cent, and Generoso 2 per cent. The Swiss Government do not impose very stringent conditions on the promoters of these railways. The concessions are generally for a period of 80 or 90 years, with power to purchase at the end of 25 or 30 years. The authorised maximum speed on a gradient of 25 per cent. is four miles per hour, and on gradients of 40 per cent. and upwards one metre per second, or 2·3 miles per hour. These are, however, often exceeded, and could in most cases safely be doubled. Ten miles an hour is quite a common speed on gradients of 8 and 10 per cent. In case of bad weather the traffic regulations are such that if those responsible think necessary the trains may be delayed running. The Railway Department of the Government exercise the strictest supervision upon the material used on these railways, tensile strength tests, etc., being made at the Federal Testing Office at Zurich. The cables on cable railways and their connection with the cars are officially examined twice a year. They have to be renewed as soon as the tensile strength is less than four times the maximum working stress.

The difficulties that have to be guarded against in laying the line are: (1) Landslips or avalanches. The rails should be laid in sheltered situations, even if specially sharp curves are necessary. (2) Ordinary ballasting and sleepers are out of the question. Special precautions have to be taken to prevent creeping downhill, and yet at the same time ample allowance must be made for expansion and contraction for the differences in temperature, the differences of temperature in such situations as rack railways are generally placed in being very considerable. (3) The lack of adhesion, owing to the diminished action of gravity, has to be met. (4) Arrangements must be made to prevent the car being blown over by wind if surprised by one of the furious tempests and violent gusts of wind which are sometimes encountered at high altitudes. The avalanches constitute the principal difficulty in laying out Alpine railways, and their courses—indicated by scratchings on the ground—have to be carefully studied and avoided. On those lines worked by electricity, and which are much exposed to atmospheric discharges, efficient lightning arresters must be provided. In Switzerland they generally take the form of the ordinary toothed discharger, with impedance coil, condenser, and cut-outs.

Among the early devices for climbing steep grades was a plan for equipping the regular locomotive with a pair of horizontal friction rollers, arranged to press against a smooth centre rail and operated by a special set of cylinders. The Fell system is a development of this, and it has been adopted on the Wellington and Featherstone incline, New Zealand. The gauge is 3ft. 6in, and the gradient, averaging 1 in 15, is two and a half miles long. A train weighing 53 tons is drawn by an engine weighing 36 tons. The saving in capital cost in this case by the Fell railway, instead of an ordinary line, is estimated at £100,000. It has also been used on an extension of the Cantogallo railway in Brazil.

In the Fell system there is increased journal friction due to the pressure in keeping the gripping wheels in adhesion with the centre rail, whereas in the rack, friction, when there is any, is due to the imperfect adaptation of the pinion to the rack. The first is independent of the curvature of the road, while the other increases rapidly with it. There is, of course, some radius of curves at which the two systems would be equally favourable, an increase of the radius tending to give the superiority to the rack, while a decrease would tend to give it to the Fell system. Curves of as low as 140ft. radius can be traversed with facility working on the Fell system. It was customary to sand the centre rail, but the gripping wheels are now generally turned to the profile of the rail, and thus give ample adhesion In descending an incline, jets of water are played on the centre rail just in advance of the brake in order to cool it. The brake also lasts longer than when applied to a dry rail.

With the water-ballast system the cars are provided with suitable tanks. A load of water is taken on the car at the head of the incline, which causes it to descend with sufficient force to haul the other car up the gradient. On reaching the bottom the water is discharged from the first tank, while the one at the top is again filled. By alternately filling and discharging the tanks the cars are kept in operation. Where water can be got for nothing, or very cheaply, the water-ballast system is often used - *e g.*, the cliff railways at Scarborough and elsewhere—and also on several mountain railways, of which that from Lauterbrunnen to Grutsch is, perhaps, the most interesting. As the water ballast in the descending car is sufficient to start and haul the ascending car, the expense and maintenance of generating station machinery, and also electric motors on some of the lines, such as Monte Salève, is dispensed with. There are disadvantages, however: the ballast water weighs very heavy, and necessitates the frame and body of the car being made stronger to carry the tank so that the amount of the dead-load is out of proportion to the average passenger load. Thus on the Lauterbrunnen Cable Railway the weights are as follows: empty car, eight tons; water, seven tons; 40 passengers, three tons. These loads require correspondingly heavy cable winding drums, pulleys, etc. A ballast cable for the purpose of balancing the weight of the main cable, and thus reducing the requisite pull, is sometimes employed, as, for example, St. Beatenberg on Lake Thune and also at Bienne. This second cable reduces, but does not remove, the disadvantage of the ballast water. Mr. George Croydon Marks has gone very thoroughly into the water-ballast system, and at Lynmouth (Devonshire) and (Clifton) Bristol and elsewhere has applied a system of electric signalling, whereby the amount of water introduced into the top car-tank is regulated to suit the number of passengers who are to be brought up in the companion car, thus materially economising the cost of water.

The ladder rack was first used by Marsh on the Mount Washington line in the United States, and in Europe by Riggenbach on the well-known Rigi Railway. The Riggenbach ladder rack consists of two channel bars placed back-to-back, and 5in. apart. The bars are bolted together with trapezoidal rungs of steel, which serve as teeth, and are so disposed as to engage three teeth of the pinion wheel. The whole is bolted to cross sleepers, and the ends of each length are further secured to the sleepers by angle irons. Nearly all the more recent lines have been laid down on the Abt system, a description of which follows. The line at Barmen is, however, an exception; here the ladder rack had to be used because part of the line is laid in the public road. The Wengern Alp is also another exception. Although the ladder has come into quite extended use, it has serious inherent defects which incapacitate it for high speeds. The prime requisite for a smooth and quiet motion is uniformity of pitch, and it is almost impossible to manufacture a long ladder rack without introducing elements of error. Again, the diameter of the pinion to secure proper contact with the teeth is so large that the power from the steam cylinder has to be transmitted to it by multiple gearing. The tendency of modern practice has been to abandon the ladder and adopt a rack which is essentially built up of two or more individual racks placed side-by-side. The idea or principle is the same as that which led up to skew bevel, and afterwards to the well-known double helical gear. As applied to railway work, it is known as the Abt system, and is employed to a considerable extent.

The Abt double rack generally consists of two steel bars, 1¼in. thick, and placed 1½in. apart in such a way that the tooth in one plate is opposite the space in the other plate, "staggered" with respect to one another. The rack is attached to alternate sleepers by T-shaped chairs, to the web of which they are fastened by transverse bolts, the chair itself being fastened to the centre of the sleeper by stout bolts. This kind of rack lends itself to economy of material very readily, because on gradients of less than 10 per cent. only one rack bar is used, with, of course, only one pinion working in it. Above 10 and up to 25 per cent. both rack bars and the two pinions are in operation; in the former the pinions have a double and in the latter a fourfold grip. The

Digitized by Google

motion is more continuous and obviates the slight hammering of the pinion teeth incidental to the ladder rack. This is of great advantage where electric motors are used as the propelling power. Loose connections at the commutator joints are not caused by the unevenness of the roadways so much as by the load coming off and on as each tooth of the pinion engages and disengages with the line rack. As there are over 300 miles of the Abt track already constructed in different parts of the world, we may take it that it has effectually vindicated the advantages it claims as compared with other forms of rack. As a general rule these rack railways are isolated, having no immediate or material connection with adjacent systems. There is, however, on the Continent a growing number of continuous lines traversing mountainous districts. They are operated by locomotives having a double set of cylinders. One set actuates the ordinary wheel adhesion system in the usual way on the level or low grades, and the other set is brought into use additionally for working the rack pinions on the steep grades. This is known as the Abt rack and adhesion system, and it is to be hoped that the extensions soon to be made in this country in the direction of light railways and tramways will afford instances where lines of this character may find advantageous employment. On lines of this combined system it is, of course, important that the rack rail be properly entered by the pinion without slackening the speed of the train. This is accomplished by laying down a special entering rack rail. It is about 10ft. long, and is hinged to the rack at one end; its free end rests upon strong spiral springs, which allow it to give slightly. The teeth towards the free end gradually diminish in height, giving it a wedge-shaped appearance. As the locomotive passes over the entering rail the pinion is turned by friction, and within a few feet a true interlocking of the teeth is secured, when steam is admitted to the extra pair of cylinders for climbing the gradients. The rack wheels are almost always vertical—that is, their plane of rotation is parallel to the road wheels. An exception is the very heavy gradient on the Mount Pilatus Railway. There the danger of the pinion rising out of gear when full work is on, owing to the diminished action of gravity, is overcome by having two horizontal pinions working into racks which are back-to-back. This is Colonel Locker's invention. The difficulty can be met with the ordinary Abt rack, however, by fixing to the bottom of the car two vertical anchor bars, which travel between the rack bars, and whose flanges press on the bottom surface of the rack bars in the event of the car rising. This has been done on the Burgenstock line, which has a gradient of 58 per cent.

The rack on the St. Ellero-Saltino Railway is the invention of Count Joseph Telferer. It is built up of bars of Siemens-Martin steel angle bars, thickened up at the teeth with plates. This rack is cheaper than the others. It costs about 14s. per lineal yard.

Another type, known as the Agudio system, is in operation near Torrino, Italy. In this system a small wire rope driven from the terminal station in the same manner as for cable lines, is led over two sheaves attached to the side of the motor car, and by means of reduction gear transmits power to two horizontal cogwheels, which embrace a central cog or rack rail, and propels the motor with sufficient power to push a train of several cars on a gradient of 38 per cent. The cog-rail is of peculiar construction, being a steel ribbon bent zig-zag in such a way as to present teeth on each side. This is fastened by means of channel bars and bolts to a central beam. The motor is in a measure independent of the cable, and by means of friction clutches the train can be stopped or run backwards.

The first rack railroad that was ever built is without a doubt the one put down by Blenkinsop in 1811 between the coal staith at Hunslet, Leeds, and the Middleton Colliery, Mr. Blenkinsop being manager and part proprietor of these collieries. As there was a steep gradient at the Middleton end of the line it was thought (and rightly too) that with the light weight of engine which was being built that sufficient adhesion could not be obtained between smooth wheels and rails. A cast-iron rack was therefore laid down alongside the ordinary rail. As Blenkinsop knew little about engine-building, he gave the order for the engine to Matthew Murray, of the Round Foundry, Water-lane. Murray is one of the many engineers of whom Leeds has good reason to be proud. He was one of the first to take up stationary engine building in this country, and as an example of the work he did may be mentioned the fact that an old beam engine which he built is still used for driving the works at the Round Foundry, a counterpart of this same engine being also the first to be set to work in Russia. Murray's engine ran its first trip in August, 1812, just 8½ years after "the father of the locomotive," Trevithick, had run his first and only engine on the Penydarran cast-iron tramway, near Merthyr Tydfil, and two years before George Stephenson's first engine "Blucher," was set to work on the Killingworth railway. Murray's engine had two cylinders, and the energy was communicated by connecting rods and crank to a large cogwheel, which worked in the rack fastened to one of the rails, the four ordinary wheels of the engine being simply supporting wheels. Locomotives of this design conveyed coal from Middleton to Hunslet for several years.

The next rack railway was built by Sylvester Marsh up Mount Washington, New Hampshire, U.S.A. It was opened in 1869, and was 3·29 miles long, with a maximum grade of 37 per cent., the minimum being 10 per cent. The rack is in the form of a narrow ladder, having angle iron sides and rings of round bar iron 1½in. in diameter placed 4in. apart. The rack and track rails are spiked to wooden sleepers, which are securely anchored by straps and bolts to the solid rock formation.

The summit of the Rigi can be reached from Vitznau, on the Lake of Lucerne, or from Aarth Goldau, on Lake Zug, the first-named being the oldest and steepest route as well as the best paying. The track has a standard gauge of 4ft. 8½in., and is carried on sleepers that rest on solid rock which has been cut out to a depth of 1ft. to receive them. At Freibergen, a station midway on the line, there is a passing place of peculiar construction; it consists of a sector of sufficient length to contain the locomotive and car. When the train has passed on to the sector, which is hinged by an iron pivot and provided with wheels, it is turned round until the line is clear and the opposing engine is allowed to pass. The locomotive weighs 12½ tons, and has a vertical boiler arranged to be perpendicular on an incline of 1 in 4. There are four flanged supporting wheels, and on the rear and front axles are mounted the cast-steel rack pinions. Passengers make the ascent in two storeyed cars, designed to carry 46 in the lower and 36 in the upper compartment. Although the Rigi is 1,000ft. higher than Ben Nevis, the hotels on its summit are crowded during the season with tourists who have come to see the sunrise or sunset, whose attractions have been so often described.

The railway to the summit of Mount Pilatus (so called because by tradition it was the mountain from which Pontius Pilate finally ended his life by throwing himself into the Lake of Lucerne) was first surveyed in 1885. The grades of this line being very severe, the builders had to adopt a new type of road invented by Colonel Locker. The rails are placed on iron ties, the latter being firmly fastened to granite blocks on a substructure of solid masonry. The car wheels are without flanges so as to reduce friction, the train being kept on the track by the centre rack, which forms a sufficient guide. There are two racks placed back-to-back, or teeth on either side, into which four horizontal toothed wheels gear, two at the forward end and two at the rear end of the car. With the axes of the driving wheels being at right angles to the plane of the line, any tendency to rise out of gear is mutually resisted, and thus perfect security is obtained as far as regards danger. The rack is in lengths of 10ft., the teeth being milled out of solid steel bars. The engine is by the Locomotivefabrik Winterthur, fitted with self-adjusting cylindrical valves and Brown's patent valve gear. In order to save weight and give greater security, engine and car are combined. The whole vehicle is carried by two axles, upon which it is supported at three points—namely, at the centre of the leading and at the ends of the following axle. The horizontal multitubular boiler is placed transversely to the track so as to keep the water on a level. There are specially arranged clips, which are fitted over the rail heads in order to prevent the car from being blown over by the wind if surprised by one of the furious tempests which are sometimes encountered at these high altitudes. The clips are made long enough to prevent jamming, and the connection with the frame of the carriage is such that a small amount of vertical play is allowed in the direction of the length. The cars are protected by two hand-brakes, one ordinary air-brake, and an automatic brake, which fits into the gear teeth and is operated by a wedge when the speed exceed 3½ miles per hour, so as to eliminate any chances of danger through inattention of brakesman or drive. The principle of using the cylinders also as an air-brake was first applied by Riggenbach on the Rigi line; it has had many applications since, notably the Rothhorn engines. In coming down, the motion of the wheels being of course reversed, air is sucked in at each stroke of the piston and pressed into the steam-pipe. If it is not let off by means of the special stop-valve in the driver's cab the pressure rises and gradually arrests the motion of the pistons. The driver regulates the air stop-valve just as he does the steam-regulator in the ascent: the more the valve is opened the greater the speed, and *vice versâ*. It is interesting to note that electric brakes are fitted on the Mount Salève, which act in just the same way, the electric motors working as dynamos on the descent.

(To be continued.)

INCRUSTATIONS ON INSULATORS.

The following is the report of the committee of members of the Royal Society and the Institution of Electrical Engineers appointed to confer with the electrical adviser to the Board of Trade with regard to the circumstances connected with the formation in large quantity of an alkaline deposit on the mains of the St. Pancras electric light supply, and the presence in this deposit in some cases of the alkaline metals in an unoxidised condition:

The committee have held three meetings, and a *précis* of the proceedings at these meetings is attached to this report.

After taking evidence as to the present condition of the mains of the St. Pancras electric lighting system, and after receiving from Prof. Thorpe reports of analyses, made under his direction, of the chemical composition of the incrustation found on the insulators of these mains, and of the salts contained in the bearers of these insulators, the mortar and concrete of the conduits, and the adjacent soil, the committee are of opinion that the explosions which have occurred were caused by the firing of an explosive mixture of coal gas and air by sparks caused by means of the above-mentioned incrustation.

Digitized by Google

It has been proved that sparks may be caused either by the incrustation itself acting as an imperfect electrical conductor, or by moisture coming into contact with metallic sodium or potassium, both of which metals have been found to exist within the incrustation.

These metals have been produced by the electrolytic decomposition of alkaline salts chiefly derived from the soil, and conveyed by moisture along the fibres of the wooden bearers towards the negative conductor.

To avoid a repetition of these accidents, the bearers of the insulators at present in use should be replaced by other devices through which moisture is prevented from travelling, and it is recommended that the pattern of insulator in use should be changed, and a pattern adopted in which a longer insulating surface is interposed between the conductors and the bearer.

The committee is also of opinion that it is desirable that means should be provided by which the conduits can be inspected throughout their length, so far as is necessary to detect incrustations on the insulators.

The committee have not thought it within their province to investigate the causes of the presence of coal gas within the electric lighting conduits, but it is obvious that this is the primary source of danger.

(The report is signed by Major P. Cardew, Lord Rayleigh, Prof. T. E. Thorpe, Prof. William Crookes, Mr. R. E. Crompton, Mr. Alexander Siemens, and Prof. Alexander B. W. Kennedy.)

The following is the *précis* of the proceedings of the committee :

Meetings of the committee have been held on March 4, 8, and 22.

At the first meeting, Mr. Baron, chief engineer of St. Pancras Electric Light Works, gave detailed evidence as to the deposit or incrustation on the insulators on the St. Pancras mains, from which it appears that it was first noticed about 18 months ago, and found to be alkaline ; that 60 to 70 per cent. of the whole number of insulators which can be examined—*i. e.*, those in or near the street boxes—are affected by it, and that in some cases when scraped off it forms again within 24 hours ; that the insulators which are supported on wood bearers at the various street boxes are those generally affected, and only in two or three cases has any incrustation been found in the intermediate insulators within the culverts, which are supported on iron brackets. These wood bearers have become thoroughly saturated with saline moisture. They are supported at each end by being let into the brick sides of the culvert, and in some cases the end fibres of the wood may be in contact with the soil. Mr. Baron has seen the deposit flame with a yellow sodium flame in several instances when water was dropped on to it, or when it was dropped upon wet ground. He has also seen sparking from the negative main over the insulator to the wood bearer, and has produced the same by experiment with a solution of the material deposited. The insulator in this test was moistened on the surface with clean water, and the wood bearer was standing in the solution. The sparks occurred in about five minutes. The glaze on the insulator has been attacked in some cases. He does not think that the process of salting the streets in order to melt snow has any connection with the formation of the deposit.

Mr. Miller, of the Kensington and Knightsbridge Electric Lighting Company, also gave evidence as to leakage from the negative main always attracting moisture, and stated that a negatively charged cable belonging to his company laid in the subway at Kensington Court had a small fault of insulation, which apparently gave rise to a moist efflorescence on the adjacent brickwork, which if brushed with the hand emitted a sort of phosphorescent light in the dark. His company had experienced no trouble from incrustation on the insulators, but very high-quality insulators of hardened glass or porcelain and of the double-shed pattern were used. In their system every insulator used can be easily examined.

On March 6 Lord Rayleigh, Prof. Crookes, and Prof. Thorpe visited the St. Pancras mains. At a street box near the Chester Gate, Regent's Park, a piece of incrustation in a moderately hard and friable condition about the size of a hazel nut was taken from the negative main. This was placed on the cover of the street box, and some water put on it, when it broke into flame. There appeared to be several nodules of metal, one about the size of a pea. This metal was solid. Some flashes of sodium flame were also seen along the wood bearer as if the metal had been deposited there. The wood was saturated with moisture, especially under the negative. This wood bearer was subsequently sent to Prof. Thorpe for examination. At the places corresponding to the position of the negative mains the wood was much blackened and carbonised and very wet. On cutting it into six pieces it was found that the wood was saturated with alkaline salts, which were strongly caustic near the negative main, and chiefly carbonates of potash and soda at the ends. The soil, mortar, and concrete at this point have also been tested by Prof. Thorpe, and his analysis appears below.

At the second meeting of the committee Mr. Crompton produced three specimens of deposits taken from the insulators of the Southampton electric light mains. These have also been analysed by Prof. Thorpe (see below). Prof. Thorpe produced an analysis (see below) of three samples of the deposit obtained from the St. Pancras mains. Considerable discussion took place as to the exact process by which the incrustation and the free metal were produced, and it was finally decided to have another meeting before reporting.

At the third meeting, on March 22, further specimens from the St. Pancras mains were examined and Prof. Thorpe's analyses were considered. A glass insulator from the Southampton mains showing a considerable amount of deposit, was also submitted. The report was then discussed and adopted.

ANALYSIS OF DEPOSITS OBTAINED FROM ELECTRICAL MAINS.

Sample from St. Pancras Mains, received March 2.—The substance had the composition :

Caustic soda	7·69 per cent.
Caustic potash	4·88 ,,
Sodium carbonate	34·40 ,,
Potassium carbonate	52·77 ,,
	99·74 ,,

(+traces of silica, alumina, and lime.)

Three Samples from Southampton, received March 9, 1895.—All are practically pure sodium carbonate, with a very small admixture of potassium carbonate. The sample taken from the earthenware insulator is amorphous, and contains appreciable traces of calcium carbonate ; the other two (from glass insulator and distributor) are crystalline, and free from all except adherent impurities. None of the samples contain free alkali.

Soil, Mortar, and Concrete from St. Pancras.—The aqueous extract obtained from each of these by slow percolation had an alkaline reaction (alkalinity = from ·12 to ·13 gramme NaHO per 250 cubic centimetres of extract), and contained in each case compounds of sodium and potassium, the latter being present in moderately large proportion. T. E. THORPE.

March 21, 1895.

THE SELECT COMMITTEE ON TELEPHONY.

The Select Committee of the House of Commons appointed to enquire into the working of the telephone system resumed the hearing of evidence on Friday last.

Mr. Harcourt E. Clare, deputy town clerk of Liverpool and member of the council of the Association of Municipal Corporations, was called. He said that, together with the town clerk of Leeds, he had been asked to give evidence on behalf of the association. Their view was that the telephonic system was now an absolute commercial necessity, as well as a great convenience for private and domestic purposes. It was most important that the communication between the large centres of population should be made as cheap and as easy as possible. This was much more important than the development of the telephone system within any given area. The great proportion of the Stock Exchange business between Liverpool, Manchester, and London was done by telephone. The whole telephone system must be considered as a national undertaking, and ought not to be treated in each centre as a local matter. The view of the association was that the Government ought to take over the whole system, as the telephones had been declared to be a part of the Postmaster-General's monopoly. But if the Post Office and the Treasury thought that this was not advisable, of course they must look for some other solution of the question. The immediate effect of the Government taking over all the trunk lines, and those only, would be to cause delay in the intercommunication of local centres on account of the increased number of connections. But this undoubtedly could be remedied by increasing the number of trunk lines, and if the Government were prepared to do that to a greater extent than the company, then the public would benefit from the Government's acquisition of the trunk lines. But from the terms of the agreement between the Postmaster-General and the company he could not see how the public were to get any reduction of charges or increase of facilities unless there were a great extension of the trunk lines. If the Government did not take over the whole telephone system there was only one course to be followed, and that was to place all local exchanges under the control of one body, such as the National Telephone Company. It would be a national evil if any local area was allowed to separate itself from the rest of the country. He expressed the opinion of the entire Association of Municipal Corporations when he said that the municipalisation of local exchanges was impracticable and wrong in principle. Competition in telephones within any area could only result in increased expenditure He was strongly of opinion that the rates ought not to be pledged for the establishment of a trading concern, such as the telephone, which might prove to be a loss. The telephone was chiefly for the convenience of capitalists and well-to-do people—it was not for the benefit of the people at large, like gas and water ; and therefore he thought that the municipalisation of the telephones would be a very great mistake. The association which he represented practically included all the municipal corporations of the country, with the exception of the London Corporation. The telephone service would never be as cheap as it ought to be so long as the telephone companies had to work under a license terminating in 16 years, and under conditions which did not authorise them to maintain their undertakings. Their systems were constructed and maintained merely on sufferance. They had really no right to exist. Consequently they had to pay heavy charges for way-leave and other charges, somewhat in the nature

Digitized by Google

of blackmail, to persons who had them "in a tight place." The companies ought to have, if the Government did not take over the whole system, the power to maintain their undertakings in a proper way and to utilise the streets for laying their lines, subject to the control of the corporations. He thought that a parliamentary committee should be appointed to enquire, not only into what powers should be given to the telephone companies, but also into what restrictions and conditions should be imposed as a return for the concession of the powers.

The **Chairman**: Such an enquiry comes strictly within the terms of reference to this committee.

Witness, continuing, said that as to the powers to be conferred possibly the powers possessed by the Postmaster-General under the Telegraph Acts might be all that were necessary, subject to some slight modification. As to the utilisation of the streets, the corporation of each town ought to be left absolute discretion as to whether the wires were to be laid underground or overhead; if underground, the corporation should have the right to lay the wires themselves for the company, charging the company with the cost. At present all the corporations had agreed to withhold their consent, under the Act of 1892, to the use of the streets for the telephones until an Act of Parliament was passed enabling them to impose the necessary restrictions on the telephone companies. Having fixed the powers which it was desirable to confer on the companies, the next point was the restrictions to be imposed. He suggested that the first should be a fair maximum dividend fixed on the capital of the company, having regard to the amount of it represented by their works. It might appear that a large portion of the capital was not such as the public ought to be called to pay a dividend upon. Next, maximum charges should be fixed. In the agreement with the Postmaster-General the whole country was divided into exchange areas. These might be classified and maximum charges fixed for each. There should be accompanying provisions to prevent the companies from unfairly favouring one exchange area at the expense of another, or one subscriber over another, where the circumstances were exactly the same. Further, the telephone subscribers being mostly well-to-do people, it might be well to consider whether the use of the telephones could not be extended by the establishment of call-offices which could be used for a small fee by those who could not afford to be on the exchanges.

The **Chairman**: What considerations do you propose to offer for the imposition of these restrictions on companies which have at present an unrestricted license?—**Witness**: You would give the companies extended powers of maintaining their undertakings; and the term of the licenses would be abolished, placing the companies in the same position as the gas and water companies, subject to provisions safeguarding the public from an oppressive monopoly. The Government should retain the power to acquire the whole telephone system upon fair terms and after reasonable notice, to be given at certain dates fixed by Act of Parliament.

The **Chairman**: The committee of 1892 reported strongly against the extension of the existing licenses.—**Witness**: The corporations did not appear before that committee; and it stands to reason that when the company is working under a license which practically ends their undertaking in 16 years they cannot develop their system or work it as cheaply as if they had a permanent existence. They must put by out of their revenue a large reserve fund, and this comes out of the subscribers' pockets. What the corporations want is that the Postmaster-General or some company should supply a telephone service of the best and cheapest kind, and we do not want to pay, as we do now, high prices for an unworkable system. As a matter of policy, witness said, he thought it was a great mistake on the part of the Postmaster-General ever to have farmed out any part of his monopoly. The purchase of the telegraphs was pressed on the Government in order to secure uniformity, and he would apply the same principle to the telephone system. Competition between the company and a corporation might, no doubt, lead to serious loss, not only to the corporation but also to the company, and any loss by the company in one area would have to be made up in another. If the Corporation of Glasgow wanted a system of their own, he did not see how Liverpool could interfere. He had never heard of any English corporation asking for or desiring a license.

Mr. John Harrison, town clerk of Leeds, said that speaking generally, he agreed with what Mr. Clare had said with regard to the municipalisation of telephones, though he was not authorised to speak on behalf of his Corporation. The best course of all would be, in his opinion, for the Government to take over the telephones. Failing that, one strong company should work them, with the exception of the trunk wires, under severe obligations and conditions. He would scarcely agree that the corporations were not in favour of competition, but if competition were allowed such persons connected with corporations as he had spoken to would be in favour of allowing corporations to join in the competition if they desired to do so.

Mr. W. H. Dickinson, deputy-chairman of the London County Council, said that the opinion of the committee of the Council which had been dealing with this question was that the operation of the agreement would very greatly strengthen the position of the telephone company, and would practically give them a monopoly for the whole kingdom.

The **Chairman** pointed out that no evidence against the policy of the agreement could be received. The only question that could be dealt with was the sufficiency of the telephone service throughout the country.

Mr. Benn urged that this was a very important matter, and, a discussion arising, the room was ordered to be cleared.

On the reopening of the doors it was announced that the committee had adjourned until April 26.—*The Times.*

LEGAL INTELLIGENCE.

SOUTH STAFFORDSHIRE TRAMWAYS COMPANY.

Judgment was delivered on Friday in this case, which was argued last month before Lord Halsbury and Lords Justices Lindley and Smith. The appeal was from the decision of Mr. Justice Kekewich, who held that the plaintiff and the mortgage debenture-holders whom he represented were not entitled to an order for sale or to the appointment of a manager, although the Company was in default. The Company was formed in 1883 and reconstructed in 1889, and its debenture debt amounted to £50,000. Mr. Justice Kekewich substantially held that a tram company must be treated as a railway company, which is by statute exempt from the operation, in case of default, of the provisions of the Companies' Act, 1862. Their Lordships confirmed that view, and dismissed the appeal with costs.

THE CASSEL GOLD EXTRACTING CASE.

In the Court of Appeal, on Tuesday, Lord Justice Smith delivered the considered judgment of the Court in the matter of the appeal from the judgment of Mr. Justice Romer, in the action of the Cassel Gold Extracting Company *v.* the Cyanide Gold Recovery Syndicate, Limited. The action was brought for the infringement of patent rights for a process for treating gold in crushed ore, and for recovering gold from tailings by the process known as the cyanide process. The defendants did not at the trial deny infringement if the patent was good; but they attacked the plaintiffs' patent, and Mr. Justice Romer held that it had been anticipated, and was consequently invalid. Against that decision the plaintiff company appealed, and the appeal was argued during several days in February last.

Lord Justice Smith, after describing the nature of the invention, by means of which in South Africa in 1893 no less than 500,000oz. of gold had been recovered, said the defendants did not deny the utility of the invention, nor did they deny that, if the patent was valid, they were infringers, but they denied the validity of the patent—first, on the ground that the process was old and well known to chemists and others at the date of the patent; and, secondly, that the patent was bad because the specification was too wide. It was proved that for many years prior to the date of the patent it was common knowledge that cyanide of potassium would extract gold in a finely divided condition. There was no doubt about that. This fact was contained in a paper read by Prof. Faraday in 1840, and there were patents taken out by Ray and Simpson, who obtained gold in solution, and then extracted it by means of electricity. After minutely describing these patented processes, his Lordship said the defendants failed to prove that they were able to treat gold in crushed ore and in tailings so as to give any good commercial results. As to the state of knowledge prior to the date of the plaintiffs' patent, the evidence showed that it was not known to Prof. Dewar, Prof. Crookes, Sir Henry Roscoe, Lord Kelvin, and other experts that a diluted cyanide of potassium had a selective action, and would treat gold before touching the baser metals, whilst a strong solution treated the gold and silver and baser metals at one and the same time. There was novelty and utility in the plaintiffs' invention, and in this respect their lordships differed from Mr. Justice Romer. But on the specifications—the provisional and final—their Lordships came to the conclusion that there was disconformity between them, and that the two specifications could not be read as having the same meaning. The provisional was a claim for all solutions of cyanide of potassium, and the final was for a dilute solution. Sir Richard Webster urged that they were one and the same thing, but their Lordships held that the first claim was for any solution of cyanide independent of its strength, and this claim being too wide there must be a judgment for the defendants.

The appeal of the plaintiff company was therefore dismissed with costs.

A QUESTION OF SHARE TRANSFERS.

In the matter of the New Zealand Electrical Syndicate, Limited, **Mr. Leigh Clare** on Tuesday asked Mr. Justice Kekewich, on behalf of Mr. C. F. Kemp, to direct that certain shares be registered in the books of the company, so as to vest those shares in him as the voluntary liquidator of the Gulcher Company. The shares, which were £10 fully paid, were standing in the name of one, Pryor, as trustee for the Gulcher Company, and he transferred them, with other shares, to Messrs. H. R. Savory and Frederick Williams, in order to qualify them as directors of the New Zealand Syndicate, who, however, refused them registration. It was said there was some arrangement between the syndicate and the Gas and Water and General Investment Trust, Limited, by which the latter were entitled to three directors on the New Zealand Board, and that the shares in question were transferred by Pryor to Savory and Williams to qualify them for such directorate. The Gas and Water Trust had served notice that they intended to oppose these shares being transferred as was now asked.

Mr. Bramwell Davis, Q.C., now appearing in support of that notice, his Lordship, without proceeding further, adjourned the application to enable the notice of motion to be amended.

Western and Brazilian Telegraph Company.—The receipts for the past week were £3,116.

Digitized by Google

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Manchester.—The Lancashire and Yorkshire Railway Company require by the 30th April tenders for the supply of an oil-engine engine packing, signal and telegraph fittings, signal, telegraph and electric light wires, wire, etc.

Stowmarket.—The Urban District Council require by April 15 tenders for lighting the streets of Stowmarket from August 15 next to May 15, 1896, and also for lighting the post office clock. Particulars may be had of Mr. S. Prentice, clerk.

South Shields.—Tenders are invited for the supply and erection of a 10-ton hand-power overhead travelling crane at the Corporation electricity works. Copies of specification, including form of tender and general conditions, can be obtained at the borough electrical engineer's office, Waterloo-vale, South Shields, on and after 8th inst. Tenders, sealed, and marked "Tender for Crane," to be delivered to Mr. J. Moore Hayton, town clerk, Court Buildings, South Shields, by 10 a m. on 22nd inst.

Rangoon.—Tenders will be received by the president of the Rangoon Municipal Committee, not later than November 4, for the lighting of Rangoon by electricity. Tenders should be accompanied by detailed plans, specifications, and estimates, and must state the terms on which the installation proposed will be undertaken. All information regarding the existing system of lighting and the cost, etc., with plan of the town, can be obtained on application to Messrs. Ogilvy, Gillanders, and Co., Sun-court, 67, Cornhill, London, E.C., accompanied by a remittance of £1. 1s. Tenders are to be sent in sealed covers and endorsed "Tender for Electric Lighting, Rangoon." Mr. J. Short, Rangoon, is the secretary of the committee.

Brighton.—The Town Council invite tenders for the extension of the Corporation electricity generating station, North-road, comprising engine-room, boiler-house, coal stores, chimney shaft, and other works in connection therewith, for the Town Council. Drawings may be seen at the office of the borough engineer and surveyor, Mr. Francis J. C. May, M I C.E., Town Hall, Brighton, where specification, bills of quantities, and forms of tender can be obtained after 10th inst. upon the payment of £5. 5s., which sum will be returned on the receipt of a *bonâ fide* tender. Sealed tenders, addressed to Mr. Francis J. Tillstone, town clerk, Town Hall, Brighton, and endorsed "Tender for Extension of Corporation Electricity Station," must be left at the town clerk's office before 10 a m. on 25th inst.

Birkenhead.—The Corporation invite tenders for the erection and completion of a brick chimney 124ft. high above concrete bed, and for the construction of the necessary foundations thereof, in connection with the electric light station. Plans, specifications, and particulars, with form of contract, can be seen, and (upon deposit of the sum of £1. 1s., which will be repaid upon receipt by the Corporation of a *bonâ fide* tender) bills of quantities, with form of tender, can be obtained, on application at the town clerk's office, Town Hall, Birkenhead, or at the office of Mr. James N. Shoolbred, M.I.C.E, Albany-buildings, 47, Victoria-street, London, S.W. Tenders, which must be on the prescribed form, sealed and endorsed "Tender for Erection of Chimney," must reach Mr. Alfred Gill, town clerk, Town Hall, Birkenhead, by 12 noon on 22nd inst.

RESULTS OF TENDERS.

Brighton.—The Town Council have accepted the offer of Messrs. Crompton and Co., Limited, to supply two new armatures for the steam dynamos for the sum of £426.

York.—The tender of Messrs. Scott and Mountain has been accepted for providing an engine and dynamo for an electric light installation at the new sewage works at Fulford, for the City Council, at £157. 10s.

Bradford.—The Town Council have accepted the tender of Messrs. Siemens Bros. and Co., Limited, for supplying and fixing at the electricity works two 300-h p. engines each coupled with a Siemens dynamo, for £3,980.

South Shields.—At the Council meeting held on the 3rd inst. the tender of Mr. W. H. Brown, amounting to £3,124. 15s., for erecting the buildings in connection with the central station was accepted. The buildings have been designed and the specification for the work prepared by Mr. Jeckell, the borough electrical engineer, whose original estimate for the work was £3,100. Mr. Fred Rennoldson, South Shields, prepared the bills of quantities for the contractors.

Appointment Vacant.—A working foreman engineer is required for the London County Asylum, Claybury, Woodford, Essex, to take charge under the asylum's engineer of the whole of the engineering appliances, which include the heating system, electric light installation, laundry machinery, and cooking apparatus. He must be a thorough mechanic, able to control men, and with some experience of electric light plant. Salary £156 per annum, with house, coal, and gas. Persons desirous of applying must write, enclosing a stamped envelope, to Mr. R. W. Partridge, clerk of the Asylums Committee, 21, Whitehall-place, S.W., for an application form, upon which the conditions of service and other particulars will be stated. All applications must be delivered by 9 a.m. on 22nd inst.

BUSINESS NOTES.

Aberdeen.—Mr. A. S. Blackburn has written to the Town Council accepting the appointment of electrical engineer.

Dewsbury.—A meeting of the Town Council was held on Tuesday, at which it was agreed that the new baths and library be fitted throughout for electric lighting.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 7th inst. amounted to £1 024, as compared with £691 in the corresponding week of last year.

Halifax.—The Town Council have decided that application be made to borrow £5,000 to complete the original scheme of electric lighting, and £5,000 for additional electric lighting plant and extensions.

Hastings.—A new transformer-chamber is to be constructed under the public pavement at the junction of Norman road and London-road by the Hastings and St. Leonards-on-Sea Electric Light Company.

Burton.—The Gas and Electric Lighting Committee of the Town Council have recommended that the electric lighting main should be extended to Ashby-road and Alexandra-road, and the recommendation has been agreed to.

Northampton.—It was stated at a meeting of the Town Council that the electric light company had been requested to send in an estimate for four lights to be placed in the Market-square, but that they had not yet sent the estimate.

Anglo-American Telegraph Company.—The directors have declared quarterly interim dividends of ½ per cent. on the ordinary stock and of 1 per cent. on the preferred stock. The sum of £6,000 is to be transferred to the renewal fund.

The Britannia Company.—This Company are now opening an electrical department at 100, Houndsditch, E.C., in connection with their Colchester works, for all kinds of electrical work, more especially for electric lighting and transmission of power.

Indo-European Telegraph Company.—The directors recommend a balance dividend of 17s. 6d. per share and a bonus of 20s. per share, making a total of 10 per cent. for the year ended December 1 last. The sum of £10 000 is to be placed to the reserve fund.

Great Northern Telegraph Company of Copenhagen.—A final dividend of 7s. 2d. per share is recommended by the Board for the year 1894 together with the addition of £83,333 to the reserve and renewal fund, leaving £43,170 to the credit of the current year.

Eastbourne.—At the last meeting of the Town Council it was ordered that the common seal be fixed to the agreement between the Eastbourne Electric Light Company and the Corporation as to the laying of electric light wires, mains, boxes, etc., in the public footpaths in the borough.

Liverpool.—A meeting of the Special Lighting Committee of the Corporation was held on Monday, at which there was a discussion regarding the terms to be offered for the purchase of the electric supply company. It is understood that the sum of £400,000 was mentioned as the price to be offered.

Epstein Accumulators—The contracts for the central-station batteries for the Kensington and Knightsbridge Electric Lighting Company, Limited, at Kensington Court, and for the National Electric Supply Company, Limited, at Preston, have been placed with the Epstein Electric Accumulator Company.

City and South London Railway.—The receipts of the Company for the week ended April 7 were £935, against £852 for the corresponding week of 1894, or an increase of £83. The total receipts for the current period of the present half-year are £13,583 against £12,887 in the corresponding period of 1894, an increase of £696

Littlehampton.—Mr. Henry Harben, of Hampstead, who has taken great interest in the North-West London Convalescent Homes fund for working-men, has decided to erect at his own expense a building at Littlehampton, to cost £20,000. The home will be lighted throughout by electricity. The work is to be put in hand forthwith.

Brighton.—The Lighting Committee of the Town Council have resolved to offer the receiver and liquidator of Messrs. Latimer Clark, Muirhead, and Co., Limited, £1,000 in settlement of all claims under the contract of that firm. The committee have also adopted rules for the admittance of visitors to the electricity generating station.

Ayr.—The Town Council met on Monday, when Mr. Hammond reported that satisfactory progress was being made with the electric lighting works, and that the cable had been laid in Mill-street and High-street. It was remitted to a committee, with powers, to get the light introduced into the Town Hall and the other principal town buildings.

Removal.—Messrs. H. M. Salmony and Co. inform us that they have removed from their temporary offices at 66, Basinghall-street, E.C., to premises at 61, Charing Cross-road, W.C. They have also taken extensive warehouses at Sandringham-buildings, Charing Cross-road, where they will keep a large stock of all kinds of electrical accessories. The firm are still manufacturing at Notting Hill as hitherto.

Digitized by Google

Shop-Lighting.—The business premises of Mr. H. Chadwick, clothier, etc., Westgate, Dewsbury, have just been lighted electrically. Mr. A. Richmond Turner, electrician, of Bradford-road, carried out the work. Messrs. Chadwick and Son have six arc lamps of 1,000 c.p. each—two outside to light the windows and four inside—also four 16-c.p. incandescent lamps. They are supplied with current from the Dewsbury Corporation mains.

Hull.—At a meeting of the Hull Town Council on the 4th inst., Dr. Holder, moving the adoption of the committee's minutes, urged that that portion recommending that specifications for the new engine, dynamo, boiler, and switches, instruments, etc., and that quotations be obtained, be approved. Several members spoke strongly in favour of keeping the work in the town, and it was suggested that tenders should be invited from local firms for such portions of the work as could be done in Hull.

Enlargement of Premises.—Messrs. Green and Treacher, manufacturing electricians and electrical engineers, of 77, Cannon-street, E.C., inform us that, owing to the increased demands for their manufactures, they are enlarging their premises at 77, Cannon-street with the view of holding a more varied stock to meet the requirements of their wholesale and retail customers, and that they will stock all materials for electric bell and telephone work, and also small and general fittings used on electric lighting.

Cheltenham.—At the last meeting of the Town Council it was stated by Mr. Norman that he hoped that during this week or the next the Council might be invited to see the machinery at the electric light station in motion. At the expiration of a month from the present time the Council would take over the works from the contractors, and then an opportunity would be afforded for the public to visit the station, which, so far as machinery and equipment were concerned, was equal to any in the country.

Llanrwst.—The question of laying down an electric tramway from Trefriw to Llanrwst Station came before the Board of Guardians at its last meeting. The chairman said that the committee appointed to meet the promoters had seen them; but Mr. Bircham (Local Government Board inspector) had been to see the ground, and had given the committee to understand that he was opposed to the project, and there had been no further discussion of the matter. Mr. Bircham attended, and explained his objections. No decision was arrived at.

Bangor (Ireland).—The Town Commissioners of Bangor have received a letter from the secretary of the electrical works, Belfast, stating he had learned that the Commissioners proposed to light the promenade with electricity. He would be glad to tender for the supply and erection of the entire plant, which, consisting of 12 lamps of 2,000 c.p. each, with gas-engine, dynamo, and everything erected complete, would cost about £500. The cost of running the lights would not be more than 1s 6d per hour and 250ft. of gas for engine.

Rand Central Electric Works, Limited.—This Company has been registered, with a capital of £300,000, to carry on the business of generators and distributors of electric energy for the purposes of light, heat, motive power, or otherwise, at the Witwatersrand, and elsewhere in South Africa; to supply electric energy to the mines and other properties situate in or near to the Witwatersrand and elsewhere; for the above purposes to enter into and carry into effect two agreements expressed to be made by this Company with Messrs Siemens and Halske, of Berlin, and to carry on the business of an electric light and power company in all its branches

Worcester.—At the last meeting of the City Council a resolution was adopted empowering the Electricity Committee from time to time to employ such staff for the electricity installation as they might find necessary. It was stated that the committee at present proposed to employ three electricians (at £110, £90, and £65 a year respectively), two juniors to take charge of the switchboards (at £39 each), three drivers (at £83. 4s. each), two firemen (at £72. 16s. each), and two labourers (at £63. 14s. each)—a total cost of £865. 12s. per annum. The staff would have to work 24 hours every day, and would consist of three shifts of men. This would be exclusive of Mr. Murray's salary of £250 as manager of the works.

Kidderminster.—At the last meeting of the Town Council the Improvement Committee reported a communication from Messrs. A. Dickinson and Co., consulting engineers, Colmore-row, Birmingham, to the effect that they had clients who were prepared to promote a provisional order for the construction of an electric tramway from Kidderminster to Stourport, commencing at the top of Comberton Hill, Kidderminster, and ending at the Swan, Stourport, and asking for the approval of the Council. The committee recommended that the town clerk be instructed to reply that, subject to the rights and interests of the Town Council being properly protected, they were disposed to give the scheme their favourable consideration.

Llandrindod Wells.—At the last meeting of the Urban District Council correspondence was read on the subject of the introduction of the electric light, from which it appeared that Messrs. Andrews and Preece, Bradford, who at one time were prepared to take the matter up, were now too busily engaged elsewhere to do so, but suggested Mr. E. Blakey as a competent electrician. It was decided that advertisements should be inserted in the electrical newspapers inviting firms who were disposed to take the matter up to communicate with the Council. It was considered advisable that the Council should obtain a provisional order to authorise electric lighting, and then make arrangements with a private company to carry out the scheme.

Plymouth.—The committee appointed to enquire into the working of electric light systems in other towns have prepared a detailed report of their investigations decidedly favourable to the introduction of the light into Plymouth. They, however, think that before the Town Council come to any decision in the matter, it would be desirable for a sub-committee to visit other large and successful installations in London and the provinces, and bring up a further report for the guidance of the Council. The Council at their last meeting, on the suggestion of the Town Clerk, decided that the consideration of the report of the Electric Lighting Sub-Committee be adjourned, and that the matter be referred back to the committee, with instructions to employ an expert, and obtain and present a full report as to the best method of proceeding and probable expense.

Southport.—Mr. Rienzi Walton has held an enquiry on behalf of the Local Government Board with regard to an application by the Town Council relating to the electric lighting system, which was put into operation last November. The present borrowing powers amounted to £28,000, of which they have already expended £18,746, leaving a balance of £9,254. Already more than 2 000 lamps are wired on the mains more than the generating plant could really supply, and the Electric Lighting Committee propose to extend the buildings and power of the station to meet the present growing demand, and to enable them to tap the residential district of Hesketh Park. The cost of this work is estimated at £21.250, and over and above the balance in hand they applied for power to borrow £12,000, in addition to £3,500 for street-lighting, making £15,500 There was no opposition to the application.

Acton.—Mr. T. Baker, of Leamington-park, has written to the Urban District Council offering to assist the Council by drawing up gratuitously a report on the probable cost of a public installation of electricity and the returns which might be expected if he were furnished with certain data. At the same meeting a letter was read from Messrs New and Mayne accepting the Council's terms for the transfer to them of the Council's electric lighting order, but suggesting that if the Council decided to adopt the proposed sliding scale a minimum price of £2. 10s. per lamp should be fixed. The chairman remarked that if a minimum price were fixed a maximum must also be decided upon. Mr. Poulton observed that he was sorry that Messrs. New and Mayne had accepted the Council's terms. After a long discussion it was decided not to agree to Messrs. New and Mayne's proposal as to fixing a minimum price, and to ask them to say definitely whether they would accept the Council's terms.

Eccles.—The Town Hall and Electric Lighting Committee reported to the Town Council meeting that they had resolved that Mr. S. V. Clirehugh should be offered the appointment of consulting electrical engineer to the Corporation, for the purpose of the preparation of a detailed scheme for electric lighting in the borough according to the directions of the committee; to get out the requisite plans, specifications, and quantities, and estimates of cost, upon which borrowing powers could be applied for and tenders obtained for carrying out the work; and to supervise the work if it should be carried out, providing the committee were at liberty, if they saw reason, to determine the engagement at any time. The committee also asked that they might be authorised to visit the electric light stations at Manchester, Altrincham, Wolverhampton, Reading, Kingston-upon-Thames, Ealing, Woking, and St. Pancras to inspect the works. After discussion as to the number of places to be inspected, the report of the committee was adopted, on the understanding that the first three places mentioned only were to be visited.

Dover.—The sub-committee reported to the Town Council at their last meeting that Mr. Whitlock, of the Dover Electricity Supply Company, had enquired which 10 of the 21 arc lamps the Council wished to remain alight all night, and it was agreed that the matter should be referred to the Castle and Town Ward Lighting Committee. The Deputy Town Clerk stated that they had not yet received a reply from the Board of Trade in respect of their request that an inspector should be sent down to test the wires and fittings. The Chairman said that he thought the Board of Trade would reply that they had no itinerant inspector, and then their next duty would be themselves to appoint an expert to inspect the works, dynamos, and everything appertaining to the installation of the light. He thought that it would be their duty, as much for the interests of the ratepayers as the company, to see that there was no risk of accident. He thought the Board of Trade was bound to appoint an expert to give them a certificate as to the work and as to its efficiency or non-efficiency. They had specially contracted themselves as undertakers, and had this power.

Salisbury.—The Town Council have received a report from the Electric Light Committee, in which they state that they have received a communication from the Board of Trade in reference to the application by the Salisbury Electric Light and Supply Company, Limited, for the consent of that authority to the grant to the company of a provisional order to supply the city with electric light. The proposed provisional order was considered and compared with the license issued to the company by the Board of Trade on December 6, 1894. The committee resolved to recommend the sanitary authority to offer no objections to the issue by the Board of Trade of the proposed provisional order, save that such Board be urged to insert therein the whole of clause 19 incorporated in the license, as also such portions of clause 20 as could be made applicable to a provisional order; further, that the Board of Trade be solicited to insert in the provisional order such words as they might deem desirable with a view to providing, as far as might be, against the danger arising from the accumulation of gas

Digitized by Google

in street boxes and the escape of current, as evidenced by accidents which had from time to time happened in London and elsewhere. The report was adopted.

Edinburgh.—The current for the electric lighting of Edinburgh was to be turned on last night at eight o'clock by Mrs. M'Donald, wife of the Lord Provost, and Princes-street was to be instantaneously illuminated. Arrangements were made to allow of the ceremony being performed in the Rutland Hotel, the necessary connection having been provided by a wire taken into the building. At the last meeting of the Town Council it was recommended that the special attention of the Gas Commissioners should be called to the matter of faulty gas-mains and service-pipes in view of the introduction of the electric light. Councillor Mackenzie remarked that the officials of the gas managers should not look for leaks with naked lights, as he understood they had been doing. The Electric Lighting Committee, however, were not under any apprehension in regard to the matter at all, as every precaution was being taken. Bailie Anderson thought this motion was a gratuitous censure on the Gas Commission, and an instruction as to how the men were to do their duty. As it was, the Commission had been very much concerned about the laying of the electric mains, and had been put to a great deal of trouble and expense owing to injuries done to their gas-mains. After some discussion the report was adopted.

Tunbridge Wells.—The Lighting Committee have reported to the Town Council that the electric light would very soon be ready for use. Alderman Delves wished to know how the town was to be lighted after midnight, if the light was to be extinguished at 12 o'clock. Councillor Wood, as chairman of the committee, said if the light were put out at midnight the cost would be about £10 or £12 per year per lamp, but if the light were kept in till the early hours of the morning the expense would be from £20 to £25 per lamp per year. Councillor Gower having pointed out the need of extra light in the Camden-road district, the report was adopted. On subsequent proceedings of the committee coming up for confirmation, Mr. Stone Wigg drew attention to the position of the arc lamp at the South-Eastern Railway bridge, High-street. He said in its present position it was an obstruction to traffic, and he moved that it be placed in a different place. Councillor Grover seconded the motion. Councillor Wood said the committee considered the position the best that could be obtained when they erected the lamp, but they would again consider the matter. With regard to the cost of lighting the streets by electricity, he said he could assure them that when the latter was laid on they would get ten times the light for the same money that they were now paying for gas. He likewise mentioned that the committee would consider fairly the request that had been made by inhabitants in Camden-road to have lamps erected there. The report was adopted.

Newington, S.E.—At the last meeting of the Vestry the clerk read a long report with regard to electric lighting. The General Purposes and Lighting Committee urged that the Vestry should obtain a provisional order, and thus prevent a company obtaining a monopoly for 42 years. The committee recommended, "That the provisional order promoted by the County of London and Brush Provincial Electric Lighting Company, Limited, be opposed, by the Vestry giving an undertaking to the Board of Trade to promote a provisional order in the next session of Parliament for supplying a competitive supply in the parish to that undertaken by the London Electric Supply Corporation." Mr. Smithers supported the recommendation. He said the provisional order would cost only about £200. After the order had been obtained there was no need for the Vestry to proceed under two years, and the Vestry elections would enable the ratepayers to express their opinions on electric lighting in the parish. Mr. Parker, L.C.C., said he should be very happy to support the proposal that the London County Council should grant a lengthy period for the repayment of loans raised for the purposes of electric lighting. He thought the Vestry should not allow a company to get a monopoly. At the same time they should take care before they went into a large scheme for electric lighting. He did not see why a vestry could not make electric lighting pay as well as a private company. After some further discussion, in which several members spoke of the advantages of electric lighting, the recommendation of the committee was unanimously adopted.

Newport (Mon.).—A meeting of the Town Council was held on Tuesday, at which a good deal of discussion took place on the electric lighting of the town. The sub-committee in charge of the matter recommended the staff necessary for the smooth running of the works. It was suggested that there be a works manager at, say, £180 per annum, an assistant manager at, say, £130, and mechanics for the night-load plant and others for the day-load plant. The salary suggested for the works manager at £180 was fixed upon the assumption that the installation would be worked to some extent under the supervision of the borough engineer, otherwise a more expensive man would be necessary. The total salaries proposed amounted to £950 per annum. Mr. Fred Phillips thought the salary of the general manager should be raised and the salary of the assistant lowered. Mr. R. Wilkinson said he had a protest of ratepayers in the shape of a memorial, numerously signed, against the expenditure of the Corporation. Touching the electric light, it pointed out that a sum of £229 odd had been spent in the travelling expenses of deputations. Mr. Mordey said the Council had that day passed a scale for the expenses of deputations—viz., first-class travelling and a guinea and a half per day. Alderman Moses (chair of the Electric Lighting Sub-Committee) said they had heard a good deal from the croakers and the prophets of evil, who had no other desire than to see the installation a failure, but up to the present there had been no failure whatever in any of the plant, but, on the contrary, everything had been a great success. The Corporation had so far had applications for 2,000 8-c.p. lights, exclusive of the lighting of public buildings. The Corporation could not supply all the premises wired, because the wiring had not been carried out in accordance with the by-laws of the Corporation. As to the final completion of the works—for street-lighting as well as private lighting—he thought it might take place in two months, but he could not say definitely. But they would not run the large engines until they were thoroughly satisfied that they were in proper order.

Rochdale.—At the monthly meeting of the Town Council it was stated in the minutes of the General Purposes Committee that the sub-committee which had been appointed to consider the question of lighting the Town Hall, free public library, technical school, and other public buildings by electricity had recommended, on account of the heavy cost of lighting the Town Hall by electricity compared with the present cost, and the undesirableness of undertaking piecemeal installations, the postponement of any electric lighting until the Corporation determined upon a general scheme for lighting a section of the town. The General Purposes Committee had approved of the recommendation. Alderman T. Schofield, chairman of the committee, in answer to questions, said that the Corporation would not be able to bring the electric light from the sanitary works without first obtaining a provisional order from the Government, and in such a case they would have to state what area they intended to cover, and when they had got such an order they would be compelled to supply any tradesman who applied for a supply. The sanitary works were about three-quarters of a mile from the Town Hall, and they could imagine the expense that would have to be incurred if they decided to adopt the electric light. The cost of lighting the Town Hall would be two or three times greater than at present. It would be cheaper to provide an installation in the Town Hall itself. Again, the sanitary works were not situated in the centre of Rochdale, and it would be better to postpone any electric lighting until they determined upon a general scheme. Mr. Diggle said he was not satisfied with the report. He was confident that the extra power at their sanitary works could be utilised in lighting their public buildings by electricity. He moved that the Health Committee be requested to report at what price they could supply the electric light for their public buildings. Alderman W. J. Petrie, chairman of the Gas Committee, said he was very much in favour of electric lighting. After other members had expressed opinions on the subject, the amendment was lost, and the minutes of the General Purposes Committee were confirmed.

Dublin.—A deputation from the Dublin United Tramways Company waited upon the Pembroke Township Commissioners at their last meeting with reference to the proposal to use electric traction for their tramway system. Dr. Carte, chairman of the company, in introducing the deputation, said they felt confident of the Board's friendly interest in the company. Different systems of electrical traction for trams were in operation in different parts of the world. During last autumn a deputation from the company went to the Continent, and on visiting the principal places where electricity was used for trams they found that the overhead system was one of the most popular and useful. They therefore decided to apply this system on their trams and hoped to get the sanction of Parliament and the Commissioners for it. This overhead system would cause less obstruction of traffic than any other system, and the cleanliness of the streets would be much greater than with the horse traffic. In addition, it would give the public a more rapid service than at present, and would facilitate the public and benefit the township. At present the company only proposed to obtain electric traction for their lines from Nelson's Pillar to Clontarf, but they would afterwards introduce it on their other lines. The Commissioners had already given their sanction to an English company to work their trams to Dalkey by electricity, and the Dublin United Tramway Company would meet those trams and carry it to Dublin. Without their help the system referred to would not be effective. There was great competition from the railways, and he thought they should bring as much traffic into the township by giving the facilities which they asked for. The obstruction would be very trifling, especially in this township, where there was a straight line of road, and no curves or narrow streets. Mr. J. R. Wigham, a director of the company, said he was familiar with the application of electricity, and had very strong opinions on the overhead or trolley system as being the best devised for the propulsion of tramcars. By this system the cars were under most perfect control—more so than with horses. In reply to the chairman, Dr. Carte said they proposed to light the cars with electricity. The Chairman said the Commissioners were not yet in a position to give the deputation an answer to their application. They felt a great deal of anxiety to see how the system at present being constructed in the township would be carried on. The deputation then withdrew.

Bristol.—The following report dealing with the progress of electric lighting in Bristol has been presented to the Town Council by the Electrical Committee: "Your committee report that, after careful consideration of the present position of the electric light undertaking, they have determined to recommend the Council to sanction a moderate extension of the system for supplying electric current for private lighting. The Council are aware that the capital embarked in the undertaking amounts to £90,000, consisting of £16,000, the borrowing of which was authorised on March 10, 1891, for establishing the installation, and of £24,000, the borrowing of which was authorised on December 12, 1893, partly for paying off liabilities incurred in excess of the sum of £66,000 and partly for extensions of the system for private supply. By means of this expenditure your committee have been enabled to provide machinery and plant capable of supplying 34,000 lamps,

Digitized by Google

and to extend the system for private supply beyond the streets contemplated in the original scheme, to Guthrie-road, College-road, Clifton-park, Regent-street, Victoria-street, the Mall, and Portland-place, Clifton, and to Redcliff-hill. The number of lamps now supplied is 17,425, being only about one-half of the number which the existing plant is capable of supplying, and your committee consider that in order that the undertaking may become a source of profit to the Corporation every effort should be made to bring the output of electricity up to the full capacity of the plant, as the increase in revenue derived from the supply of current to additional lamps is largely in excess of the increase in the working expenses necessary to afford the supply. They also consider that it is important to obtain as customers the residents in private houses where artificial light is used during longer hours than in the case of shops. As the result of enquiries as to the localities from which the most profitable results may be expected, your committee have resolved to recommend the Council to extend the system for private supply to White Ladies'-road, Redland-park-road, Park row, Stoke's-croft, Clarence-road (St. Philip), and East-street (Bedminster) The electrical engineer estimates that the cost of laying mains in these streets, and providing the necessary apparatus, will amount to £8 000 and that £2,000 will be required, in addition, to connect new customers anticipated in streets in which mains are already provided. Your committee therefore recommend the Council to authorise them to arrange for borrowing the sum of £10,000 on the security of the district fund and general district rate."

PROVISIONAL PATENTS, 1895.

APRIL 1.

6622. **Improved mechanism for feeding the carbons in an electric arc lamp.** Archibald John Howard, Euston Villa, Cheddon-road, Taunton.

6630. **Improvements in automatic exchange systems and apparatus for telephonic and other electrical communication.** Ridley James Urquhart, 57, Barton-arcade, Manchester. (Ward Decker, United States.)

6649. **A system in connection with electric burglar alarms and other apparatus to which it is applicable.** Frank Terrey, 76 Royal-road, Kennington, London.

6652. **Improvements in the construction of electric accumulator plates.** Arthur Duffek and Bohumil Holub, 8, Quality-court, Chancery-lane, London. (Complete specification.)

6654. **Improvements in telephone transmitters.** Maxymilian Kotyra, 24, Queen Victoria-street, London.

6657. **Improvements in holders for incandescence electric lamps for stage and like purposes** George Lyons and Henry Bevis, 73. St. Stephen's road, Upton Park, London.

6674. **Improvements in asynchronous alternating-current motors.** Gustav Benischke, 4, South-street, Finsbury, London.

6681. **Improvements in or relating to electric switches or circuit controllers.** John Mathew Cronin, 18, Buckingham-street, Strand, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, 22nd September, 1894, being date of application in the United States.) (Complete specification.)

APRIL 2.

6756. **An improved mode of connecting the parts of a telephone apparatus.** Alfred Julius Boult, 323, High Holborn, London. (Parnell Rabbidge, Australia) (Complete specification.)

6781. **A socket for electric glow lamps.** The Edison and Swan United Electric Light Company, Limited, and Charles Faraday Proctor, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

6788. **Improvements in or connected with apparatus for recording and reproducing telephonic messages.** Robert Kirk Boyle, 4, South-street, Finsbury, London.

6791. **Improvements in and relating to dynamo-electric machinery.** P. R. Jackson and Co., Limited, Joseph Slater Lewis, and George Kemp, 31, High Holborn, London.

6795. **Improvements in enclosed electric mining switches.** P. R. Jackson and Co., Limited, and Joseph Slater Lewis, 31, High Holborn, London.

APRIL 3.

6893. **Improvements in electrical signalling apparatus for marine purposes.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Bradley Allan Fiske, United States.) (Complete specification.)

APRIL 4.

6908. **Improvements in electric weighing apparatus.** Henry Richardson, City Mill, Lichfield.

6934. **An improvement in electric glow lamps.** Henry William Handcock and Alfred Herbert Dykes, 5, Victoria-street, Westminster.

6935. **Improvements in and connected with junction-boxes for electric cables and the like.** Samuel George Dutton, 41A, Upper Manor-street, Chelsea, London.

6952. **A new or improved electrically opened and closed gas burner.** Eric Gustaf Rudén and Knut Leonard Norén, 18, Buckingham-street, Strand, London.

APRIL 5.

7009. **Improvements in dynamo-electric machines.** James Finlayson, 62, St. Vincent-street, Glasgow.

APRIL 6.

7075. **Improvements in and connected with electric cooking and heating grills and similar apparatus.** Thomas Fletcher, William Russell, and Fletcher, Russell, and Co., Limited, 70, Market-street, Manchester.

7086. **Automatic electric switch.** George William Russell, jun., and Alexander Vernon Officer, 52, Chancery-lane, London. (Complete specification.)

7107. **Improvements in working electric arc lamps and apparatus therefor.** James Brockie, 28, Southampton-buildings, Chancery lane, London.

7108. **Improvements in the purification of saccharine juices by electrolytic treatment, and means employed for that purpose.** Oliver Imray, 28 Southampton-buildings, Chancery-lane, London. (La Société Anonyme Raffinerie, Say, France. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1894.

5631. **Electric lighting of trains, etc.** Preston and Gill.

6046. **Electrolysis of saline solutions.** L. A. P. and H. E. A Liénard. (Second edition.)

6497. **Electrolysing chloride solutions.** Hermite and others.

8292. **Charging secondary batteries.** Liardet.

8350. **Electric batteries.** Leigh. (Vohwinkel.)

8972. **Secondary batteries.** Griffin.

10331. **Electric tram and rail vehicles.** Behr.

10515. **Dynamo brushes.** Fleming.

15403. **Telephones and microphones.** Krützfeldt.

1895.

1446. **Galvanic batteries.** Schoenmehl and Platt.

3095. **Electrical exchange systems.** Hey and Parsons.

3134. **Telephonic connections.** Hempel and Maerker.

NOTES.

Electric Traction in Brazil.—The *Jornal do Brazil* states that on Laderia de Santo Antonio work has been commenced on the Santa Theresa Electric Railway.

Healthy.—In his annual report, Dr. J. Clare, medical officer of Hanley, draws attention to the important fact, from a sanitary point of view, that the electricity works have been inaugurated during the year.

Electric Heating.—The non-technical papers are now taking up this subject. Thus *St. Paul's* of the 13th inst. contains an article by the Comtesse de Bremont on Messrs Crompton's electrical cooking and heating appliances.

Engineers' Tools.—The Britannia Company, of Colchester, send us a catalogue containing illustrated particulars of engineers', woodworkers', and amateurs' tools made by them. The company have likewise issued advertising 12in. and 9in. rules.

Robbery.—The premises of the Brush Electric Light Company, 49, Queen Victoria-street, were found broken open on Wednesday morning, and £300 is stated to be missing. It is believed duplicate or skeleton keys were used to effect an entrance.

Croydon County Polytechnic.—A special lecture was delivered at this institution last night (Thursday) by Mr. H. Byron Ransom, A.M.I.C.E., on "The Mechanical Principles of Electrical Engineering." A popular lecture will be given on Saturday next at the same place by Mr. A. Scholey on "The Applications of Electricity."

Books Received.—We have received from Messrs. Whittaker and Co., 2, White Hart-street, E.C., "Hydraulic Motors: Turbine and Pressure Engines," for the use of engineers, manufacturers, and students, by Mr. G. R. Bodmer, A.M.I.C.E. (second edition), and "The Steam Jacket," by Mr. William Fletcher (second edition).

Birmingham Technical School.—A new technical school in Suffolk-street, Birmingham, is approaching completion. On the first floor is the physics department, with a large lecture-room adjoining, the chemistry lecture-room, and the electrical engineering and telegraphic laboratories, the dynamo-room, and an apartment for applied physics.

Engineer Volunteers.—During the Easter Volunteer manœuvres, one of the works carried out at Chatham by the East London was a wire entanglement just in front of which a series of small mines were contrived, so connected by electricity that the whole would be exploded at once by the first enemy whose foot got entangled in or tripped over a wire.

Comparisons are "Odorous."—A meeting of the Cleaning and Lighting Committee of the Edinburgh Town Council has been held, at which it was resolved to recommend that in future none of the street gas lamps should be turned out at midnight in order to make the contrast between the gas-lighted and electric-lighted portions of the city less conspicuous.

Institution of Electrical Engineers.—The next meeting will be held at the Society of Arts, John-street, Adelphi, W.C., on Thursday, 25th inst. A council meeting will take place at 7 p.m., and the ordinary general meeting at 8 p.m., when a paper on "A Magnetic Tester for Measuring Hysteresis in Sheet Iron" will be read by Prof. J. A. Ewing, M.A., F.R.S., member.

Royal Institution.—On Tuesday next Prof. George Forbes, F.R.S., will deliver the first of a course of three lectures at the Royal Institution on "Alternating and Interrupted Electric Currents." The Friday evening meetings will be resumed on April 26, when Dr. John Hopkinson will deliver a lecture on "The Effects of Electric Currents in Iron on its Magnetisation."

Society of Arts.—The arrangements for the week ending April 27 are: Monday, April 22, at 8 p.m., Cantor lecture on "Recent American Methods and Appliances Employed in the Metallurgy of Copper, Lead, Gold, and Silver," by Mr. James Douglas (Lecture I.—Mechanical Appliances and Methods in American Metallurgy); and Wednesday, April 24, at 8 p.m., "The Use of Electricity for Cooking and Heating," by Mr. R. E. Crompton, Pres.Inst.E.E.

South-West London Polytechnic. — The new South-West London Polytechnic, Manresa-road, Chelsea, is now rapidly approaching completion, and will, it is expected, be ready for opening at the commencement of the autumn. The governing body have decided to at once advertise for head teachers for the various departments at a commencing salary of £250 per annum. The selection will be made early next month, and the appointments will date from September 1. Forms of application may be obtained from the secretary at the polytechnic.

The Pacific Cable.—The *Times* correspondent at Ottawa says that Australian mail advices from official and private sources respecting the Pacific cable scheme have arrived. In all quarters the importance of the alternative line of communication is fully recognised, and its establishment, as suggested by Canada, is meeting with favourable consideration. Some Governments have already affirmed the principle of State ownership. No valid objection is made by any of the colonies, and the hope is expressed that the home Government will take action soon.

Electricity in Warfare.—The Philadelphia correspondent of the *Times* states that after several years' labour the United States Government has completed on Sandy Hook, for the defence of the entrance to New York Harbour, a sunken mortar battery 500ft. square, enclosed by a counterscarp wall 20ft. high, having a ditch on the inside. Mortar pits are placed at each of the four corners of the earth embankment on the inside, each pit being furnished with four mortars. The pits are connected by subterranean galleries. These 16 mortars, which are worked and fired by electrical devices, each throw a projectile weighing 1,000lb., with a charge of 80lb. of powder, a distance of over six miles.

Exhibition at Croydon.—An electrical exhibition has been held by the Whitgift students in the schools in George-street. It included drawings of electrical apparatus, and apparatus such as for electrolysis of water, simple sounder and single needle telegraphs, fire alarms, telephones, and a burglar alarm working continuous-action bell, fitted up by present students. A lecture on electricity, illustrated by experiments, was given by Mr. J. N. Densham, the head student. Mr. H. T. Haws spoke on the education of an electrical engineer, explaining how to tell whether a boy was fitted to become an engineer, and how to enter the profession, winding up with a few remarks on the subject of lightning conductors.

North-East Coast Institution of Engineers and Shipbuilders.—The eighth general meeting of the session will be held in the lecture hall of the Sunderland Literary Society, Fawcett-street, Sunderland, on Wednesday, April 24, 1895, at 7.40 p.m. The following is the business: (1) Minutes of the last general meeting will be submitted for confirmation; (2) the discussion of Mr. S. O. Kendall's paper on "Turret-deck Cargo Steamers" will be resumed; (3) paper on "The Metric System of Weights and Measures (a plea for its adoption in the United

Digitized by Google

Kingdom)," by Mr. G. H. Baines; and (4) discussion. The closing business meeting of the session will be held in Newcastle-upon-Tyne on Tuesday, May 14.

Railway Appliances.—The United Kingdom section of the Imperial Institute is to be augmented during the approaching summer season by an exhibition of railway appliances and inventions. The International Railway Congress, which is to be opened by the Prince of Wales in June, has supplied an opportunity for displaying the capabilities of important branches of British industry connected with the railway services of the country, and the executive council of the institute have undertaken the necessary arrangements. The exhibition will be located in special buildings in the south-east quadrangle of the institute, and several of the leading manufacturers in the United Kingdom will be represented. Many of the exhibits will be shown in motion.

Personal.—Mr. C. M. Van Cüylenburg, of Singapore, who has been home on 15 months' furlough, has whilst here gone through a course in electrical engineering under Mr. Fred. H. Taylor, M.I.E.E., of Ironmonger-lane. He is an officer of the Public Works Department of Singapore. In order to advance with the times, Mr. Cüylenburg has qualified himself in what is acknowledged to be a very necessary adjunct to the duties of an engineer. The governor's house and the residence of the colonial secretary in Singapore are at present lighted by electricity, and not long ago the subject of lighting Singapore electrically was discussed in the local Municipal Council on the initiative of Major McCallum, but owing to the short-sightedness of some of the Commissioners, and a want of spirit in advancing with the times, the project fell through.

A Curious Theory.—A person signing himself "Ratepayers" writes to an Aberdeen paper as follows: "I observe from your columns that the Gas Committee of the Town Council received a deputation representing some consumers of electricity for business purposes complaining of the cost of the electric light, and the committee promised to supply them at about 50 per cent. less than they are doing to ordinary consumers. As a fairly large consumer and as a ratepayer, I object out and out to this unless the charge is reduced to all, which would be consistent and business-like if it is possible to produce it at the price. I hold that every ratepayer is entitled to have it at the lowest rate the Town Council can profitably produce it, and they may depend upon it that those who are consuming it daily will not stand by and permit them to supply it to any section of the trading community at a lower price."

Electric Lighting in India.—In the course of an article on the electric light and transmission of power stations at the works of the Manokji Petit Manufacturing Company, of Bombay, the *Indian Engineer* says: "A noteworthy feature of the electric installations we have been describing consists of the fact that the machinery is wholly supplied by the two firms of which Messrs. Nowroji Wadia and Sons, of Bombay, are the sole agents in India. A firm of agents which practically tests the machinery it imports under the altered conditions, as to climate, etc., in India, deserves well of the public. The secret of success of electric lighting in India in the future lies in a nutshell. Machinery of a superior type and fitting these up under trained supervision are the two essential elements of success in the industry, and an effort by any firm in India in these directions ought to be noticed and encouraged, with as much readiness as the opposite practice should be firmly dealt with and put a stop to by public opinion among the profession."

E.P.S. Accumulators.—The Electrical Power Storage Company have, as noted in our last issue, brought out a new catalogue of accumulators. Among the new developments of the E.P.S. storage cells we note the two types which are specially intended for carriage lighting, mine exploders, etc., where a high discharge rate and good capacity should be combined with low weight. The two types have, we understand, been largely taken up by the Admiralty for electrically firing guns, etc. The capacity of these cells per pound is practically the same as for the ordinary types, while the discharge rate per pound is at quite double that of any other type in the catalogue. When one remembers the great fall in capacity of the commercial storage batteries for abnormal rates of discharge, the great improvement in the two types will be readily seen. The prices of most of the older types have been reduced by 15 per cent., so that a kilowatt for seven hours can now be obtained from accumulators costing £32. 10s. (list price). The catalogue is now conveniently arranged for quickly referring to any particular type.

Electric Lighting at Ballarat.—The *Melbourne Argus* states that Ballarat has been illuminated by electricity. A number of schemes had at various times been considered to that end, and as long as 15 years ago a Melbourne company brought a steam engine there, and depositing it in the vicinity of the Town Hall reserve started on an undertaking involving the lighting of the city. The struggle for existence, however, was brief. The venture was more seriously taken up about a year ago by a number of leading citizens, and the Ballarat Electric Supply Company was formed soon afterwards. Since then 44 arc lamps of 3,000 c.p. have been placed in the principal streets and at the railway station. The work was carried out by Mr. J. A. Dawson, electrical engineer of the School of Mines, under the supervision of the Crompton Electric Lighting Company. The plant includes a right and left Tangye engine, each of 50 h.p., and a boiler of 100 h.p., and is sufficient to supply 500 additional incandescent lamps on the three-wire system, and orders for more than half that number have been received already.

Belfast Exhibition.—The contract for the whole of the electric lighting of this exhibition was placed in the hands of Messrs. Coates and Son in December with instructions to supply 1,000 incandescent lamps of 16 c.p. each and 100 arc lamps of 2,000 c.p. each, thus making the largest contract for electric lighting ever given to an Irish firm. Messrs. Coates's engineer, Mr. Stanley Dashwood, has designed and carried out the installation. Starting from one end of the installation, there is a boiler made by Messrs. Victor Coates. Next to this is a 60-h.p. Victor Coates steam-engine driving by ropes a Holmes "Castle" dynamo. Next to this is a Tangye engine, and then side by side are engines built specially for exhibiting made by Messrs. Crossley Bros.; the Acme, by Messrs. Peter Birt and Co.; the Robey, by Messrs. Robey and Co., Lincoln; the Midland, by Messrs. Taylor and Co.; the Stockport engine, of Messrs. Andrews's make; and a Dick-Kerr engine. These engines are driving eight dynamos made by Messrs. J. H. Holmes and Co., Newcastle-on-Tyne. These were built specially for this work. The arc lamps in the building are of the Crompton-Pochin type.

New York Central and Electric Traction.—The *Financial News* says that, regarding the statement telegraphed from Buffalo that the New York Central management had determined to equip its Niagara Falls branch with electric power, President Depew said: "That matter is now under consideration. We learned that a

Digitized by Google

local company had been formed for the purpose of building and operating an electric railway between Buffalo and Niagara Falls, paralleling our own line. It naturally occurred to us that if a new company could build and equip an entirely new road, and run it by electricity at a profit, we ought to be able to profitably apply electric power to a railroad already built and equipped. The proper officers are investigating this subject, with a view to ascertaining its cost and the best methods to be adopted. Undoubtedly the Niagara Power Company, which is now in operation, could be of great assistance to us in making a change from steam to electric power. No definite conclusions have been reached, however." The Niagara Power Company, which has succeeded in utilising the tremendous power of the Falls of Niagara, is a strong corporation financially. Several of its stockholders are identified with New York Central interests. William K. and Frederick W. Vanderbilt hold large blocks of the stock. Mr. Twombly has a considerable amount, and Chauncey M. Depew, J. Pierpont Morgan, and D. O. Mills are also stockholders.

Electrolysed Sea-Water for Sewers.—The executive engineer of the Bombay Municipality has written a letter to the Municipal Commissioner for submission to the Municipal Corporation on the question of the use of electrolysed sea-water for sewers. After describing the system, he says: "In my humble opinion it would not be possible to introduce this system of disinfection on a large scale into the city except at a heavy initial outlay. It would be necessary to provide pumping and electric plant, and to lay a system of water-mains throughout the city, with a large recurring annual expenditure to work the pumping and electric plant and to maintain the water-mains. The executive engineer thinks that if a reliable experiment is to be made, the best place would be the Carnac Bundar nightsoil depôt. The total approximate cost of the whole installation would be Rs.60,000. It is, he says, for the Corporation to decide whether an experiment, which is to cost Rs.60,000 at first and a recurring monthly expenditure of Rs.1,312-8-0, should be made. I may state, however, that I doubt whether the value of an experiment such as this is worth the expenditure proposed to be incurred." In conclusion, he states that although as the Hermite system of electrical treatment is at present in its infancy, and much cannot be gained by an experiment in Bombay, there is no doubt that as the science advances, and more progress is made by experts in England and on the Continent, the invention will prove important and effective in carrying out the object sought to be obtained.

Crystal Palace School of Practical Engineering.—The certificates which have been gained by the students of the above school during the past term have been presented to the successful candidates by Mr. J. C. Hawkshaw, member of the council of the Institution of Civil Engineers, in the lecture theatre of the school. The report of the examiners stated they had much pleasure in bearing testimony to the degree of excellence which had been attained. They could not speak too highly of the work carried out in the pattern shop, while the work in the fitting shop was also worthy of high praise. Mr. Hawkshaw, before presenting the certificates, delivered a short address to the students, in which he reminded them of the advantages they enjoyed in being able to attend the course of instruction at the Crystal Palace School. It was an advantage which many older engineers who had had a hand in building up the profession had never experienced. He pointed out that it was not by books and teaching alone they could become engineers, but an acquaintance with outdoor work was absolutely indispensable, and they must not think, when they were on works in progress, that they could neglect this outdoor work. They should go daily round the work, see with their own eyes and note everything that was going on, for the better observers they were the better engineers they would make. He exhorted them not to think that the business of the engineer lay solely in designing, and that it was the business of the contractor to carry the design out without supervision. Mr. Hawkshaw then presented the certificates. The first in order of the students of the first year's course were:—Mechanical engineering: Mr. E. Byron and Mr. T. C. Hassirdjoglow (bracketed); drawing office: Mr. F. G. Brooker; pattern shop: Mr. W. T. Harbord; fitting shop: Mr. D. H. Slack. The certificates for the second year's course were gained as follows:—Civil engineering: first term, Mr. F. G. Motley; second term, Mr. C. W. Wales; third term, Mr. D. K. McMinn and Mr. F. B. Nicholson (bracketed); fourth term, Mr. G. Stirling. Electrical section: first term, Mr. L. de Ridder; second term, Mr. F. E. Skipwith. Colonial section: Mr. A. W. Redfern and Mr. W. Riddell.

Royal Meteorological Society.—At the meeting of this society on Wednesday evening, the 17th inst., which was held at the Surveyors' Institution, Westminster, Messrs. F. C. Bayard and W. Marriott communicated a paper on "The Frost of January and February, 1895, over the British Isles." The cold period, which commenced on December 30, and terminated on March 5, was broken by a week's mild weather from January 14 to 21, otherwise there would have been continuous frost for 66 days. Temperatures below 10deg. F., and in some cases below zero, were recorded in parts of England and Scotland between January 8 and 13, while from the 26th to the 31st, and from February 5 to 20, temperatures below 10deg. occurred on every day in some part of the British Isles. The coldest days were February 8 to 10. The lowest temperatures recorded were 17deg. at Braemar and 11deg. at Buxton and Drumlanrig. The mean temperature of the British Isles for January was about 7deg., and for February from 11deg. to 14deg. below the average, while the mean temperature for the period from January 26 to February 19 was from 14deg. to 20deg. below the average. The distribution of atmospheric pressure was almost entirely the reverse of the normal, the barometer being highest in the north and lowest in the south, the result being a continuance of strong northerly and easterly winds. The effect of the cold on the public health was very great, especially on young children and old people. The number of deaths in London due to diseases of the respiratory organs rapidly increased from February 2 to March 2, when the weekly number was 1,448, or 945 above the average. Rivers and lakes were frozen, the ice being more than 10in. thick. The frost will long be remembered for its effect on the water-pipes all over the country, in many cases householders being without water for more than nine weeks. As the result of enquiries, the authors find that mains have frozen which have been laid as low as 3ft. 6in. from the surface of the ground to the top of the pipe. It appears, however, that the nature of the soil had far more to do with the depth to which the frost penetrated than the intensity of the frost itself. From a comparison of previous records, the authors are of opinion that the recent frost was more severe than any since 1814. Mr. Birt Acres also read a paper on "Some Hints on Photographing Clouds."

An Important Enterprise in Mexico. — An interesting electric power installation is now under construction for the Cia. Anonima de Transmission Electrica de Potencia, located in the State of Hidalgo, some 100 miles north of the city of Mexico. The water is taken from

Digitized by Google

the Arroyo de Regla, a mountain stream having a minimum supply of 1,500 cubic feet per minute. A natural rock dam at a point in the canyon impounds the water sufficiently to admit of its being diverted by a cut through the bluff into a canal, which follows mostly the contour of the mountain, a distance of 1½ miles. This involved the cutting of seven tunnels, aggregating a total length of 1,200ft. through solid rock. From the terminus of the canal the water is carried to the power station through 1,700ft. of 30in. pipe, which affords a vertical head of 800ft., this being of varying thickness to correspond to the pressure at various points on the line, the lowest portion being made of steel ¾in. thick. The pipe line discharges into a receiver 40in. diameter by 75ft. long, with which the wheels are connected by lateral branches. This is made of flange steel plates ¾in. thick, tested to 700lb. water pressure, and weighs upwards of 50,000lb. The power station consists of five Pelton wheels 40in. diameter, of capacity of 400 h.p. each—direct connected to the same number of 12-pole three-phase generators running at a speed of 600 revolutions, delivering the current at a pressure of 700 volts; also two 24in. Pelton wheels, speeded at 1,700 revolutions, for running the exciters. The step-up transformers are wound for a ratio of 1 to 15, making the line potential a little over 10,000 volts at the generator end. There are three transformer sub-stations in which air-blast transformers are to be used. Pelton differential governors are attached to each wheel for purpose of regulation. This station is to supply power to the mines of the Rio del Monte Company, employing upwards of 8,000 men. The power is to be used for operating mining machinery, such as stamp mills, crushers, pumps, hoists, ventilators, etc. The mines of this company—said to be the richest in Mexico—are located within a radius of 20 miles, the maximum distance of power transmission being 23 miles, and the mean distance about 18 miles. Various other mines in the vicinity will also be supplied with power from this station, and the city of Pachuca also furnished with light.

The Nature of Electricity.—At the last meeting of the Boston (U.S.A.) Scientific Society, Prof. A. E. Dolbear presented a paper entitled "The Nature of Electricity." Prof. Dolbear first gave consideration to fundamental notions in physics, speaking of the phenomena and factors thereof, these being matter, ether energy, and motion; the properties of ether being that it is continuous, non-molecular, frictionless, elastic, and energised. The origin of electricity was next discussed, this being either from friction, chemism, or heat for its direct production or induction for its indirect production. Consideration was next given to the ether, which, with its properties, becomes the medium in which exist gravity, light, magnetism, and electricity. The definitions which have been given for electricity were then reviewed, it having been considered a form of energy, a form of motion, energy itself, a form of motion of matter, a form of motion of ether, etc. Edlund defined it as ether itself; Lodge thinks it to be a wave motion in ether; Roland considers it a property of matter; while Trowbridge assigns its place among the great unknowables. As to its origin, electricity must have some antecedent motion. When the face of the thermopile is heated, we know that vibratory motion is the condition for its appearance; while in the battery, chemical action is the source, and the heat equivalent of this is a measure of the electricity produced. In glass, wax, etc., mechanical friction produces it, and when a conductor is moved in a magnetic field and electricity results, this will stop on the cessation of the motion. In every case the mechanical motion turned into it is the antecedent, and the energy of the engine is represented by the electricity developed. From motion, then, results energy; and if it be molecular motion we call it heat; if ether waves, we call it light; if molecular exchange, we call it chemism. And all electrical action is motion between matter and ether. As a summary of his arguments, Prof. Dolbear brought forward the following propositions: Energy is an embodiment of motion in some medium and does not exist independently, while the so-called forms of energy are due to the different kinds of motion a body may have. Transformation of energy is a change from one kind of motion to some other kind. Electricity never appears except when some known form of motion of matter is antecedent, and continuity of motion is a logical and experimental necessity; hence electricity must be a condition of thing in matter or else a condition of things in ether.

Code Telegrams.—"W. B." writes to the *Times* as follows: "In the preface of the official vocabulary of words selected for use in code telegrams throughout Europe, compiled and issued by order of the International Telegraph Conference, Paris, 1890, the following sentence occurs: 'Pour la dissemblance typographique et télégraphique des mots entre eux, il a été adopté comme règle que *chaque mot doive différer de tout autre mot d'au moins deux lettres* et de trois signes élémentaires Morse.' It is further stated (presumably to prove how carefully the work of compilation has been performed) that three systems of checking the words were resorted to, in order to ensure the above results. I have just devoted a couple of hours to a cursory examination of the English words only in the official vocabulary. The following words are to be found therein:

Awful	and	Lawful	Drainage	and	Trainage
Awfully	,,	Lawfully	Fitness	,,	Witness
Awfulness	,,	Lawfulness	Gardening	,,	Hardening
Boasts	,,	Coasts	Gazier	,,	Glazier
Brawlingly	,,	Crawlingly	Hawkish	,,	Mawkish
Budging	,,	Fudging	Knightly	,,	Nightly
Burnish	,,	Furnish	Liability	,,	Pliability
Burnishing	,,	Furnishing	Lumpishly	,,	Mumpishly
Comelily	,,	Homelily	Singingly	,,	Stingingly
Dobber	,,	Jobber	Steamer	,,	Streamer

I have also come across many words whose telegraphic signals are most unsuitable for code telegraphy. I happen to have a practical knowledge of telegraphy, and I have devoted upwards of a couple of years to selecting a vocabulary of words for a private telegraphic code. The experience I acquired leads me to think that, if I checked the official vocabulary systematically, I should find it contains many hundreds of words which, from one cause or another, are unsuitable for telegraphic purposes. That such a vocabulary should be issued under the sanction of the representatives of the European States of the International Telegraph Conference reflects but little credit on the arbiters of the telegraphic communities of Europe. But that such an ill-selected vocabulary should be compulsorily forced upon the mercantile communities of Europe three years hence should be most strongly protested against without delay. The extreme importance of using a well-selected list of words for code telegrams is well known to everyone who has a practical knowledge of telegraphy. I believe that the next meeting of the International Telegraph Conference will be held in the course of the next few months. It is full time that the British Chambers of Commerce, whose interests are threatened and imperilled by the arbitrary law regarding the compulsory adoption of the official vocabulary in January, 1898, should take energetic measures to protect British trade. They should insist on a revised edition of the official vocabulary being issued, or the law regarding

Digitized by Google

its compulsory adoption being rescinded. In the event of a revised edition being issued, it would rest with the International Telegraph Conference of 1895 to atone for its shortcomings by making adequate provision for entrusting the work of revision to men who are qualified to compile a standard official vocabulary more worthy of the name than the one under remark."

The Falls of Foyers.—Mr. S. R. Crockett is a novelist. Novels require advertising. It is not a bad way to advertise a novel for the novelist to advertise himself by rushing into print in the dailies when an opportunity presents itself. Mr. Crockett, who is a Scot, has at once jumped at the chance presented by the *Daily Chronicle* in the article to which we referred last week. He writes: "I have read the article in the *Chronicle* on the proposed 'capture' of the Falls of Foyers with something like stupefaction. It has long been a subject of profane levity with the travelled foreigner that in this country we have many fine falls, only at most of them we have forgot to turn on the water! Hitherto, we have always been able to refer such cavillers to the Falls of Foyers, situated in the united parishes of Boleskine and Abertarf, and this combination of orthography and topography has invariably served to upset the scorner's chair. But now Foyers is to be 'piped' like Baku paraffin, and syphoned away—spray, rainbow, and all—to do work to the amount of so many foot-pounds per hour. And the end of it all is—aluminium. Well, we can always go and gaze at the rocks, at any rate. But, alas! no shilling will serve to send the boy up to turn on the water, as at a certain Welsh fairy glen renowned in story. It was a dry year when the visitor made his appearance. The proprietor was willing that he should gaze on the works of Nature. He stood before the falls. 'Now,' said the guide, 'it is a shilling if you please, and I will send up the boy to turn on the water!' If, however, the Inverness County Council listens to the tempter, here is an inscription ready made with which to span the arid rocks:

God made the Falls of Foyers.
The British Aluminium Company makes aluminium.

And above might be placed a painted metal rainbow. Indeed, the whole sad tale reads like Milton's account of the first temptation of Eve. It would, of course, be entirely misleading to suppose that there is any resemblance between the manufacturers of aluminium and the tempter—

Squat like a toad, close at the ear of Eve
Essaying by his devilish art to reach
The organs of her fancy, and with them forge
Illusions as he list, phantasms and dreams.

But there certainly is some analogy between the sleeping Eve—yet beautiful, guileless, innocent—and the Inverness County Council. The 'advantages' to the town are undoubtedly good to eat and pleasant to the eyes. But this thing once done can just as little be undone as the former. And it may be—though of this we are not positive—that the 'illusions, phantasms, and dreams,' all trifles light as air, may have some connection with aluminium, which I am informed is one of the lightest of metals, and, like man, made from clay. At all events, you, Sir, have undeniably a good claim to be that Ithuriel of the Spear who touched lightly the hidden shape and revealed its monstrous reality. Surely, even the memory of Robert Burns, who wrote a poem standing beside the falls in commemoration of their beauty, and of Christopher North, who justly declares them to be the most magnificent cataract, out of all sight and hearing, in Britain, might be enough to keep the Vandal at bay, and to let the sunshine continue to illumine the spray, in token that the Falls of Foyers shall not be destroyed while the world lasts.' Whether this is meant seriously or comically we do not pretend to know. If the latter, Mr. Crockett resembles the Scot of a certain story who "joked with deeficulty."

Electric Lighting in Glasgow.—A correspondent writes to a Glasgow paper as follows: "Apropos of the opening of the electric lighting station at Edinburgh on the 11th inst., this question presents itself to me—viz., what is the Glasgow Corporation doing towards the developing of the electric light department under it? A few of the principal streets have been lighted by arc lamps, and are no doubt an improvement and an advance in the right direction. The low-tension network for private distribution has also been spread over the north-western part of the city to a considerable extent, and when fully taken advantage of will, I have no doubt, tax to the load-limit the capacity of the generating plant at Waterloo-street. But looking at this subject from a ratepayer's point of view, what answer have we to the question, Does it benefit the city, and is it paying? In face of the great bridge scheme and the historic weir, one looks upon all such new ventures with a critical eye, and I am afraid, if truth were told, this department would be a white elephant, or if not white, certainly verging towards the colour of that profit-consuming creature. And that for a few reasons, principally lying in the fact that nothing is being done by the Commissioners to popularise its being used, and to keep the fact before the citizens that the electric light mains are in their vicinity; and, further, that during the summer months, when so little light is required, no means are used to encourage the use of the current for other purposes than lighting, thus causing three-fourths of the plant to stand useless. Now, at first sight these points may seem of little moment, and the latter may be satisfactorily answered to some enquirers by saying, what other result could you hope for? But let us look at the steps taken by other municipalities, and we find a characteristic difference. We find that every means is taken to popularise and keep before the public in whose vicinity the electric mains are the advantages to be gained by its adoption, and, further, that a special rate being fixed per unit for lighting, usually from 5d. to 8d. (in Glasgow 6d. per unit), when a current is used for motors, heating, or any other purpose other than illuminating, a large reduction is made per unit, generally from 3½d. to 4½d. being charged, current being registered through a different meter. One other advantage arising from the use of current for motors, elevators, heating, or ventilating, is that it is generally more in demand during daytime, when light is not so much in demand, and a supply can readily be given for this work without interfering in any way with the lighting capacity of the plant in the evening. In George-street the gas department have a selection of gas cooking stoves, gas heating stoves, and various appliances designed for the use of gas, the hiring of which during the summer season must raise what would otherwise be a comparatively low gas consumption at that particular season. Similarly in another direction the market is stocked with appliances for the use of electric current, and are both more useful and cleaner in application than gas can ever be. But we look in vain for such productions from the Corporation warehouse. Therefore, I think one is justified in asserting that more can be done for this department to keep it in advance with the times, and that, instead of waiting until it is a failure, steps ought to be taken to give it an impetus in the direction of popularity and economic production, as it is evident the more steady the consumption of current the greater will be the saving. It is therefore to the immediate interests of the citizens that this be looked into."

THE PHOTOGRAPHIC TESTING OF PROJECTOR REFLECTORS.*

BY V. TCHIKOLEFF.

The military search-lights now used for lighting at great distances have reflectors of silvered glass, which have in principle considerable advantages over the metal reflectors and refractors formerly used. The fault of the Mangin reflecting refractors of glass used in France and other

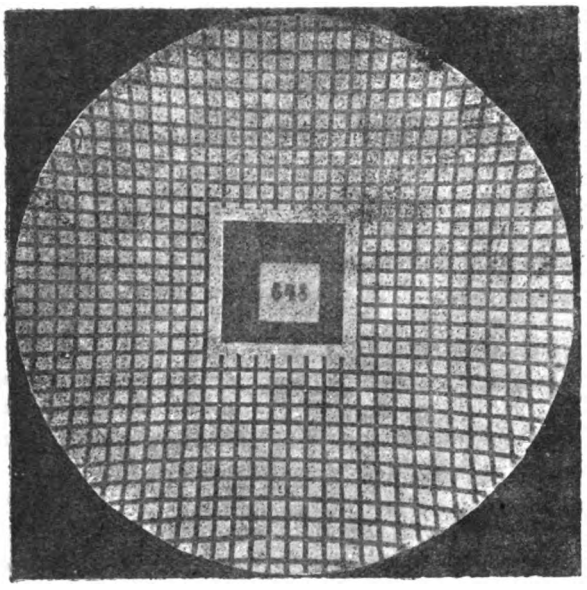

FIG. 1.

countries consists in the impossibility of constructing a parallel optical system when the focal length is less than two-thirds of the diameter of the reflectors. The spherical reflectors of silvered glass used in England, and even the arrangement designed by the author for use in Russia, have a considerable amount of aberration, and cannot be worked with a focal length less than five-ninths of the diameter of the reflectors. The glass parabolic reflectors made by Schuckert have a focal length equal to about one-third of the diameter.

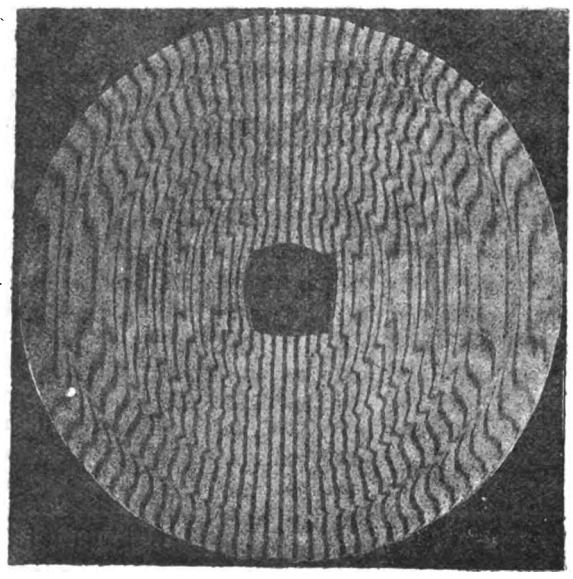

FIG. 2.

The Tchikoleff system of meniscus rings perfected by Siemens is the only one able to compete with the Schuckert reflectors, but the manufacture of apparatus on this system has been hindered by the defective construction of similar apparatus by Ratenau, which have not all the necessary accessories. In fact, the Schuckert reflector still remains the one for powerful lights, and can hold its ground provided the surfaces are made with sufficient regularity. The regularity of the spherical surfaces of the Mangin projector is assured by the method used in polishing it, while the regularity of the parabolic surfaces depends on the exactness of the lathe and on the workman.

The author from his experience considers that the Schuckert reflectors are not regular in outline, and that all differ more or less from the parabolic curves. As all the advantages of this reflector may vanish if the two surfaces (back and front) are not sufficiently regular, the author now considers the practical and certain means of controlling the regularity of these surfaces. His first idea was to use a spherometer of large size, but

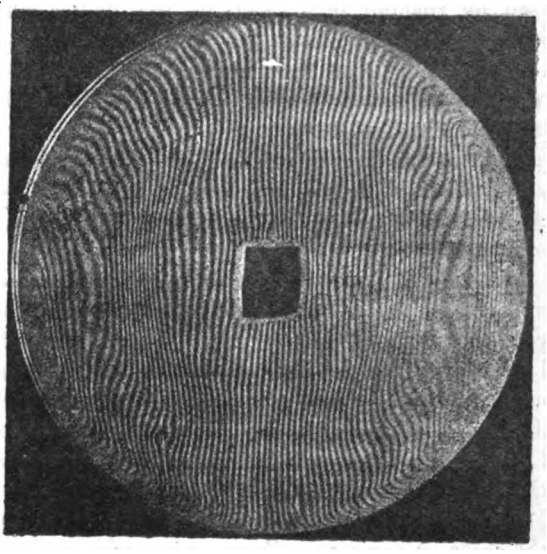

FIG. 3.

he had to give it up on account of the high price of an apparatus of this kind, and the accuracy of its construction could not be relied on. Even then the anterior surface of the mirror could be controlled by the spherometer. As to the posterior surface, the testing, etc., could not be conducted before silvering with the same instrument as before. The author had then recourse to an optical method. He placed a luminous point in the focus and studied the image reflected from different parts of the reflectors. This method necessitated the construction of

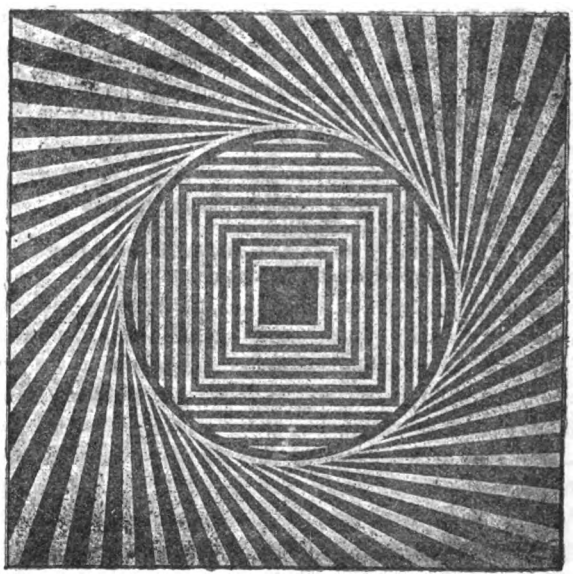

FIG. 4.

an envelope of wood for the projector, which must be capable of rotation round the same horizontal axis as the reflector, but independently of it. The difficulty of getting the two rotating bodies to revolve round the same optical axis has proved to be practically insurmountable, and at the same time to be very costly. In short, both methods have the following faults—that the difficulty of control is great, and that the results are based on subjective impressions, which give no record.

The author has devised another method, which consists

* *L'Eclairage Electrique.*

Digitized by Google

of photographing the image in the projector of a white screen covered with a black squared network. The results obtained thus are easily photographed when the screen is illuminated with an arc lamp. The first steps in the process are as follows: the reflector is removed from the lantern and placed at a distance of from 3ft. to 5ft. from the screen. This screen is of white material having a black squared network, the lines being ·2in. thick and ·6in. apart. In practice, at the centre of the screen a square opening is left (·8in. square) through which the photograph of the image of the network can be taken. The screen

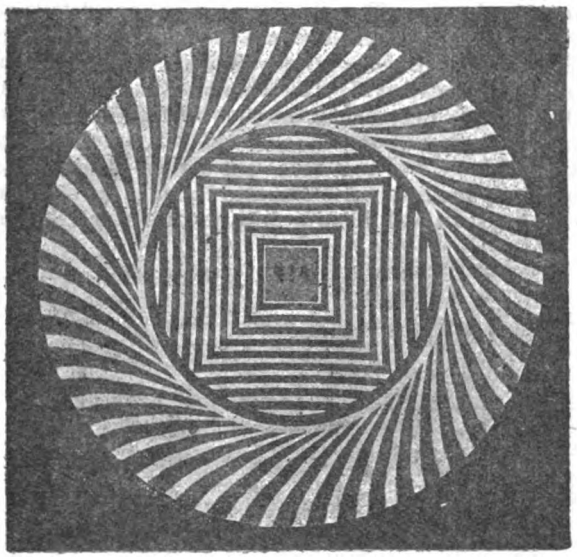

FIG. 5.

should exceed by 30 to 35 per cent. at least, the height and breadth of the projector. When the apparatus is arranged, it must be large enough to ensure that the image of the network covers the whole surface of the mirror.

The testing of the reflector is conducted as follows:

(1) The surface of the mirror in all planes is tried by a template to assure that, in general, the exterior curves of the surface are not far distant from the parabola. The uniformity of the thickness of the bed of glass, judged by

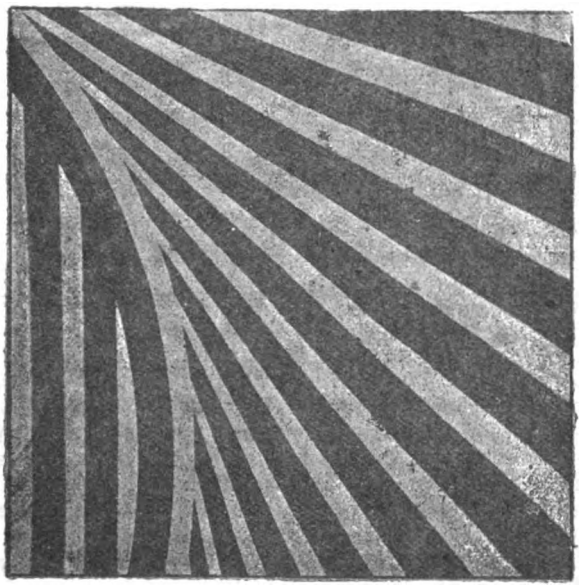

FIG. 6.

eye, allows of an approximate idea as to whether the two surfaces—interior and exterior—are parallel.

(2) The image of the screen on which the parallel lines are traced is photographed, which allows of the small defects on the surface of the reflector being observed.

(3) The image of the screen carrying the network is photographed. This better indicates the irregularities of the centre of the reflector, whereas the former test gives a better idea of the extremities.

(4) A photograph is taken of the projections of the electric light reflected by a reflector on the screen. Serious errors on the parabolic surface cause circles and dark spots. Small imperfections invisible to the naked eye can also be brought out by photometric processes, which augment the differences between light and dark.

In Fig. 1 we show a photo taken of a Mangin reflector 35½in. in diameter at a focal distance of 23·7in. Fig. 2 represents a parabolic reflector of glass very badly ground. Fig. 3 shows a metallic parabolic reflector hammered to shape, and then polished without grinding. An experi-

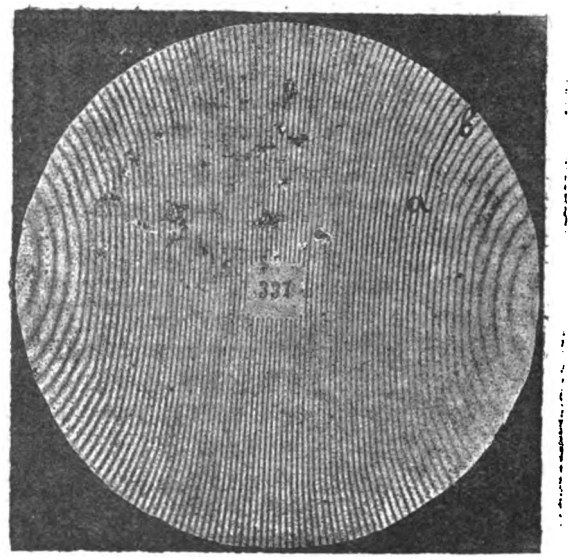

FIG. 7.

ment has also been made in photographing a screen image with tangential lines, as shown in Fig. 4. A similar figure presents this advantage, that all the lines are symmetrically and equally distorted. In Fig. 5 there is seen the image of the screen in a glass parabolic mirror. It will be noticed in Fig. 6 that the black rays are composed of three shades. This is the photograph of a portion of a mirror. The lightest part is due to the reflector on the front surface of the glass; the next to the reflector on the silver bed; and the darkest to the coincidence of the two. Figs. 7 and 8

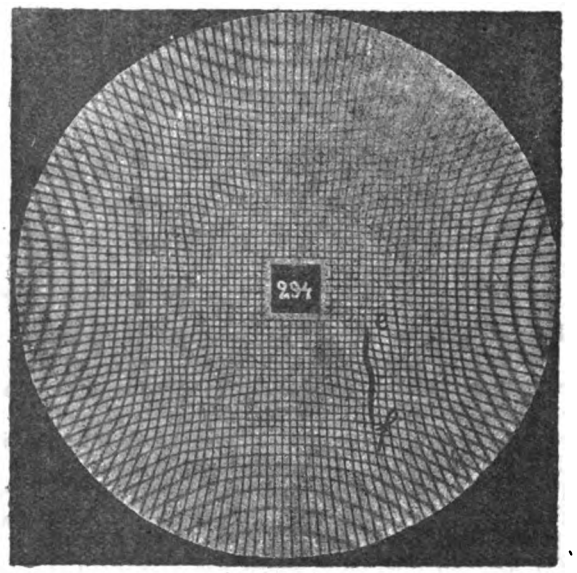

FIG. 8.

show the faults in a Schuckert mirror due to errors in grinding, etc.

ELECTRIC LIGHTING OF TRAINS.

BY R. W. WEEKES, WHIT.SCH., A.M.I.C.E

The question of the best system of electrically lighting trains is yet an open one, and the engineers in England have so far given more attention towards the practical

Digitized by Google

decision of this matter than any railway engineers abroad. The requirements of a perfect train-lighting system are as follows:

(*a*) The arrangement and subdivision of the light in the compartments should be convenient, and the candle-power sufficient to enable current literature to be read anywhere in the compartment.

(*b*) The voltage of supply must be steady, whether the train is running or not.

(*c*) Each individual carriage should contain its own source of electrical energy, to enable the train to be uncoupled anywhere or a carriage to be slipped.

(*d*) If the driving power for the dynamo is obtained from the axle of the carriage, the subsidiary apparatus to ensure constant potential at all speeds should be as simple as possible, and easy of adjustment and repair.

(*e*) All mechanical parts should be strong, and capable of standing vibration.

(*f*) The first cost should be reasonable.

(*g*) The working cost should compete with rival illuminants.

axles of the carriage has been largely used in this country. In America, Lieutenant I. N. Lewis has taken the matter up, and devised an apparatus which is described below. The great difficulty in all such arrangements is to ensure good regulation in spite of the great variations in speed of the trains. To this end, a number of automatic devices have to be used, and it will be interesting to compare our English practice with that of Lieutenant Lewis's. His apparatus consists of a dynamo fixed on the car truck itself, and flexibly belted to the car axle, which charges a storage battery of 12 cells carried under the car and at the same time, if necessary, supplies current for lamps in the car. The illustration shows the details of the connection between the dynamo and the car axle, and also the arrangement of the various circuits. The Lewis dynamo employed is one having a maximum output of 25 volts and 50 amperes. Rectangular carbon brushes are used, which are fixed in position. The machine is iron clad, being fitted with a close iron cover protecting the commutator, fields, and the brushes. Graphite bearings are used for the armature shaft and do away with the use of oil. FIG. 1.—Diagram of Lieutenant Lewis's Train-Lighting System.

It is needless to state that no present system is completely in accordance with the above, and I am sure that the engineers who have worked so long in the direction which they consider leads to that end will admit that their labours are not ended. The systems of electrically lighting of trains can be classified as follows:

(1) Lighting from accumulators placed in each carriage which are charged from a dynamo in the guard's van, which is driven from the axle of the carriage.

(2) Accumulators only, which are recharged at the end of the journey *in situ*, or removed and replaced by other charged cells.

(3) Direct lighting from a coupled plant, consisting of dynamo and high-speed engine supplied with steam from the locomotive boiler.

I propose to describe with sketches and diagrams examples of these various systems and their many variations, and, finally, to draw conclusions as to the direction in which the figures obtained from actually working them tend.

(1) The systems in which the dynamo is driven from the

is bolted to the bolster or truck beam, and connected by a raw-hide belt, 3in. wide, to a 20in. pulley on the axle, the armature shaft carrying a 7¾in. pulley. The distance between pulley centres being small, the belt is kept tight on the armature pulley by a pair of spring idlers, consisting of two flanged pulleys, 4½in. in diameter, over which the belt runs, revolving in graphite bearings and held together by the spiral spring on each side with adjustable nuts.

The distinguishing feature of this system is the way the dynamo is wound, through which it is made self-regulating for all speeds, and gives a nearly constant potential at the battery terminals without employing any of the auxiliary regulating devices heretofore necessary in axle-driven dynamos to obtain this constant E.M.F. at varying speeds of the train. This regulation Lieutenant Lewis accomplishes by a reverse winding of the series coil, the current passing through this coil going in an opposite direction to that in the shunt; the latter is fed from the storage battery, and its circuit automatically opened by a switch on the end of the armature shaft in order to prevent waste of the battery current when the car is standing still. By this

Digitized by Google

means the E.M.F. does not vary more than a few volts, notwithstanding large variations in the speed of the train.

Next to the dynamo the important features of the system are the pole changer and the automatic cut-out. The former ensures that the charging current is always of the same polarity, and the latter cuts out or cuts in the storage battery when the dynamo voltage falls below or when it attains a specified amount, thus preventing the battery from discharging through the dynamo in the former case. Both of these are placed in a small box with a glass face, which may be put up anywhere in the car, as no attention is required.

The pole changer consists of an electromagnet in the form of a vertically pivoted lever, with contact brushes on one end, and through whose coils the armature current passes. The lever is so arranged as to be controlled by two other electromagnets receiving their current from the storage battery. Should the direction of the car be reversed, the reversal of the armature current would follow, the polarity of the lever would be changed, and it would be repelled from the magnet which formerly attracted it and attracted by the one which before repelled it; in the new position the lever would thus be forced to take, it would, by means of the brushes on its end, reverse the relation between the armature and storage battery poles, thus sending the current through the battery in the same direction as before.

The cut-out switch consists of a pivoted electromagnet connected to the storage battery circuit, facing another electromagnet through which the armature current flows. When the current in the latter attains a certain strength, the lever magnet is attracted against the face of a spring, thus making the charging current, which is broken when the current falls below the specified amount or is reversed.

The accompanying diagram, which shows the wiring of the car on Mr. Lewis's system, illustrates the several features above described. The battery in this case will furnish about eight hours' lighting when the car is stationary. This description is taken from a paper read by Mr. M. B. Leonard before the Association of Railway Superintendents in America, and other reference to this valuable paper will be made in the following articles.

The storage batteries which according to Mr. Leonard have been the most satisfactory are the chloride accumulators. The batteries are carried in a box under the car out of the way, which is pierced with holes to allow the gas evolved in charging to escape. With four or more cars they are fitted with a special form of switch which opens the charging circuit automatically whenever the battery is fully charged, thus preventing unnecessary drafts on the locomotive for power. As the apparatus does not operate until the train has attained a speed of about 20 miles an hour, no extra work is imposed on the locomotive in starting the train. The entire apparatus is entirely automatic in its operation, requiring no expert attention, except a periodical inspection at the terminal points, and has given excellent satisfaction on the Chesapeake and Ohio Railway, as well as on the car that has been running for some time on the Brooklyn Bridge in New York, where another one is about to be installed.

Analysis of the Lewis System.

It will be gathered from the above description that the regulation of the voltage is effected by demagnetising series coils. Mr. Leonard, as superintendent on the lines on which this system is being tried, considers this method satisfactory, and says that there is only a variation of a few volts. It is difficult to see how, in the first place, the dynamo can give constant volts. Assume that at 20 miles per hour the voltage current and field strength are normal, then at 60 miles per hour the field of the dynamo must be reduced to one-third of its normal value. It is obvious to any careful investigator of problems in dynamo design that this change can only be effected when the rising part of the characteristic curve is used. Even then a considerable change of current will be required to vary the field to this extent.

On looking through the diagram of connections, Fig. 1, it will be seen that the dynamo is working on to the accumulators and lamps in parallel. Hence a change in current cannot take place unless there is a change in voltage. This points to the fact that the apparatus cannot possibly give constant voltage, but that the pressure must rise with the speed. This is not a radical defect unless the variation is excessive. A similar argument can be applied to nearly all engine governors. In fact, a commercial governor which regulates the speed without more than 5 per cent. variation between no load and full load is an exceptionally good one.

Now, for lighting purposes a similar variation of 5 per cent. in the voltoge may give 50 per cent. variation in the light, and this would be objectionable. Of course, the designer of this system may have reduced the variations below 5 per cent. Without wishing to unduly criticise the design, I would also point out that working on the rising, and therefore unstable part of the characteristic curve, is always unsatisfactory where exact voltages are required. Again, we do not see in the diagram any device for reducing the pressure on the lamps when the accumulators are being charged in parallel with them. In fact, the connection would, if used with lead accumulators as in the block, give a variation of some 20 per cent. in the voltage. At speeds below, say, 15 miles per hour, the lamps are supplied at the discharging voltage of the accumulators, and at high speed they are subjected to the full charging voltage. The chloride accumulator may not give this variation, but I have no record of their charging and discharging voltages. This defect can be remedied by using automatic arrangements, as devised by Mr. W. Langdon for the Midland Railway Company.

The machinery had not been working more than six months when Mr. Leonard obtained the following figures, and hence they are likely to be too favourable to the system, as the repair bill will not have reached its normal value. He states that the cost of fitting up per carriage, having in it 12 lamps of 16 c.p., was £102. 10s., and that the cost of lighting it for 10 hours per day was 1s. 11¾d.

I propose at the end of my series of articles to compare in list form the costs of all the systems, and hence reserve comment on the figures till then.

(To be continued.)

PRACTICAL NOTES ON DYNAMO CALCULATION.*

BY ALFRED E. WIENER.

(Continued from page 397.)

49. *Dimensioning of Magnet Cores.*—The sectional area of the magnet cores being found by means of the formulæ and tables given in Chapter 48, their length and their relative position must be determined.

(*a*) *Length of Magnet Cores.*—In the majority of types the length of the magnet cores has a more or less fixed relation to the dimensions of the armature, and definite rules can only be laid down for such cases where the length of the magnets is not already limited by the selection of the type.

Two points have to be considered in dimensioning the length of the magnets. The longer the cores are made the less height will be taken up by the magnet winding; the mean length of a convolution of the magnet wire, and consequently the total length of wire required for a certain magnetomotive force, will, therefore, be smaller the greater the length of the core. On the other hand, the shorter the cores are chosen the shorter will be the magnetic circuit of the machine, and, in consequence, the less magnetomotive force will be required to set up the necessary magnetic flux.

Of these two considerations—economy of copper at the expense of additional iron, on the one hand, and saving in magnetomotive force and in weight of iron, on the other—the latter predominates over the former, from which fact follows the general rule to make the cores as short as is possible without increasing the height of the winding space to an undue amount.

In order to enable the proper carrying out of this rule, the author has compiled the following Table LXIII., which gives practical values of the height of the winding space for magnets of various types, shapes, and sizes.

* From the *Electrical World* (New York).

In bipolar machines, such as the various horseshoe types, in which the length of the magnet cores is not limited by the form of the field-magnet frame, the radial height of the magnet winding in case of cylindrical magnets varies from one-half to one-tenth the core diameter, according to the size of the magnets, and in case of rectangular or oval magnets is made from ·5 to ·15 of the diameter of the equivalent cross-section. For multipolar types, in which the length of the magnets is of a comparatively much greater influence upon size and weight of the machine, it is customary to set the limit of the winding height considerably higher, in order to reduce the length necessary for the magnet winding. For cylindrical magnets to be used in multipolar machines, therefore, the practical limit of winding height ranges from ·75 to ·2 of the core diameter, and for rectangular or oval magnets from ·75 to ·25 of the diameter of the equivalent circular area according to the size.

In case of emergency the figures given for rectangular cores may be used in calculating circular magnets, or those given for multipolar types may be employed for bipolar machines.

In order to keep the winding heights within the limits given in Table LXIII., the lengths of cylindrical magnets have to be made from three to one times the core diameter for bipolar types, and from one to half the core diameter for multipolar types; those of rectangular magnets from one and two-thirds to three-quarters the equivalent diameter for bipolar types, and from one and a quarter to two-thirds the equivalent diameter for multipolar types; and the lengths of oval magnets, finally, from one and a half to three-quarters the diameter of the equivalent circular area for bipolar types, and from one and a quarter to five-eighths the equivalent diameter for multipolar types.

In the following Tables, LXIV., LXV., LXVI., LXVII., the dimensions of cylindrical magnet cores for bipolar types, of cylindrical magnet cores for multipolar types of rectangular magnet cores, and of oval magnet cores respectively, have been calculated. In the former two of these tables the lengths and corresponding ratios are given for cast-iron as well as for wrought-iron and cast-steel cores; in the latter two for wrought iron and cast steel only. From Tables LXIV. and LXV. it follows that cast-iron cores are made from 20 to 10 per cent. longer, according to the size, than wrought-iron or cast-steel ones of the same diameter; the lengths of cast-iron cores of rectangular or oval cross-section can therefore be easily deduced from the figures given in Tables LXVI. and LXVII.

(*b*) *Relative Position of Magnet Cores.*—The majority of types having two or more magnets, the relative position of the magnet cores is next to be considered. In a great number of forms having the magnets arranged symmetrically with reference to the armature circumference, the exact relative position of the magnet cores is given by the shape of the field-magnet frame. In other types, however, having parallel magnets on the same side of the armature, diametrically or axially, the shape of the frame does not fix their relative position, and the distance between them is to be properly determined.

This is done by limiting the magnetic leakage across the cores to a certain amount, according to the size of the machine—namely, from about 33 per cent. of the useful flux, in small machines, to 8 per cent. in large dynamos.

The relative amount of the leakage across the magnet cores is determined by the ratio of the permeance between the cores to the permeance of the useful path, and the percentage of the core leakage is kept within the limits given above, if the average permeance of the space between the magnet cores does not exceed one-third of the permeance of the gap space in small machines, and one-twelfth of the gap permeance in large dynamos, or if the reluctance across the core is at least three to twelve times respectively that of the gaps.

The area of the cross section and the length of the cores being given, the reluctance of the space between them depends upon the shape of their cross-section and upon the

distance between them. In case of round cores the shape is given by the area of the cross-section, and the reluctance of the path from core to core in consequence only depends upon their distance apart, directly increasing with the same. The reluctance of the air-gaps is determined by the diameter and length of the armature, by the percentage of polar embrace, and by the radial length of the gap space, decreasing with the area of the gap and increasing with its length. The cross-section of the cores and the gap area both depending upon the output of the machine, have a more or less fixed relation to each other—varying with the type, the voltage, the speed, and the kind of armature—and the relation between the reluctance across the cores to that of the air-gaps can approximately be expressed by the ratio of the average distance apart of the cores to the radial length of the gap space. In dynamos with smooth-drum armature this ratio is made from 6 to 16, in smooth-ring machines from 8 to 20, and for toothed and perforated armatures the distance apart of the cores is taken from three to six times the maximum radial length of the gap space—*i.e.*, from three to six times the distance between pole face and bottom of armature slot. The following Table LXVIII. gives the average distance between cylindrical magnet cores for various kinds and sizes of armatures, the ratio of this distance to the radial length of the gap space, and the corresponding approximate leakage between the magnet cores, expressed in per cent. of the useful flux.

In case of inclined cylindrical magnets, the figures given in Table LXVIII. for the least distances apart are to be considered as the mean least distances, taken across the magnets midway between their ends. (Compare formula (131), chapter 39.)

In dynamos with rectangular and oval cores the leakage across, for the same distance apart, is greater than in case of circular cores of equal sectional area, increasing in proportion to the ratio of the width of the cores to their breadth. For rectangular and oval cores, therefore, the distance apart is to be made greater than for round cores in order to limit the leakage between them to the same amount, and the distance must be the greater the wider the cores are in proportion to their thickness. The following Table LXIX. gives the minimum, average, and maximum values of the ratio of the distance across rectangular and oval cores of various shapes of cross-sections to the distance which between round cores of equal sectional area effects approximately the same leakage in small, in medium-sized, and in large dynamos respectively :

TABLE LXIX.—Distance Between Rectangular and Oval Magnet Cores.

Ratio of thickness to width of cores.	Distance between rectangular and oval magnet cores as compared with that between round cores of equal area causing approximately the same leakage across.		
	Minimum (small machines).	Average.	Maximum (large machines).
1 : 1	1·0	1 0	1·0
3 : 4	1·05	1·07	1·1
2 : 3	1·1	1·15	1·2

1 : 7	1·4	1·65	1·9
1 : 8	1 5	1·75	2·05
1 : 9	1·6	1·9	2·25
1 : 10	1·7	2·1	2·5

In order to determine the proper distance apart of rectangular and oval magnet cores, the corresponding distance between round cores of equal cross-section is taken from Table LXVIII., in multiplying the radial length of the gap space by the ratio of distance apart to length of gap for the particular size of armature. The distance thus obtained is then multiplied by the respective figure found for the shape in question from Table LXIX.

50. *Dimensioning of Yokes and Pole-Pieces.*—(*a*) *Yokes.*—In bipolar types—the dimensions of the magnet cores being given by Tables LXIV., LXVI., or LXVII., Chapter 49, and their least distance apart by Table LXVIII., or LXIX., Chapter 49, thus fixing the length of the yoke, and the sectional area of the yokes being found from formula (137), Chapter 47—the dimensioning of the yoke consists in arranging its cross-section with reference to the shape of

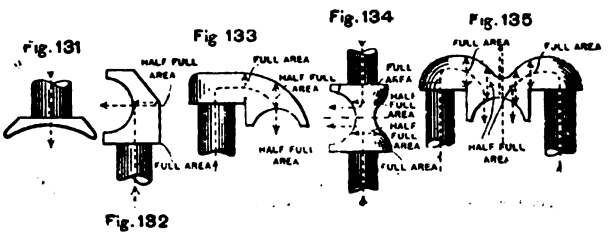
the section of the cores, and, for the case that its material is different from that of the cores, in providing a sufficient contact area, conforming to the rules given in Chapter 46.

In multipolar types the total cross-section found for the frame from formula (137), Chapter 47, is to be divided by the total number of magnetic circuits in the machine and multiplied by the number of circuits passing through any part of the yoke in order to obtain the sectional area required for that part of the yoke, otherwise the above rules also govern the dimensioning of the yokes for multipolar machines.

(*b*) *Pole-Pieces.*—In dimensioning the pole-pieces three cases have to be considered: (1) the path of the lines of force leaving the pole-pieces has the same direction as their path through the magnets, Fig. 131; (2) the path of the lines leaving the pole-pieces makes a right angle to that through the cores, Fig. 132; and (3) the path of the lines leaving the pole-pieces is parallel but of opposite direction to that through the cores, making two turns at right angles in the pole-pieces, Fig. 133.

In the first case, Fig. 131, which occurs in dynamos of the iron-clad, the radial, and the axial multipolar types, the shape of the cross-section is fixed by the form of the magnet core at one end and by the axial length or the radial width of the armature respectively, and the percentage of polar arc at the other, while the



height in the direction of the lines of force is to be made as small as possible, in order not to increase the total length of the magnetic circuit more than necessary.

In the second case, Fig. 132, met with in bipolar and multiple horseshoe and in tangential multipolar types, the height of the pole-pieces is determined by the diameter, and the length of the pole-piece by the length of the armature, while the area of the cross-section perpendicular to the flow of the lines is to be made of the size obtained by formula (137) at the end next to the magnet core, and to be gradually decreased in amount from that end to the opposite end or to the centre of the pole-piece respectively, according to whether there is but one magnetic circuit or whether two circuits are passing through the same pole-piece. Since in bipolar machines the lines of force are supposed to divide equally between the two halves of the armature, only one-half of the total flux passes the centre of the pole-pieces in order to reach the half of the armature opposite the magnets, and the area in the centre of the pole-piece consequently needs to be but one-half that at the end next to the core. In case the two circuits passing through each pole-piece, Fig. 134, the same applies to the cross-section of the pole-piece at one-quarter the height from either end. For ready use in Table LXX. the dimensions of wrought and cast iron pole-pieces for various sizes of bipolar horseshoe type dynamos are calculated for drum and ring armatures by combining the respective data given in former tables.

In the third case, Fig. 133, finally, which is found in single and double magnet types, the length of the magnetic circuit in the pole-piece is determined by the diameter of the armature, by the cross-section of the magnet core, and by the height of their winding space; the width parallel to the armature shaft of the pole-piece near the magnet is given by the width of the magnet core, and that near the armature by the axial length of the latter. The heights parallel to the axis of the magnet core, in case of a single circuit, are to be so chosen that all of the cross-sections up to that in line with the pole corner next to the magnet core have an area at least equal in amount to that obtained by formula (137), and that the section in line with the armature centre has an area of one-half that amount. In case of two circuits meeting at the pole-pieces (consequent-pole types), Fig. 135, the full area has to be provided from either end of the pole-piece to the sections in line with the pole corners, half the full area at quarter distance from each pole corner—that is, midway between each pole corner and the pole centre—and sufficient cross-section for mechanical strength only is needed at the centre of the pole-piece.

(To be continued.)

THE HOLOPHANE GLASS GLOBES.

These light dispersing and directing globes, manufactured on the Blondel and Psaroudaki system, are being introduced into this country by Mr. S. M. Scott. There is no point in the construction or principle of these globes which has not been understood for years, but by careful work on proved

Digitized by Google

theoretical lines a practical globe has been produced which gives most excellent results. The history of light-diffusing globes for arc and incandescent lamps is too extensive to be gone into here, but it has received a fair amount of attention in England.

The inventors of this new globe state that the great fault of the older dispersing globe was that a certain percentage of the light was turned back into the interior again by certain parts of the surface of the globe. This is illustrated in Fig. 1, where the ray of light striking on the

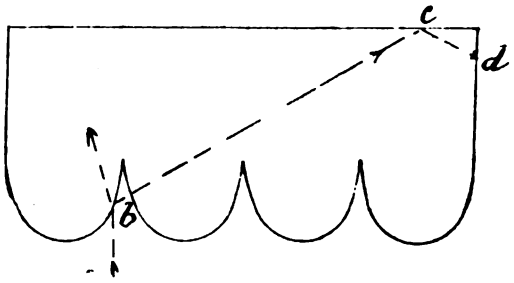


FIG. 1.—Old Type of Light Dispersing Flutings.

side of the V is reflected, and again refracted from the outer surface of the glass. In this way the light does not get out through the glass, as it should do. To get over this, Messrs. Blondel and Psaroudaki have abandoned the sharp angle at the bottom of the fluting, and use a concave flute instead. The pitch of fluting is smaller

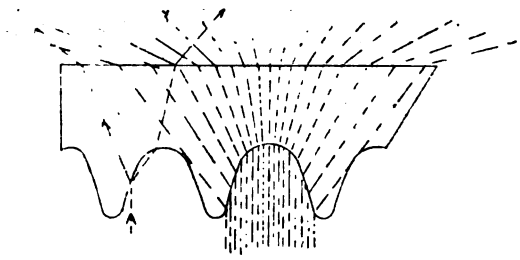

FIG. 2.—New Dispersing Flutings used in the Holophane Globe.

than that used in older forms of dispersing globes, and they endeavour to design the contour of this fluting so that none of the light is reflected or refracted internally. They have adopted a form of contour as shown in Fig. 2. This dispersing fluting is arranged on the inside of their globes. The next point is that they use the principle of

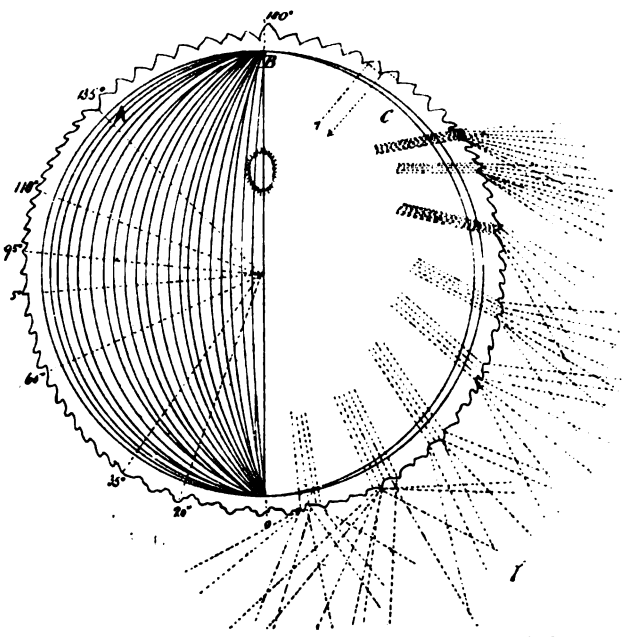

FIG. .—Section of Arc Lamp Globe showing Different Shaped Flutings.

the Fresnel lens system for the purpose of directing the light externally. To this end a series of horizontal flutings are made round the outside of the globe. The form of the fluting changes at different parts of the globe, so that each corrugation throws the light in approximately the same direction.

We had not the opportunity of testing one of these globes round an arc light, but on a high candle-power incandescent lamp the effect was most satisfactory. The upward rays from the lamp were practically all reflected downwards by the upper surfaces of the fluting, so that the ceiling above the globe was darker than any other surface in the room. When looked at from underneath the whole of the globe was lighted, and the great number of brilliant facets had a most pleasing effect. Tests made in Paris at the Central Laboratory of Electricity showed that the globes absorbed only from 9 to 13 per cent. of the light passing through them, and these figures are confirmed by tests made by the Edison Company in Paris.

The way in which the arc lamp globes improve the polar curves of candle-power has been shown by this last-named company from tests made on lamps placed in the Boulevard St. Denis, in Paris. The actual curves show that the globes have been accurately designed, with the object of giving as uniform distribution as possible over the space intervening between two arc lamps. The angle of maximum candle has been considerably elevated to this end.

The important question of manufacturing these globes and shades commercially to compete with existing types precluded the use of cut glass. After careful trials, the

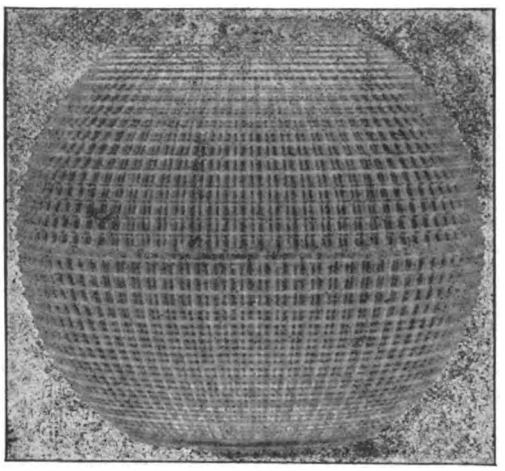

FIG. 4.

inventors have succeeded in getting their globe produced in pressed glass. The first cost of the necessary moulds having the different-shaped grooves is, of course, great, but this factor disappears when the globes are manufactured in quantity.

We illustrate a section of the arc lamp globe, Fig. 3, which shows the different forms of the fluting at different parts of the globe, and also indicates the transmitted and refracted rays of light. Fig. 4 gives the general appearance of this globe.

We understand from Mr. Scott that the globes will be placed on the market early in May at prices which should command business, and are sure he will be pleased to show them to anyone interested in the subject at his office at 35, Queen Victoria-street, E.C.

Electric Traction in France.—An electric railway is to be constructed from the Carrefour Cadet to the summit of Montmartre.—The report of the Continental Metropolitan Tramways Company, Limited, for 1894 states that the necessity for improving the means of communication in Paris has long been felt, but it has become much greater by the rejection of the scheme for a metropolitan railway, and in view of the approaching Universal Exhibition in 1900. There has consequently been a general movement amongst the tramway and omnibus companies in Paris for new lines, extensions, and improved methods of traction. The directors have, in accord with their Paris colleagues, decided that the interests of the company demanded the adoption of a similar policy. With reference to the substitution of mechanical for horse traction, this question is receiving the fullest attention of the directors.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

THE LIGHTING OF RAILWAY CARRIAGES.

The most interesting paper recently read by Mr. W. Langdon before the Institution of Electrical Engineers did not, as was hoped, touch on this most important question. We cannot deny that during the past few years great improvements have been made by railway engineers in the lighting of the trains under their charge, but unfortunately their efforts have in most cases been confined to main-line and express carriages. The class of passenger so catered for is an important one, and on a long journey the need of a good light is specially felt. Still, this is no reason why the needs of the local and suburban lines, which carry, perhaps, a hundred passengers while the main lines carry one, should be so neglected. After a busy day in town the light provided in the carriages of many of the local lines round London is irritating in the extreme. We usually find just enough light to read the headings of the articles in the evening papers, and that is all. At the stations you may stop just opposite a ten-candle-power gas lamp, which for the time being dims the internal lighting of the carriage and enables you to read a short way into an interesting article, which may, perhaps, be "continued at the next" station if the fates are propitious.

We do not doubt that the directors are more to blame than the engineers, but it is to the engineers that we must look for improvements. The fact that comfort in travelling leads to increase of traffic more than compensating for the cost of such extra comfort has been abundantly proved. In America, the great development of the tramway industry there following on the improved speeds gained by electric traction over horse traction, is a most remarkable instance of this. We do not suppose any "radical reduction" railway director would deny that the main-line traffic has been increased owing to improvements in speed, lighting, and general comfort, and yet he would continue to run antiquated carriages with one-candle-power oil lamps on local lines, which, as a rule, pay better dividends than main lines.

The question as to what is the best system of lighting for railway carriages from the directors' point of view we do not propose to discuss *in extenso* here, as we know that electricity is the best and safest illuminant for the purpose. We believe that it will prove also to be much the cheapest, light for light, when worked on a large scale. Still, we contend that even should it be dearer than other illuminants which are dangerous to the public safety and health, it will still more than pay for its cost by the additional comfort it gives. We honour the English railway engineers who have taken such a prominent lead in the development in the electric lighting of trains so largely in America. Amongst these we may specially mention Mr. E. J. Houghton, Mr. W. Langdon, and Mr. Ireland, all of whom have given much time and original thought to this subject. Others have ably assisted in the progress made. Nearly all the engineers in England have driven their dynamos from the axles of the guard's van. We are sure they have not done so on account of the popular idea

Digitized by Google

that it costs nothing for coal if so arranged, but the great advantage of this system is that on down grades the momentum of the train provides the necessary energy.

The great variation in speed has to be corrected by some device to ensure constant potential at the lamps. The many ingenious inventions with this object will form the matter of a series of articles commencing in this issue.

Other electrical systems have been tried in this country and elsewhere. We have full confidence that both the cost of upkeep and the capital charges will be considerably reduced in consequence of this competition, and that at least even the shareholders, who desire dividend before everything else, will be obliged to admit that electricity is the best light, the cheapest light, and the light they will have used on the lines in which they are interested.

THE ST. PANCRAS REPORT.

Although the representative committee of experts have given us some definite information as to the probable source of the alkaline deposits in the St. Pancras conduits, we regret that they have not given a more exhaustive report before concluding their labours. The fact that no free alkali was found in any of the samples submitted to Prof. T. E. Thorpe is of itself a curious admission in a report which attributes the explosion to the very substance their chemical expert did not find. Personally, we have no doubt but that such free alkalies have been found quite recently at St. Pancras, and why such samples should not have been immersed in oil and preserved for analysis we cannot understand. From a wood bearer which we have permitted to inspect through the courtesy of Mr. J. T. Baron, we have no doubt but that the greater portion of the alkaline deposit originates from the soil being introduced along the fibre of the wood in solution. Still, beside this, the glaze shows signs of disintegration, and is, we believe, a contributory cause. In fact, we understand that Prof. A. B. W. Kennedy has for years avoided the commercial glazes for this reason, and specifies that all earthenware used in the construction of his mains shall have a hard insoluble glaze. This precaution, although it may raise the price of the insulators slightly, will prevent any trouble arising from them. In conclusion, we can only repeat that a report on this most important subject consisting only of some two hundred words, is not what we should expect from a committee representing such wide interests.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ALKALINE DEPOSITS ON ELECTRIC LIGHT MAINS.

SIR,—We have read with interest the report by the special committee formed to investigate the cause of the alkaline deposit found on the electric light mains at St. Pancras. Several articles have appeared in the electrical journals attributing this deposit to the decomposition of the stoneware insulators. We fear that the tendency of such articles unfortunately may have been to create a want of confidence in a material very reliable and suitable for insulating purposes. We think it therefore of great importance that attention should be called to the finding of the committee of investigation, which proves conclusively that the deposit (which has been found on glass, brickwork, and wood, as well as on stoneware) is not derived from the insulators, and which entirely confirms the view we took in a recent letter to one of your contemporaries, in which we asked that "before the presence of the unwelcome sodium is attributed to 'decomposition of stoneware' those interested in the result should wait to see whether the investigation may not prove that the source is to be found, not in the insulators, but in the cement, the brickwork, or the surrounding soil."—Yours, etc.,

DOULTON AND CO.

Lambeth Pottery, London, S.E., April 17, 1895.

COST OF ARC LIGHTING.

With reference to our leader last week on this subject, we have had a communication from Mr. Raworth informing us that 2½d. per arc lamp hour was the price obtained from the North-Western Railway Company for lighting their Manchester station. We cannot remember at this distant date the actual cost of production.

ANSWERS AND SOLUTIONS TO THE QUESTIONS IN ELECTRIC LIGHTING AND POWER TRANSMISSION.

PRELIMINARY EXAMINATION, 1894.

1. Define the terms "in parallel," "in series," "on open circuit," and give sketches in illustration.

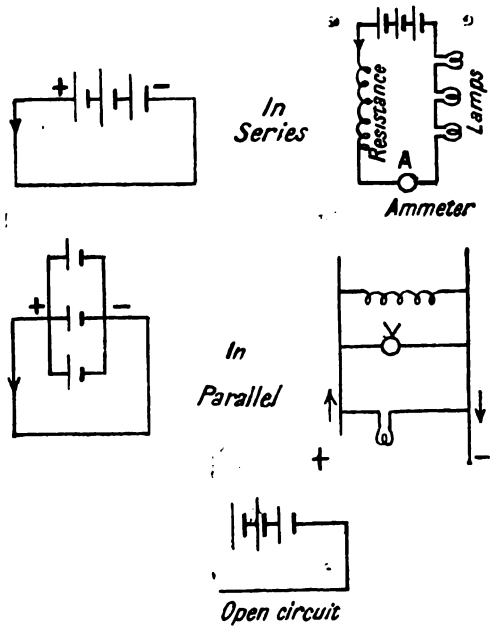
Answer 1.—The path traversed by an electric current is called an electric circuit, and it is obvious that it must at least be composed of two parts—*i.e.*, (1) the source, and (2) a conductor connecting the terminals of the source. Now, each of these parts may be composed of one or more separate parts. For instance, the source may consist of several cells and form a battery, whilst the conducting portion may include connecting wires, measuring instruments, and appliances worked by the current, and the terms "in parallel" and "in series" are used to indicate the methods of joining up the separate portions composing the circuit, according to the conditions of the case.

"In parallel" is defined as that arrangement in which all similar ends, terminals, or poles of the elements are connected to one conductor, and the other ends of the elements are connected to another conductor, so that the circuit is composed of several separate paths.

"In series" is defined as that arrangement in which the positive terminal of an element is connected to the negative terminal of the next element, and so on, so that the whole thus connected forms a series of parts, through which the same current passes.

"Open circuit" is defined as that arrangement in which the current is not able to pass into the conducting part of the circuit.

In the figures below the parallel lines represent graphically a battery; the short thick lines denote the zinc plates, and the long thin lines the negative plates.

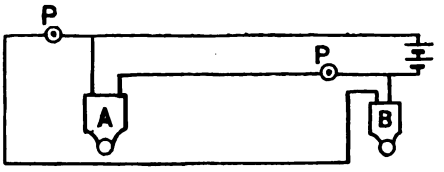


2. Describe the Leclanche cell, and add some hints as to how to maintain it in working order.

Answer 2.—The Leclanché cell is a zinc-carbon couple, the positive plate of which consists of a rod of amalgamated zinc, and the negative plate consists of a plate of carbon, which is fixed in a mixture of powdered peroxide of manganese and carbon, placed in a jar of porous earthenware. The two plates are placed in a glass vessel containing a saturated solution of chloride of ammonium (sal-ammoniac). In consequence of polarisation, which is very rapidly produced, the current is only continuous for a very short time, so that this cell is particularly well adapted for intermittent work, such as bell ringing. If allowed to rest, however, it soon regains its activity and strength, and as it does not deteriorate much when on *open circuit*, it will last for months without attention and renewal. Its E.M.F. is about 1·47 volts, and its resistance fairly high.

To maintain the cell in good working order it is necessary to add water from time to time in consequence of evaporation. Sal-ammoniac must also be added occasionally, as there is a tendency for the sal-ammoniac to gradually crystallise out and to creep up the sides of the containing vessel. For this reason it is advisable to cover the inside of the neck of the containing jar with melted paraffin wax. It should be kept in a cool, dry place.

3. Sketch the connections needful for bells between two places, A and B, so that a person at B can ring the bell at A, and that a person at A can ring the bell at B. One battery (of two or three cells) only to be used, and only one bell to ring at a time.



4. A lamp circuit is supplied at a pressure of 100 volts. There are 42 lamps, all in parallel, and the resistance of each lamp is (when hot) 150 ohms. How much current will the circuit take when all the lamps are on?

Solution.—Resistance of 42 lamps in parallel $= \frac{150}{42}$ ohms.

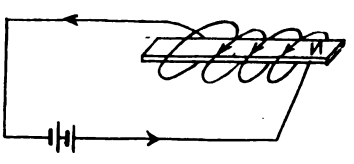
By Ohm's law $C = \frac{E}{R}$

$$= \frac{100 \text{ volts}}{\frac{150}{42} \text{ ohms}} = 100 \times \frac{42}{150} = 28 \text{ amperes.}$$

Answer.—28 amperes.

5. How can you convert a bar of iron into a magnet? If you have a small E.M.F., and no appreciable resistance in the rest of the circuit, would you use thin wires, or thick, for winding an electromagnet?

Answer 5.—Generally speaking, a bar of iron is magnetised when placed in a magnetic field, and since a very uniform field is produced in the interior of a spiral coil of wire through which a current circulates, a very convenient method of magnetising a bar of iron is to insert the iron into a hollow solenoid whilst the current is passing. This last condition is necessary, since the iron is a magnet only so long as the current is passing. The following sketch depicts the arrangement, and indicates the polarity of the bar when magnetised. The direction in which the current circulates decides which end is N.



In circuits with small E.M.F.'s, and an electromagnet forms one part of the circuit, then the resistance of the wire on the electromagnet should be of similar magnitude to that of the rest of the circuit; consequently, in the case under consideration thick wires should be used.

6. If electric bells are to be made to ring (by a magneto-ringer) through a line many miles in length, why must fine wire be used, both in the coils of the ringer and in the coils of the electromagnet in the bell?

Answer 6.—In telegraphic work the currents used are extremely small, as the resistance of the circuit is fairly high. Consequently, to get the required magnetising effect with the electromagnet, it is necessary to have a very large number of turns wound on the bobbins, and as fine wire will comfortably carry the small current, and at the same

Digitized by Google

time allow a large number of coils to be wound in a small space, fine wire is always used. In such cases as this, the battery is replaced by a small magneto dynamo, the armature of which is constructed so that the E.M.F. set up in it (when rotated) is fairly high—in fact, it must be sufficient to send the current through the high resistance of the circuit. This is accomplished by winding the armature coils with a large number of turns of fine wire. It should also be noted that when the resistance of one part of a circuit is high, as in the case of a line many miles in length, the resistance of the remaining part of the circuit should also be high.

7. Why is there a permanent steel magnet in the bells that are to be used with magneto-ringers?

Answer 7.—In magneto-ringers, a permanent magnet, in addition to an ordinary electromagnet, is employed, so as to secure unidirectionality of motion. If the armature of an electromagnet be soft iron, then attraction takes place whichever way the current circulates round the electromagnet, and if the current be rapidly and repeatedly reversed, the armature is still pulled. Now, in magneto-ringers, alternating currents are used, consequently the armature will remain stationary if made of soft iron, whilst if it be permanently magnetised it will oscillate to the right and left alternately; and as it is pivoted it throws the little hammer to and fro between two bells, the movements corresponding perfectly to the directions of the currents.

8. Describe shortly the construction of a glow lamp. Why does the filament become hotter than the platinum leading-in wires? Why does the globe of a bad lamp get very hot?

Answer 8.—A glow lamp is one in which light is produced by the passage of a current through carbon fixed in a vacuum. The parts of a glow lamp are:

(1) Carbon filament; (2) sealed and exhausted glass globe; (3) two leading-in wires of platinum; and (4) a base providing means of supporting the lamp and of making contact with the circuit.

The construction of such a lamp consists of three processes:

(1) *The Manufacture of the Filament.*—A satisfactory filament must be a bad conductor of electricity, and be practically infusible, and no substance supplies these qualities to the same degree as carbon. A thread or fibre of a suitable material, containing a large proportion of carbon, is prepared to the proper size and shape and then subjected to the action of a high temperature, whilst surrounded with a highly carbonaceous substance out of contact with the atmosphere. This process is known as carbonisation, and is continued until the filament is homogeneous in structure throughout.

(2) *Connecting to the Leading-in Wires.*—These are platinum; this metal being chosen because its melting point is high, and it may readily be fused in glass if necessary. The leading-in wires are connected to the filament by means of a carbon cement, or a deposit of carbon made over the junction, or by riveting. The leading-in wires are then fused in the glass globe, or permanently fixed in the base by means of a non-conducting cement. In the first method the platinum wires terminate in loops; in the other, the ends of the platinum wires are connected to pieces of brass to which connection is made with the external circuit. The filament thus fixed is then flashed. The filament is heated to a dull red by a current, and then surrounded by an atmosphere of hydrocarbon gas, which is decomposed, and a very dense deposit of carbon is made on the filament. This makes the filament more uniform.

(3) *The Production of the Vacuum.*—The filament is then fixed in a glass globe, which is exhausted of air by means of a vacuum pump, after which the globe is hermetically sealed, and the lamp is ready for use.

As is well known, the heating effect of a current is proportional to the square of the current passing and to the resistance of the conductor, and in all systems of electric lighting the principle adopted is to concentrate the resistance of a circuit at certain points where light is desired, and it is at such points where the heating effects are manifested; and since the resistance of the carbon filament is much greater than the resistance of the platinum leading-in wires, the former gets much hotter than the latter.

The quality of a lamp depends to a great extent on the degree of exhaustion of the lamp bulb. A bad lamp may be caused by only partial exhaustion, and in such cases the molecules of the air remaining in the globe will by *convection* remove a quantity of heat from the filament and give it to the glass, which in consequence becomes hot.

9. How many horse-power is required to drive a current of 100 amperes through a resistance of 7½ ohms?

Solution 9.—One horse-power is equivalent to 746 watts, and one watt is the power absorbed in a circuit when one ampere flows through it under a pressure of one volt;

$$\therefore W \text{ (watts)} = E \text{ (volts)} \times C \text{ (amperes)}, \text{ and } E = C \times R.$$

By Ohm's law,

$$\therefore W = C^2 \times R = 100 \times 100 \times 7{\cdot}5 = 75{,}000 \text{ watts};$$

$$\therefore \text{H.P.} = 75{,}000 \div 746 = 100 \text{ h.p (approximately)}.$$

10. State the principles on which the Cardew voltmeter is based.

Answer 10.—(1) *The heating effect of a current.* This voltmeter usually consists of a platinum-silver wire 13ft. long and 0·0025in. in diameter, and as the wire is very thin it very readily acquires the temperature corresponding to the particular current passing along the wire. The current passing is a measure of the E.M.F. between the terminal of the instrument. (2) *The expansion of a wire due to the rise of temperature produced by the current.* The elongation is proportional to the increase in the temperature, and the movement this elongation gives to a pointer is increased by a multiplying gear.

11. Name the principal parts of an arc lamp, and say what is the use of each part.

Answer 11.—(1) *Carbon pencils* of a very dense and homogeneous nature, made of coke carbon. When two carbon pencils are placed in contact, and a current of 10 to 15 amperes at a pressure of 40 to 50 volts is sent through them, the junction very soon becomes red hot, and Davy found that by separating the carbon about $\frac{1}{10}$in. a very brilliant white light was produced. When in use the carbons are gradually consumed. (2) *The arc.* The bright light just mentioned is produced by the spark which passes when the carbons are separated, and this volatilises a small quantity of carbon between the pencils. This carbon vapour has a very high resistance, but the E.M.F.'s employed are sufficient to send a current through it, with the result that the gap is raised to a high state of incandescence, forming an arch or bridge which is termed the voltaic arc. (3) *Feeding mechanism.* As the carbon pencils are gradually consumed some automatic arrangement is required to maintain a constant distance between the points, which is termed the feeding mechanism. In some lamps the mechanism consists of clockwork regulators, in others solenoids, brake-wheels, clutches, and motors are used. Whatever the arrangement may be, it should also *strike* the arc at the beginning.

12. Define "work" and "power." How many foot-pounds of work will be done in 20 minutes by a motor working at 4 h.p.?

Solution 12.—"Work" is done when force is overcome through a distance.

"Power" is the rate of doing work—*i.e.*, the work done in unit time.

$$4 \text{ h.p.} = 4 \times 33{,}000 \text{ foot-pounds per minute};$$

$$= 132{,}000 \quad \text{,,} \quad \text{,,} \quad \text{,,}$$

$\therefore$ in 20 minutes the amount of work done $= 20 \times 132{,}000$ foot-pounds $= 2{,}640{,}000$ foot-pounds.

REDUCING THE COST OF ELECTRIC LIGHT.*

BY NELSON W. PERRY.

It is so easy to prove on paper by means of apparently legitimate assumptions that the electric light can be made to sell at a considerable profit at a figure which is but a fraction of that usually charged that the public has been easily convinced that a bonanza attended the procurement of an electric lighting franchise in almost any municipality. The rude awakening to the investor when the annual statement has shown a balance on the wrong side of the ledger, in the face of the brilliant promises held out by lead-pencil prophecies, has too often come as a shock for which there seemed no other explanation so ready as that of wilful misrepresentation and dishonesty. The electric lighting industry has, therefore, suffered in reputation to such an extent as to make it difficult at the present day to float enterprises even of the most legitimate character. That dishonesty or incompetency has too often been charged where it did not really exist can readily be proved by figures from actual practice which show shortcomings in the performance of machinery that even central-station managers are only now beginning to realise.

A year ago the committee on data of the National Electric Light Association reported data of coal consumption per indicated horse-power in a large number of central stations, which attracted wide attention at the time, as indicating poor engineering practice. It was stated that with a consumption of 1·5lb. of coal per indicated horse-power, with a combined engine and dynamo efficiency of 81 per cent., a production of 402·84 watt-hours per pound of coal would result. This was equivalent to ·54 e.h.p. per pound of coal, or, in other words, an electrical horse-power could be generated for one hour on a consumption of a trifle over 1lb. of coal. The assumptions on which this statement was based seem entirely legitimate, since engines of a guaranteed efficiency of 90 per cent. and dynamos of an efficiency of 95 per cent. are readily obtained in the market, and it is not unusual to find a combined efficiency, under test conditions, of 85 per cent. These being facts, it was with considerable surprise to many that the results of actual practice were announced. The highest results given were 208 watt-hours per pound of coal. The next highest was 192, the lowest 25, and the average 91·7 watt-hours, or only 22·7 per cent. of that which was attainable by the best practice. In other words, the average central-station practice required 8lb. of coal to produce the same amount of electrical energy that machinery readily attainable was capable of producing on a consumption of 1·8lb.

This was a showing so unfavourable to electrical engineering practice as to cause considerable comment in the electrical journals and lead to some question as to the correctness of the figures. An average of data picked up haphazard, however, is not to be taken as a fair average of practice, and, since lower averages in efficiencies are to be expected in small stations where the units employed are small than in larger ones where apparatus of the highest refinements and possibilities are the rule, I discarded the reports from all stations consuming less than 10,000lb. of coal per 24 hours, and, averaging those above this, found a result of 127·7 watt-hours per pound of coal, or a consumption of about 5lb. of coal per electrical horse-power hour. This was a result which in ordinary steam practice would be poor even with small non-condensing engines, and yet undoubtedly most of the engines employed in the works whose results were considered were large compound engines, double or triple expansion and condensing.

At first blush these figures would seem to imply something radically wrong, and it was but natural to turn to foreign practice to see how it compared with ours. Such a reference shows that in the best English central stations the discrepancy between what ought to be and what is is even greater than in this country. Prof. Unwin is authority for the statement that probably the consumption (in England) has in no case been less than 3·3lb. of coal per indicated horse-power. This, with the assumed efficiency of 81 per cent. for engine and dynamo, would be equivalent to 4lb. of coal per electrical horse-power, and reports from several of the large London stations show a consumption of from 6lb. to 8lb. or more.

It was some satisfaction to find that American practice was at least no worse than that of our cousins across the water, who pride themselves upon greater refinements in engineering detail than we possess.

This same committee on data had been continued, and during the past year had been engaged in collecting further facts in regard to central-station economy, and their report, which was made at the Cleveland Convention last February, was awaited with considerable interest.

This report embraced data from 24 central stations, among which were several of the largest in the country—17 of which exceeded 10,000lb. of coal consumption per day. The average consumption of coal for all of those reporting was 127·7 watts per pound of coal, or 5·8lb. of coal per electrical horse-power hour. Taking, as before, only those stations consuming more than 10,000lb. of coal per day, we find the average to be 5·79lb. per electrical horse-power hour, which is a better showing for the average of all reporting, but not so good a showing for the average of those stations consuming in excess of 10,000lb. of coal per day. A very marked advance was shown, however, in this report in a single instance, which reported a total daily output of nearly 23,000,000 watts per day on a consumption of 87,358lb. of coal, which is equivalent to a consumption of a little more than 2·84lb. per electrical horse-power hour. This particular station, however, was the only one doing better than 4·11b. of coal per electrical horse-power hour, whereas in one case the consumption was as high as 24·8lb., and there were six reporting more than 7lb.

These figures are startling, and at once suggest the enquiry as to the cause of these low results. The answer cannot be more completely given than by quoting from some tests made by Prof. Kennedy at the Millbank-street station of the Westminster Electric Supply Corporation. Dividing the day into three portions, he determined the fuel consumption and the electrical horse-power developed during each period as follows:

TABLE OF COAL CONSUMPTION IN BOILERS WITH VARIABLE LOAD.

	11 a.m. to 6 p.m. 7 hours.	6 p.m. to midnight. 6 hours.	Midnight to 11 a.m. 11 hours.
Total i.h.p. hours	562	1,366	407
Total e.h.p. hours	400	979	280
Coal per i.h.p. hour, lbs.	6·88	3·26	6·26
Coal per e.h.p. hour, lbs.	9·67	4·55	9·80

This table shows very clearly the effect of light load upon coal consumption on engines of the same class, and although the best figures given—4·55lb. of coal per electrical horse-power hour, while the machinery was operating at its largest load—leave much to be desired, it is shown that even these are doubled during the hours of light load. They show unmistakably that at least one prolific cause of lack of economy in central-station practice is the extremely variable load to which the central lighting station must cater, and when we consider that even in New York City at least 2½ times as much machinery must be installed as could, if working continuously, produce the same gross output, we see another cause of expense in the way of interest and depreciation charges which in the lead-pencil estimates are apt not to be considered, or at least to be insufficiently provided for.

In fact, that these increased costs due to variable load are not well understood even by those presumed to be fairly well posted was well illustrated by some editorial comments in one of our leading engineering magazines upon some figures given by the author, which assumed the coal consumption per electrical horse-power hour under the conditions of continuous operation at 2·21lb., and that under ordinary conditions of practice at 4lb., the disparity being characterised as absurd. It seemed to me, therefore, probably not uninteresting to lay the facts before the public, who may not be expected to be so well posted as editors in general are supposed to be.

But while the item of fuel is an important one in the cost of electrical energy, it is by no means the only one which is seriously affected by the variable character of the

* From the *Engineering Magazine*, New York.

Digitized by Google

central station. I have already referred to its effect upon interest and depreciation charges, and these may in some cases become more important than the fuel charges. It is these that so often render the employment of water powers uneconomical, and which must militate so largely against the economical results from the great Niagara electrical power scheme. The most noteworthy electrical power transmission scheme that has thus far been tried was that of the Lauffen experiment in 1891, in which some 300 h.p. were transmitted electrically from the falls of the Neckar at Lauffen to the Frankfort Electrical Exposition grounds—a distance of 108 miles. Technically this was a great triumph, the efficiency of transmission having been about 75 per cent. Commercially, however, it was a failure, since the power cost, when delivered, five times as much as it could be produced for locally by means of steam. Thus we see how enticing water-power projects often fail commercially, independently of fuel charges or apparatus efficiency, but through exorbitant fixed charges incurred in rendering available what would otherwise prove a cheap source of energy.

There is also a popular misconception as to the relative costs in distribution of energy by different methods. Probably nine out of every ten to whom the question was propounded would answer unhesitatingly that energy for lighting purposes could be delivered more cheaply at a distance by electrical means than by means of gas transmission, and under some conditions this is true; but I find by calculation that if the distance involved were a mile, it would require considerably more metal to supply the electric lights by means of the direct current than would be required for pipes to convey a supply of gas for the same number of lights with the same efficiency of transmission.

The bane to the electric lighting industry is therefore the peculiar service which it is required to supply, reaching a very high maximum for a very few hours, and then descending to a very low mean, during which time the apparatus has but small earning capacity, and that portion which is not lying totally idle is producing energy at an uneconomical rate.

Could the central-station apparatus be kept in operation continuously at its most efficient output, the electric light could be sold to consumers at a considerable discount upon the price of gas, and still net the manufacturer a larger profit than the gas-man realises, and this without any change in apparatus or methods of distribution from those now in vogue.

The gas manufacturer, though he have exactly the same service to meet as the central-station manager, is not handicapped by the irregularity of this service, in that he can store up the product which he has to sell when the product is greater than the demand, and draw upon this store during the hours when the demand exceeds the supply. He need only supply sufficient apparatus to meet the average demand, and this, being kept in continual operation at its most efficient rate, earns to its fullest extent for every hour in the day. The central-station manager, on the other hand, has no method of storing up the product which he has to sell. If he employ storage of any kind at any stage of the manufacture, it introduces additional transformations of energy which not only are apt to be expensive in themselves, but also involve necessary losses in final output, which must be balanced against any economies which they may present.

It is natural, therefore, that relief should be sought rather in increasing the regularity of the demand than in these methods of storage; but here, too, difficulties present themselves which have not as yet been obviated. In the first place, if a day load should be acquired, it would tend to overlap the maximum lighting load, which in winter time comes on before six o'clock, and on dark days may be an hour or two earlier. The result would be that the double load, which at most would last but two hours, and which in the summer time would not exist at all, would have to be provided for by machinery which would be idle the rest of the day. It is clear, therefore, that this change would not better matters much.

(To be continued.)

MOUNTAIN-CLIMBING RAILWAYS.

BY ERNEST SCOTT.

(Continued from page 430.)

In 1879 Messrs. Thos. Cook and Sons decided to build a cable railway up the rugged side of Mount Vesuvius, over which for centuries stumbling and swearing *lazaroni* had dragged travellers to the summit. The power station is at the bottom of the track. It contains the 45-h.p. engine and boilers for working the cable, and also a dynamo for running the arc lights at night. The peculiarity of the track is the single-rail construction, which consists of wooden stringers laid longitudinally and carrying a single rail, upon which ride the central wheels of the car. There are, however, two other rails placed on either side of the base. These side rails are adapted to wheels whose axes project from the floor of the coaches and bear closely against the rails on either side of the sleeper, thus keeping the carriage firmly upright. Although the railway is only just over half a mile long it cost £16,000, a large proportion of which was expended in transporting materials for the railway. The maximum gradient is 63 per cent., and the journey takes 10 minutes. Each car carries 11 persons. The cable is of steel, $\frac{7}{8}$in. diameter, with hempen core. There are six strands of eight wires each. There are two cars, and as one descends the other is drawn up the mountain. Should the weight of the descending car overbalance that of the car going up, the brakes with which the winding-drums in the power-house are equipped regulate the speed of the machinery.

The railway at Barmen, in Rhenish Westphalia, was one of the first to be operated by electricity. It is just over a mile in length, the average gradient being 1 in 10 and the most severe 1 in 5. The railway constitutes a double line throughout, and the gauge is 3ft. 3$\frac{3}{8}$in. The cars accommodate 36 persons, and each car is equipped with two electric motors of 36 h.p. The motors actuate gearing which drives pinions gearing into the rack rail laid in the centre of the line. The current is collected from a copper conductor, as in the usual overhead trolley system, and after operating the motors returns by the rails to the generating station in the town. The generating pressure is 560 volts, and the overhead conductor is carried on transverse span wires, fixed to iron pillars in the town and to wooden masts in the open ground. The cars are provided with three brakes, and, including the termini, there are four stations.

The Brienz-Rothhorn reaches the highest point of any of the European railways. It summit level is 7,388ft. above the sea, being 610ft. higher than the Mount Pilatus Railway. The steam locomotives were built at the Swiss Locomotive Company's works, and cost £1,680 each. They weigh when empty 13 tons, and carry ·7 ton of coal or briquettes, 1·2 tons of water in tank, 1·2 tons in boiler, ·9 ton for cooling purposes, and oil, tools, and sundries make up a total weight of 17 tons. This load is distributed over three pairs of axles. The carriages were supplied by the Swiss Industrial Company, of Neufhausen, for £320 each.

The Wengern Alp Railway connects Lauterbrunnen and Grindelwald; it is single track, with passing loops at the station and at a point midway between Wengern and Wengern Alp. It is one of the longest lines that has yet been built, being 11·18 miles long altogether (10·68 miles of Wengern Alp railway). The return fares for the whole distance are 12s. for second class and 7s. 6d. for third class. The rack rail (Riggenbach system) is of improved form. The channel bars are specially rolled, with the upper portion of the web thickened where the rungs, 3$\frac{1}{2}\frac{5}{8}$in. pitch, forming the rack pass through. The top of each channel is bent slightly outwards, and the rack, being 3$\frac{1}{2}\frac{5}{8}$in. in clear width, gives ample room for the lateral play of the rack wheels, 2$\frac{3}{8}$in. broad, in passing round curves, etc. There are two rack wheels, not one, so that the stress on the teeth is reduced to half, and the unavoidable gap of rack rail at points and crossings is rendered workable, one or other of the rack wheels being always engaged. Each rack wheel has 18 teeth, and the distance apart of these wheels is 4ft. 5$\frac{3}{16}$in.

The Territet Glion-Naye wire-rope railway is worked on the water-ballast system. There are two inclines. The lower one from the Lake of Geneva to the village of Glion, 1,000ft. above, was laid down in 1883; the upper one, forming the extension from Glion to Naye, being put down just 10 years later. The line is single track, with a turn-out about the centre. There is a rack midway between the rails, but it is for braking purposes only. The cable is 1$\frac{1}{4}$in. diameter and weighs 8·47lb. per yard. The car when empty weighs 8·66 tons, with tank filled, but without passengers it weighs 13·68 tons; as against 11·81 tons for the laden car with its tank empty.

The Mount Salève rack railway was one of the first to be worked with electricity. The track is laid on the well-known Abt system, 3ft. 3$\frac{3}{8}$in. gauge; but, instead of overhead wires, a conductor rail of the same section as the ordinary rail is used, and, as in several of the American lines, it is placed about 18in. outside the left-hand rail. It is inverted, and its base used as contact surface. At distances of 6ft., or at every alternate sleeper, the inverted head of the conductor is held by an iron clamp and cap, which rests on a double porcelain bell insulator, 3in. diameter, this being in turn supported by a bent iron bracket fastened to the surface of the transverse sleepers. There is a complete metallic return beside the rails. The generating station is situated at Arthaz, on the River Arve, which is really a mountain torrent descending from Mont Blanc and discharging into the Rhone just below the lower end of the Lake of Geneva. The financial results show that there is a great saving in using this water power. The dynamos are among the largest yet made, and are of the multipolar Thury type with 12 poles. They weigh 19 tons each, and are coupled direct

Digitized by Google

to the vertical turbine shaft, which is 7⅞in. diameter. The outside diameter of the dynamo is 10ft. 6in., and the diameter of the armature 6ft. 9in. At a speed of 45 revolutions the effective output is 600 volts 275 amperes, or 165 kilowatts, equal to 220 e.h.p The commutator is 5ft. 9in. diameter, and current is taken off by 36 carbon brushes in 12 sets, which are fastened to ebonite holders and pressed by springs against the collector surface. There is practically no sparking, owing to the substitution of carbon blocks for the ordinary copper brush. The two motors with which each car is fitted are four-pole series-wound, and in series with each other. The armature is 16in. diameter by 32in. long. They develop 30 h.p. at 600 revolutions per minute. The rack pinions are driven through double gearing, the reduction being 12 to 1. The speed regulator is composed of a handwheel, which, by worm gearing, acts on a regulating switch having forward and reverse motion, two sets of contacts each connecting by as many conductors with the resistance coils made of iron wire, and carried under one of the platforms of the car. The total costs amounted to £92,000. The losses are 48 per cent., of which 10 per cent. are in the generators, 12 per cent. in the transmission and conducting rails, and 26 per cent in the motors and gear. Unlike most others, this line is intended to work all the year round when not prevented by snow or by the freezing of the turbines. In summer there are 30 up and down trips per day, and in winter 15. The maximum traffic would be 1,100 persons a day, and the fare from Geneva and back is 4s. 6d.

The most conspicuous recent advance in mountain climbing by mechanical means has been the building of cable railways up the Burgenstock, Monte Salvatore, and Stanserhorn. In each case the winding-drums are worked by electric motors. The Stanserhorn line was only opened in 1894, and all three lines have been financed and built by a large Swiss firm of contractors, Messrs. Bucher and Durrer. As far as is possible, the profile of these cable lines are a concave parabolic curve.

The Burgenstock line is single throughout, with an automatic turn-out midway up the incline. This crossing is Mr. Abt's design, and is exceedingly simple. In order to effect the crossing of the up and down cars the outer wheels of each car have a double flange, and as they always run on the outer rail do not come in contact with the rack. The car wheels on the other side are flat, and being without flange and extra wide, they cross easily and smoothly over the rack and joints of the rails. The cable is Lang's patent, of crucible cast steel with hemp core, its diameter being 1 18in. and its weight 6·4lb. per yard. The steel cable is divided into 114 wires arranged in six strands, and the breaking strength is 46 tons, this giving a factor of safety of about 9 The life of the cable, making a mileage of 2,000 miles per annum, may be taken at about 10 years. The cable is worked through gearing having a reduction of 140 to 1 by two Thury motors, 25 h.p. each. Current is derived from a hydro-electric power station near Buochs, 2½ miles distant, the transmission being on the three-wire system at 1,600 volts This station also supplies the Stans road and the Stanserhorn railways with electric power.

The Monte Salvatore Railway is almost exactly like the Burgenstock, the principal points of difference being that the line is built in two sections and is single track throughout ; a midway station (where passengers change) taking the place of the automatic turn-out on the Burgenstock line. The total weight of the permanent way is 172lb. per yard as against 192lb. per yard on the Burgenstock. The cable is composed of 90 wires arranged in six strands ; its diameter is 1·26in. and weight 6·8lb. per yard, and its tensile strength 54 tons giving a factor of safety of 10. The hydro-electric generating station is five miles distant, current being transmitted at 2,000 volts The return fare is 3s. 3d.

The Stanserhorn line being built without a rack, the total weight per yard comes out lower than the other lines, being only 134lb. per yard. The saving in material and labour is about £1. 4s. per yard. The speed of the car is regulated at the motor station, automatic and electric signals acquainting the driver of the position of the cars on the line. As mentioned above, current for the motors is generated at the central station at Buochs, and is supplied at the fixed charge of £4 per horse-power per annum. The power is transmitted at 1,600 volts through six conductors (two to each station) ·35in. diameter, the mean loss in volts being 12 per cent. The Stanserhorn Cable Railway is built in three sections, each worked with a separate cable and a midway automatic turn-out. The advantages of this are that the carrying capacity of the line is very much increased and the cable is not so unwieldy. The feature of this railway is that, instead of the usual rack, a special safety brake, acting on the rails (by clutching the rail-head), is used. This elimination of the rack gives a considerable saving in first cost of permanent way, more space for the cable and rollers, and greater simplicity in working. The rail clutch-brake, of which there are three to each car, acts both automatically and under control of the driver. Each consists of a pair of jaws, like a pair of pincers, which normally travel along the triangular-shaped rail-head with a clearance of about ¼in. When the car speed unduly increases, they close on the rail and arrest the car by friction pressure. Again, in the event of the cable snapping, two counterpoise weights of 110lb. each, which are usually held up by the tension of the cable, fall and act by levers on the gearing which operates the jaw brake. The total mileage of the cables used on these railways will probably be about 20,000 miles, and this with the present rate of traffic on the Stanserhorn Railway—viz., 10 trains per day for six months—gives a life of seven years. These three electrically-worked lines show a saving of 50 per cent. in cost of construction and working expenses when compared with the Lauterbrunnen and Pilatus Railways.

(To be continued.)

ABERDEEN CORPORATION ELECTRICITY WORKS.

The following are the particulars of the electric light accounts of the Corporation for the period from February 28, 1894, to December 31, 1894 :

Revenue and Expenditure Account.	£	s.	d.
Sale of current, per meter, at 7d. per Board of Trade unit	1,679	11	1
Public lighting	113	16	1
Rental of meters	56	13	2
	£1,850	0	4
Cr.	£	s.	d.
Fuel	189	1	1
Oil, waste, water, and engine-room stores	60	10	7
Wages at generating station	146	12	4
Repairs on buildings	1	11	7
Repairs on plant	2	12	7
Main and service repairs	13	13	10
Attending and maintaining public lamps to May 16, 1894	15	7	3
Feu duty and taxes	102	19	8
Management	50	0	0
Salaries of engineers	252	6	0
General establishment charges	21	19	5
Stationery and printing	9	16	3
Insurance	12	9	6
Inspector's wages	0	9	5
Balance carried to net revenue account	970	10	10
	£1,850	0	4

Net Revenue Account.	£	s.	d.
Balance brought from revenue and expenditure account	970	10	10
Balance chargeable against the gas department—carried to general balance account	217	15	6
	£1,188	6	4

Cr.	£	s.	d.
Interest on mortgage and other loans	523	5	6
Depreciation for 10 months on amount expended on capital account at February 28, 1894 :			
Buildings, £3,375 at 1 per cent. (£28 2 6)			
Machinery, £4,289 at 5 per cent. (178 14 2)			
Accumulators, £571 at 5 per cent. (23 15 10)			
Mains and services, £8,119 at 1½ per cent. (101 9 2)			
Electrical instruments, £1,150 at 2½ per cent. (23 19 2)			
Meters, 296 at 5 per cent. (12 6 8)	368	7	6
Sinking fund on £17,800, at 2 per cent., for 10 months	296	13	4
	£1,188	6	4

General Balance Account. Assets.	£	s.	d.
Capital account—amount expended for works	23,189	7	6
Sundry debtors for current supplied to December 31, 1894, outstanding	1,341	8	9

Amount of deposits in security for current	20	0	0
Sinking fund	296	13	4
	£25,185	16	2

THE ELECTRIC LIGHTING OF EDINBURGH.

The inauguration of the public installation of electric light in Edinburgh took place on Thursday last week. The Edinburgh Corporation electric light order was passed in 1891, but it was not until April 21, 1893, that the Town Council, by resolution, resolved to keep the electric lighting in its own hands. An electric light sub-committee was elected with Mr. A. D. Mackenzie as convener ; Prof. Kennedy was appointed consulting engineer to the Corporation, and Mr. Monkhouse resident engineer. The first installation resolved on was one of considerable magnitude — estimated, as it was, to cost about £85,000, independently of site and station buildings—and the carrying of it into effect has represented during the past 18 months an immense amount of anxious and arduous work to all concerned. The scheme has been

Digitized by Google

enlarged considerably since its inception, and may probably be set down to cost something like £120,000.

The central electric light station is situated in Torphichen-street and Dewar-place, in close proximity to the Caledonian Railway, with which it will be connected by a siding for the direct delivery of coal and other material. Designed, says the *Scotsman*, by Mr. Cooper, burgh engineer, in the Italian Renaissance style, it is a solidly built structure of red freestone, with certain ornamental features, chiefly associated with its fenestration. The engine-house, which is 104ft. by 90ft., is divided into two large naves, separated from each other by a series of cast-iron columns. The boiler-house is a long, oblong building alongside the engine-house, 150ft. by 46ft. One half of the engine-house is set apart for the low-tension distribution dynamos, and it is these which are now being utilised. In the other half will be placed the engines and dynamos for the high-tension distribution, but these are not yet in position. The engines and dynamos are in two parallel rows on each side of a broad gangway along the centre of the engine-room, and together represent nearly one-half of the low-tension plant of 1,500 i.h.p. The engines are of the horizontal compound type, and run at a speed of from 350 to 400 revolutions per minute. They drive the dynamo direct. There are eight dynamos in all. Two are balancing machines of 100 h.p. each, which will be used for equalising the load on the two sides of the three-wire system; two are charging machines of 100 h.p. each for charging batteries and other purposes; two are of 250 h.p.; and the two largest are of 360 h.p.

The space beyond the engine platform is left for extension. It is at present 3ft. lower than the platform, but that is merely for convenience of working. In the high-tension side there will be fitted up within the next few weeks two engines of 150 h.p., each driving an alternator. They will be used at first for long-distance arc lighting in such streets as the Canongate and Clerk-street, and later when required for providing current to other districts considerably removed from the central station.

At the west end of the engine-house, at an elevation of 4ft. above the general floor, there is the switchboard platform. In each of the two sections of the engine-house are overhead travelling cranes, which have been of great use in lifting machinery and other plant. The walls are lined up to a height of 12ft. with white glazed bricks, and at that height is a narrow cornice of green glazed tiles. The pipe for the steam supply is hung from brackets round the walls in the form of a ring with two openings into the boiler-room. It is divided into a series of sections with stop-valves, so that with the two boiler-house openings it virtually gives a duplicate steam supply in case of accidents. The main exhaust-pipe for the waste steam is carried in a tunnel under the flooring, and discharges itself into the main chimney stalk, but before doing so it is utilised to heat the feed-water before it goes into the boilers. The main chimney stack is 165ft. in height from the ground line, and is of rather ornamental design. It is octagonal in plan, and has pilasters and panels, with moulded cornice and cap.

The boiler-house, the east end of which is not yet finished, contains six large double-furnace boilers, of marine type, fitted with Sinclair's mechanical stoking arrangement. The boilers, which were made by Mr. George Sinclair, of Leith, are to work up to a pressure of 160lb. to the square inch, and they have been tested and have proved themselves thoroughly sound and tight up to a pressure of 320lb. The system of superheating the steam after it leaves the boilers by means of the waste gases from the furnaces has been adopted, and is likely to give good results both from an engineering and an economical point of view. In the centre of the boiler-house is Berryman's feed-heating apparatus. On the other side there are feed-pumps driven by electricity, to take the place of the ordinary donkey pumps for feeding the boilers with water. This, it is believed, is the first time that such pumps have been put up in a British station. There is also an electrical motor for driving the mechanical stokers. Over the boiler-house will be a large second floor, carried on iron beams, which will be used as a coal-store, from which there will be "tips" into the mechanical stokers. Over one part of the engine-house is a battery-room, where are placed large nests of secondary batteries, which will be used for giving off current during the day, either for lighting or motive power, when the machinery is not running. There are batteries here sufficient to keep going 1,200 lamps of 8 c.p. for five hours. These batteries will allow the station to be shut down in summer at 4 a.m. or earlier, and kept shut down until four or five the next afternoon, or even later; and they are regarded as of great importance in the economy as well as in the convenience of management of the station. The regulation of these batteries and the placing of them in circuit is carried out by an ingenious arrangement devised by Mr. Jenkin (a son of the late Prof. Fleeming Jenkin), one of Prof. Kennedy's assistants. On the same level are rooms for the testing and storing of electrical meters—of which two kinds are to be used—the Kelvin and the Ferranti—and rooms for general stores, with a lift to St. Cuthbert's-lane. The main staircase is placed in an annexe to the west of the chief building in Dewar-place, and in the same building are the offices of the staff. Opening from one of the landings of the staircase is a spectators' gallery, built out of the wall at a corner of the high-tension side of the engine-house, from which all the machinery may be overlooked.

The distributing system adopted is a low-tension continuous-current three-wire one, with batteries for all the central and western part of the city—in fact, for all the part in which distributing mains are laid. This low-tension distribution will be extended as time goes on to all the closely-populated parts of the city. Meantime, outlying districts and residential suburbs, where houses stand far apart in gardens and isolated from each other—where the cost of mains for consumer is a maximum, and where the receipts per lamp per annum are a minimum—are to be supplied by alternating current, leaving the station at high pressure (2,000 volts), and transformed down by isolated transformers to 100 volts or 115 volts for the consumer.

Princes-street is lighted with a series of arc lamps hung on ornamental brackets 23ft. in height, and placed about 50 yards apart on the north side of the street. Each of these is of 15-ampere power, which popularly is set down as representing 3,000 candles, so that when the light is turned on Princes-street will be one of the best lighted streets in Europe. The total number of arc lamps which will be used for street-lighting purposes is 175. The lamps are of the Crompton-Pochin type.

The whole scheming of the work, the choice of system, the arrangement of station, the sizes and arrangement of plant, the plan of mains, etc., the whole preparation of the detailed specifications, and the general supervision of the execution of the scheme, have been performed by Prof. Kennedy, acting as consulting engineer to the Corporation.

The principal contractors were: Buildings (amount £18,297), W. Turner and Sons, Morrison-street, Edinburgh; boilers and superheaters, George Sinclair, Leith; machinery generally, Siemens Bros., Woolwich; with sub-contractors (*a*) for engines, Willans and Robinson, Thames Ditton; (*b*) for pipes, etc., Alley and Maclellan, Glasgow; switchboard and instruments, Siemens Bros.; batteries, the Crompton-Howell Company; cables, Henley's Telegraph Works, Siemens Bros., and the India Rubber Company, Silvertown; stoneware casings for road-work, Doulton; arc lamps, Crompton and Co.; arc lamp-posts, Mackenzie Bros., Edinburgh; iron-work generally, Shaw and Co., Glasgow, and R. Maclaren and Co., Glasgow; alternators, Ferranti and Co.; with engines by Willans and Robinson; rectifiers for the arc lamps on the alternating-current circuit, Ferranti and Co.; high-tension switchboard, Ferranti and Co.

COMPANIES' REPORTS.

METROPOLITAN ELECTRIC SUPPLY COMPANY, LIMITED.

Directors: Sir John Pender, G.C.M.G., M.P., chairman; Admiral of the Fleet Lord John Hay, G.C.B.; Admiral Sir George H. Richards, K.C.B., F.R.S.; Sir Eyre M. Shaw, K.C.B.; J. C. Parkinson, Esq.; J. Denison Pender, Esq.; John B. Verity, Esq. Secretary: E. Cunliffe Owen, Esq., C.M.G. Chief engineer: Frank Bailey, Esq., A.M.I.C.E. Acting engineer: A. H. Walton, Esq., A.M.I.C.E. Consulting engineers: Lord Kelvin, D.C.L., Pres.R.S.; Dr. John Hopkinson, F.R.S.

Report of directors and abstract of accounts to be presented to the shareholders at the eighth ordinary general meeting of the Company to be held at Winchester House, Old Broad-street, on Wednesday, April 24, at 12 noon.

The capital expenditure, which at the end of 1893 amounted to £585,932. 8s. 9d., now shows a total of £628,931. 7s. 1d., being an increase during the year of £42,998. 18s. 4d. This increase is mainly accounted for by the growth of the Company's business, necessitating an increase of plant as well as the continual extension of mains, and the additional provision of transformers, meters, and other appliances. Litigation has taken place in connection with the works at South-street, Manchester-square, arising from complaints that vibration was caused to the neighbouring houses. The measures which the directors have taken to remove all cause for such complaints have now been successfully carried out. Considerable difficulty was experienced in maintaining the public supply while the alterations were in progress, and a material increase in working expenditure throughout the Company's entire system was thereby incurred. The gross revenue for the year amounted to £85,345. 18s. 7d., against £69,195. 4s. 4d. in 1893, being an increase of £16,150. 14s. 3d., as compared with the increase of £14,623. 5s. 4d. in 1893. It will be seen that the growth of the income has steadily kept pace with that of the lamp connection, notwithstanding that the directors have found it necessary to introduce a sliding scale of charges in favour of large consumers of current. The balance to the credit of the revenue account before providing for depreciation is £29,998. 2s 4d. The directors have set aside £8,000 as an addition to the depreciation fund, carrying to the credit of the net revenue account the sum of £21,998. 2s. 4d., which, with the balance brought forward from the last account and other receipts, makes a total of £23,761. 12s. 4d. After deducting debenture interest and other charges, there remains a balance of £16,909. 2s., of which the directors have appropriated a

Digitized by Google

further sum of £1,000 in reduction of the preliminary expenses account, which is now diminished to £2,052. 10s. 4d. The directors recommend that a dividend of 6s. per share on the ordinary share capital be now paid, which will absorb a sum of £14,970, and leave a balance of £939. 2s. to be carried forward to the next account. In view of the increased capital expenditure consequent on the extension of the Company's business, and to take advantage of the favourable condition of the money market, the directors decided to replace the 5 per cent. debenture bonds by the creation of £250,000 4½ per cent. first mortgage debenture stock, of which a portion, amounting to £150,000, was issued in July. With the funds thus obtained, the whole of the £100,000 5 per cent. bonds have been redeemed, and a further sum of £50,000 provided for current capital expenditure. The net premium derived from the issue has been carried to the credit of the depreciation fund. The number of 8-c.p. lamps supplied by the Company increased during the year 1893 from 166 000 to 209,000. The present number of lamps connected is 224,000, and the applications show no signs of decrease. A report from the Company's chief engineer is appended, showing that the satisfactory condition of the stations, machinery, and plant has been maintained. In accordance with the articles of association the following directors—viz., Admiral Sir George H Richards, K.C.B., F.R.S., Sir Eyre Massey Shaw, K.C.B., and John B. Verity, Esq.—retire from the Board, and, being eligible, offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths, and Co., also retire, and offer themselves for re-election.

REVENUE ACCOUNT FOR YEAR ENDING DEC. 31, 1894.

COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING COMPANY, LIMITED.

Directors: Right Hon. D. R. Plunket, Q.C., M.P., chairman; J. B. Braithwaite, jun., deputy-chairman; W. C. Braithwaite; Anthony N. Denny; Frederick W. Reynolds; Aymor H. Sanderson; Francis E. Savory; R. Percy Sellon; B. H. Van Tromp. Engineer and manager: A. J. Lawson, M.I.E.E.

Directors' report and balance-sheet to December 31, 1894, to be presented to the annual general meeting of the Company, to be held at the City Terminus Hotel, Cannon-street, E.C., on Monday, April 22, 1895, at 2 p.m.

Since the balance-sheet was made up the first issue of 10,000 preference shares of £10 each has taken place, and the amount offered was very largely over-subscribed. An application for the quotation of both the ordinary and preference shares in the Stock Exchange official list has been made. The accounts show a considerable capital expenditure within this, the first year of the Company's operations upon works now in progress. On the profit and loss account for the year, after payment of usual general charges and writing off preliminary expenses on account of the Canterbury Electricity Supply Company's undertaking, which amounted to £308. 12s. 2d., a credit balance of £332. 5s. 10d. remains. The laying of pipes for mains and construction of drawing-in boxes within the St. Luke's and Clerkenwell districts is approaching completion. Cables are being delivered and laid, and it is hoped that by the end of September next both the St. Luke's and Clerkenwell districts will be supplied with current from the generating station which is now being built at City-road basin of the Regent's Canal. Street works in the Wandsworth district have been unavoidably delayed, but upon settlement of the regulations by the Board of Trade, main-laying can be forthwith commenced. The plans of the generating station buildings are nearly completed. An application for a provisional order for the district of St. Olave, Southwark, has been made to the Board of Trade, and the consent of the local authority to that application has been obtained. This district adjoins that of St. George-the-Martyr, Southwark (for which the Company now holds a provisional order), and both areas can be supplied from one generating station. The Bournemouth station, in which the Company holds the controlling interest, has within the past year made material progress. The number of consumers has considerably increased, so that at the end of the year there were connected an equivalent of 19,000 8-c.p. lamps, or 4,500 in excess of the number supplied at the end of 1893. To meet with the steadily increasing demand a further capital expenditure has been necessary for extension of station buildings and for additional plant and mains. Upon the completion of the work in progress the Bournemouth station will have a capacity of 27,000 8-c.p. lamps con-

Digitized by Google

nected, with a total capital expenditure not exceeding £75,000. The Company is also the principal shareholder in the Dover Electricity Supply Company, of which Sir William Crundall, mayor of Dover, is chairman. The station of that company is now completed, part of the plant has been erected, current is being supplied, and the remainder of the machinery under the original contract will shortly be delivered. Contracts for public and private lighting are already entered into for the equipment of 2,200 8-c.p. lamps, and other contracts are in course of negotiation. A provisional order has been applied for in the name of the Windermere and District Electricity Supply Company for the supply of electricity for lighting, power, and other purposes in the towns of Ulverston, Grange, Cartmel, Bowness, Windermere, Rydal, and Grassmere, and in all these cases the consents of the local authorities to the application of the Company have been obtained. A controlling interest in the company holding the provisional order for Richmond (Surrey), with a central station well equipped and in active work, has recently been acquired on reasonable terms. The retiring directors are the Right Hon. D. R. Plunket and Mr. F. W. Reynolds, who are eligible for re-election. The auditor, Mr. R. H. Marsh, also retires, and is eligible for re election.

OXFORD ELECTRIC COMPANY, LIMITED.

Directors: Sir Henry C. Mance, C.I.E., M.I.C.E. (chairman); Jas. W. Barclay; Robert Buckell, J.P.; L. A. Selby-Bigge, M.A.; John Irving Courtenay, M.A. Engineer: J. Hardie McLean, M.I.E.E. Secretary: Hy. Eeles.

Report of the directors and abstract of accounts for the year ending December 31, 1894.

The revenue account shows a gross profit of £1,701. 17s. 2d. After providing for the full interest of 5 per cent. on the debenture issue and other interest, there remains £456 2s. 10d., which, added to the amount brought forward from the previous year, £68. 8s. 5d., leaves an available balance of £524 11s. 3d. The directors recommend that a dividend of 1 per cent., free of income tax, be paid upon the ordinary shares, which will absorb £329. 6s. 7d., leaving £195 4s. 8d. to be carried forward to the next account. The running of the plant during the year has given entire satisfaction. The supply of current to the public has been uninterrupted day or night from the time the Company commenced operations. Since the last report 4,194 8-c.p. lamps (or their equivalent) have been added to the system. On December 31 the number of lamps connected equalled 11,206 8-c.p. lamps. Thirteen colleges are now connected to the mains, and the directors have every reason to hope that the increase in the number of lights during 1895 will be equally satisfactory. During 1894 extensions have been made to Beaumont and Worcester streets, Magdalen Schools, St. Aldate's, St. Giles's, and the north of Oxford (Banbury-road, Norham-gardens, Norham-road, Bardwell-road, North-parade-avenue). These extensions involve considerable capital expenditure, for which provision has been made. The results so far have been sufficiently encouraging to justify the expectation that there will be a substantial addition to the number of consumers in the north of Oxford during the present year. The plant has been maintained in efficient order, and the expenditure of coal per unit of current generated reduced to ·44 of a penny. The directors who retire by rotation are Sir Henry Mance and Mr. James W. Barclay, who offer themselves for re-election. Mr. W. S. Carver, the auditor, retires, but offers himself for re-election.

BRIGHTON AND ROTTINGDEAN SEASHORE ELECTRIC TRAMROAD COMPANY.

Directors: Edward Overall Bleackley (chairman), 14, Chichester-terrace, Brighton; John Jackson Clark, Goldstone House, Hove; Richard John Pope, Beresford Manor, Plumpton; Magnus Volk, 36, Eaton-place, Brighton.

Report of directors, with abstract of accounts, for period ending December 31, 1894.

The directors regret that they are not able to announce the completion of the line, but owing to the delays that took place in making the necessary arrangements with the Board of Trade and the Corporation of Brighton the work of constructing the permanent way was not commenced in earnest till the end of July. Thus the best part of the year was lost, and the weather all through the autumn was so stormy, and the winter so intensely cold, that not only was progress necessarily slow, but the cost of the work was thereby considerably increased. During the last few weeks, however, rapid progress has been made, and if the weather continues favourable the directors expect to see the permanent way completed in the early part of the summer. Notwithstanding the heavy gales and the exceptionally rough seas to which it has been subjected, it is highly satisfactory to note that not the slightest damage has been done to any portion of the permanent way. The stability of the work may therefore be considered as perfectly assured, and the directors confidently anticipate that the undertaking will prove a very great success. As the railway may be fairly expected to greatly increase the popularity of Rottingdean as a summer resort, it has been considered desirable to erect the landing-jetty there on an enlarged scale, so as form a commodious pier, from which a good revenue may be reasonably anticipated. Arrangements have been made by which the Company will pay half the cost of constructing a sea-wall and promenade approach to this pier, which will improve the property of the Company and the appearance of the frontage at Rottingdean. It was originally intended to place the Brighton station on the beach on the west side of the Paston-place groyne; but it has been considered desirable to erect a jetty immediately to the east of the groyne, with a station thereon, so that passengers may reach the car with greater comfort. These works, as well as the Rottingdean pier, are practically completed. As the Corporation of Brighton raised objections to the generating machinery being placed in the Company's station, it became necessary to excavate an arch for this purpose in the concrete sea-wall close by, the site being granted by the Corporation at a nominal rent for 21 years, so as to recoup the Company the cost of constructing the arch. The original estimates did not provide for any of the additional works above mentioned. Moreover, the cost of laying the permanent way has been increased through being carried out in such unfortunate weather, and there have been other expenses, of which, in a work of so unique a character, it was difficult to form an accurate estimate. It will therefore be necessary to issue the balance of the share capital, amounting to £5,680, in order to complete and thoroughly equip the line. Of this sum the directors will subscribe £2,000, and the balance is offered in the first place to the existing shareholders Any portion not taken by them will be offered to the public. One director, Mr. Magnus Volk, retires by rotation, and, being eligible, offers himself for re-election. The retiring auditor is Mr. James T. Haslam, who offers himself for re-election.

INDO-EUROPEAN TELEGRAPH COMPANY, LIMITED.

The report of this Company for 1894 states that the revenue from all sources amounted to £119,118, as compared with £122,860 for 1893, showing a decrease of £3,742. The expenses were—on commercial and general account, £32,841; on maintenance account, £31,998; total, £64,839, as against £64,960, a decrease of £121. Deducting the expenses, taking credit for £6,452 brought over, and debiting income tax, there remains £58,289. From this amount £10,000 has been placed to reserve, and that sum, together with £10,625 for interim dividend, have to be deducted, leaving a balance of £37,664 The directors now propose the declaration of a dividend for the last six months of 17s. 6d. per share, making, with the dividend already paid, 6 per cent. and a bonus of 20s. per share, both free of income tax, in all 10 per cent. for the year, carrying forward £5,789. It has been determined by the governments and companies interested, under slight modifications of the guarantee arrangements, owing to which the existing low tariff with Australasia was originally established, to continue its application for a further period of five years.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Llandrindod Wells.—The Urban District Council invite offers for the provisional electric lighting order for which they are applying.

South Shields.—Tenders are invited for the supply and erection of a 10-ton hand-power overhead travelling crane at the Corporation electricity works. We have already given particulars. Tenders to be delivered by 22nd inst.

Manchester.—The Lancashire and Yorkshire Railway Company require by the 30th April tenders for the supply of an oil-engine engine packing, signal and telegraph fittings, signal, telegraph and electric light wires, wire, etc.

Londonderry.—The Corporation invite tenders for the supply of carbons for one year from June 1, 1895. Schedules of quantities and further particulars may be obtained on application to Mr. John Christie, electrical engineer, Strand, Londonderry. Tenders, accompanied with samples, marked "Tender for Carbons," to be lodged with Mr. R. Chambers, town clerk, not later than May 1.

Huddersfield.—The Electric Lighting Committee of the Town Council invite tenders for 2in. and 3in. cast-iron spigot and socket pipes. Specifications and form of tender may be obtained on application from Mr. A B. Mountain, borough electrical engineer, St. Andrew's-road, Huddersfield. Tenders are to be delivered by the 26th inst. at the borough electrical engineer's office, marked "Tender for Cast-Iron Conduits."

Rangoon.—Tenders will be received by the president of the Rangoon Municipal Committee, not later than November 4, for the lighting of Rangoon by electricity. Tenders should be accompanied by detailed plans, specifications, and estimates, and must state the terms on which the installation proposed will be undertaken. All information regarding the existing system of lighting and the cost, etc., with plan of the town, can be obtained on application to Messrs. Ogilvy, Gillanders, and Co., Sun-court, 67, Cornhill, London, E.C., accompanied by a remittance of £1. 1s. Tenders are to be sent in sealed covers and endorsed "Tender for Electric Lighting, Rangoon." Mr. J. Short, Rangoon, is the secretary of the committee.

Brighton.—The Town Council invite tenders for the extension of the Corporation electricity generating station, North-road, comprising engine-room, boiler-house, coal stores, chimney shaft, and other works in connection therewith, for the Town Council. Drawings may be seen at the office of the borough engineer and surveyor, Mr. Francis J. C. May, M I.C.E., Town Hall, Brighton, where specification, bills of quantities, and forms of tender can be obtained after 10th inst. upon the payment of £5. 5s., which sum

Digitized by Google

will be returned on the receipt of a *bonâ fide* tender. Sealed tenders, addressed to Mr. Francis J. Tillstone, town clerk, Town Hall, Brighton, and endorsed "Tender for Extension of Corporation Electricity Station," must be left at the town clerk's office before 10 a.m. on 25th inst.

Birkenhead.—The Corporation invite tenders for the erection and completion of a brick chimney 124ft. high above concrete bed, and for the construction of the necessary foundations thereof, in connection with the electric light station. Plans, specifications, and particulars, with form of contract, can be seen, and (upon deposit of the sum of £1. 1s., which will be repaid upon receipt by the Corporation of a *bonâ fide* tender) bills of quantities, with form of tender, can be obtained, on application at the town clerk's office, Town Hall, Birkenhead, or at the office of Mr. James N. Shoolbred, M.I.C.E., Albany-buildings, 47, Victoria-street, London, S.W. Tenders, which must be on the prescribed form, sealed and endorsed "Tender for Erection of Chimney," must reach Mr. Alfred Gill, town clerk, Town Hall, Birkenhead, by 12 noon on 22nd inst.

RESULTS OF TENDERS.

Edmonton.—The District Council have accepted the tender of the Consolidated Telephone Construction and Maintenance Company, Limited, for street fire-alarms.

Hull.—The Electric Lighting Committee of the Town Council have accepted the tenders of Messrs. Willans and Robinson for an engine at £1,295 and Messrs. J. H. Holmes and Co. for a dynamo at £700.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—The receipts for the past week were £2,684.

The New Public Record Office.—This building in Chancery-lane is to be lighted throughout by electricity.

Glasgow.—The Theatre Royal is to be rebuilt at a cost of about £20,000, and the electric light is to be installed throughout. Mr. C. J. Phipps is the architect.

Basingstoke.—The Public Lighting Committee of the Urban District Council have decided that it is inexpedient at present to adopt a scheme of electric lighting.

Metropolitan Electric Supply Company, Limited.—Notice is given that the transfer registers of the Company will be closed from 18th to 25th inst., both days inclusive.

Argentina.—From Buenos Ayres, under the date of March 25, it is announced that the La Plata Telegraph Department is calling for tenders for supply of telegraphic materials.

Coventry.—The Town Council have ordered the corporate seal to be affixed to mortgages of the general district fund for raising £2,000 at 3½ per cent., for electric lighting, etc.

West India and Panama Telegraph Company.—For the half-month ended April 15 the receipts show a decrease of £214 as compared with the corresponding period of 1894.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 14th inst. amounted to £1,243, as compared with £655 in the corresponding week of last year.

British and Foreign Patent Syndicate, Limited.—This Company has been registered with a capital of £10,000 to carry on business as patent agents, to render assistance to inventors, etc.

Pure Carbon Company, Limited.—This Company has been registered, with a capital of £12,000, to adopt an agreement for the acquisition of certain patents, and to develop and turn to account the same.

Oriental Telephone and Electric Company.—A dividend at the rate of 4½ per cent. per annum is recommended by the Board for the period from the date of reconstruction—viz., March 12, 1894—to December 31 last.

Portsmouth.—The report of the Electric Lighting Committee with reference to the proposed extension of electric mains, at an estimated cost of £21,000, has been laid before the Council and adopted without discussion.

Coseley.—The Urban District Council have, on the motion of Councillor Wones, unanimously decided that the surveyor should prepare estimates showing the cost of lighting by electricity and other methods as early as possible.

Maidstone.—A meeting has been held of the Urban District Council at which Alderman Ellis said there was no report from the Electric Lighting Committe, who hoped, however, to make a report at the next meeting of the Council.

Walthamstow.—The Board of Trade have decided to grant the provisional order applied for by the Walthamstow District Council for powers to supply electricity within the area of their jurisdiction. This order will require confirmation by Parliament before it can become operative.

Windsor.—The Electric Lighting Committee have submitted to the Town Council the provisional order which has been granted by the Board of Trade in respect to the electric lighting of Windsor and Eton. Alderman Dewe moved the adoption of the report, Councillor Burt seconded, and it was agreed to.

South Africa.—An item from Johannesburg states that the directors of the Wemmer Company have sanctioned the following expenditure on capital account: (*a*) for additional 10 stamps to mill; (*b*) for electric lighting plant; (*c*) for addition to cyanide plant (two leaching vats); and (*d*) for equipping workshops.

Submarine Cables Trust.—The sum of £1. 15s., on account of the coupon due on Monday, will be paid by Messrs. Glyn, Mills, and Co. The coupons should be left with the bankers for examination four clear days before payment.

Newmarket.—The Board of Trade have revoked the Newmarket Electric Lighting Order, 1893, as confirmed by the Electric Lighting Order Confirmation (No. 7) Act, 1893, as from March 28, 1895, the revocation to take effect from such date.

City and South London Railway.—The receipts of the Company for the week ended April 14 were £779, against £840 for the corresponding week of 1894, or a decrease of £61. The total receipts for the current period of the present half-year are £14,362 against £13,727 in the corresponding period of 1894, an increase of £635.

Pemberton.—At an extraordinary meeting of the Urban District Council, Messrs. Gaskell and Sharrock attended as a deputation with reference to their proposal to put down a small electric lighting plant for a portion of the West Ward. The further consideration of the question was adjourned until the annual meeting.

Telautograph Company, Limited.—This Company has been registered, with a capital of £42,000, to carry on the business of a telautograph, telephone, telegraph, and electric light, heat, and power supply company, and, with a view to the above objects, to enter into an agreement with the Gray European Telautograph Company.

Leamington.—A committee of the Town Council have reported that they have received a letter from Mr. F. H. Medhurst asking the committee to give him an appointment to explain the system of electric light producer and refuse destructor, but at present they do not see any reason to accede to his request. The report was adopted.

Newcastle Tramways.—The Newcastle Town Improvement Committee have received a letter from the Board of Trade intimating that, having received and considered the report of the Government inspector, they had resolved to sanction the application of the cable haulage system to the Newcastle tramways, with certain slight modifications.

Pontypool.—The Board of Trade have decided to grant the provisional order which was applied for by the Pontypool Electric Light and Power Company, Limited, for powers to supply electricity within the district of the Pontypool Local Government Board. This order will require to be confirmed by Parliament before it can become operative.

Colwyn Bay.—Messrs. Clirehugh and Dune, engineers and local agents respectively for the proposed electric tramway between Llandudno, Conway, and Colwyn Bay, have attended a meeting of the Urban Council and explained the general nature of the scheme. They asked the Council to express their approval of the principle, which was done.

Epstein Accumulators.—The increasing demand for the Epstein accumulators has necessitated the erection of a new large factory, which is now in full working order, and comprises a plant of 600 h p, enabling the company to execute even very large orders expeditiously. At the same time the prices have been reduced. Enquiries should be sent to the head office, 215, Gresham House, Old Broad-street, London, E.C.

Change of Firm.—Messrs. Edlin and Stevenson of Church-street, Cape Town, inform us that Mr. Herbert W. Edlin has retired from their business, and that it is now being carried on under the same style by Mr. A. David Stevenson, who has taken over all assets and liabilities of the firm. It is requested that creditors will furnish a statement of accounts owing to February 28, and that all accounts due to the firm up to that date be settled at the earliest moment.

Wakefield.—The Electric Lighting Committee of the City Council have recommended that tenders for electric lighting works should be obtained, and that application should be made to the Local Government Board for power to borrow £25,000 to defray the cost of the works, which Councillor J. L. Lee hopes will be carried out with as little delay as possible. The Town Council have referred to the General Purposes Committee a letter on the subject of the electric light.

Snowdon.—The construction of a railway to the summit of Snowdon is making satisfactory progress. The severe weather of the early part of the year delayed operations for several months, the mountain being covered with deep snow. There are about 200 men engaged on the construction of the railway, and presently an additional number will be employed. Earthwork for about one-half the distance has been excavated, and the resident engineer, Mr. Oswell, expresses the opinion that the line will be in operation during the greater part of the tourist season this year.

Morecambe.—The Finance Committee have reported to the Town Council the receipt of a letter from the Morecambe Electric Light and Power Company, Limited, stating that the managers of the company were open to treat for the transfer of the company's undertaking and works on equitable terms, and that the letter had been referred by the chairman of the committee for consideration. It was resolved that the Chairman of the Committee, Messrs. W. H. Bellamy, T. Baxter, and W. Harper be a sub-committee to interview the managers of the electric light works upon the subject of the letter.

Taunton.—Alderman Spiller at a meeting of the Town Council called the attention of the Council to the fact that within six weeks the Bath and West of England Show would take place at Taunton, and yet the pavements were up and many works uncompleted. It was stated that the reason of the pavements being

Digitized by Google

pulled up all over the town was owing to the fact that the electric light cables were being laid underground. Mr. Potter, chairman of the Electric Light Committee, assured the Council that all the work of laying the cables and readjusting the footpaths would be completed long before the show.

Huddersfield.—A meeting of the Town Council was held on Wednesday. The minutes showed that a deficiency arose on the revenue account of the electric lighting works of £2,065. 4s. 9d. Mr. Gee asked whether the chairman of the committee could give the Council some idea when the leakage of these works would cease. Mr. Calvert replied that they were in a better position than last year, when there was a deficit of about £2,000 for only a part of a year's working. Had it not been for the heavy rate of interest to be paid on the loans which covered a short period, there would be a profit on the works for the past year of £1,400. The minutes were approved.

Dover.—Several trials of the electric light have been made. The lights in the Town Hall were used for the first time at a Cinderella dance, and were most successful. The Dover Electric Light Company have commenced their contract for lighting a portion of the public thoroughfares of Dover by electricity. The lights used are arc lamps, and the section of the town included in their present contract is the whole of the sea-front and the main thoroughfare from the sea to the Market-place. Everyone admits that the light is very fine. The only public buildings at present lighted by electricity are the Town Hall and Buckland Church. The light was first used at the church on Easter Day.

St. Helens.—The chief clerk, Mr. Lee, reported to a meeting of the Water Committee that some time ago the Baths Sub-Committee decided to carry out certain repairs at the Warrington-road baths, but when the question was brought before the Water Committee it was decided to defer it, as the Gas Committee had expressed a desire to take over the baths premises for conversion into a building for the proposed electric lighting machinery. The Gas Committee, however, had decided that the baths would not be required. Alderman Cook said the premises were found to be unsuitable for electric lighting purposes, and the committee had decided to recommend the Council to close Rimmer-street, to pull down the cottages now therein, and to erect new electric lighting premises.

Aberdeen.—At a meeting of the Gas Sub-Committee of Aberdeen Town Council, representatives from Messrs. New and Mayne and Messrs. Shirras and Sons were heard with reference to a reduction in the charge for electric current supplied to motors. The deputation stated that several enquiries had been made on the subject, and the feeling was that the charge should be less than that for current for lighting purposes. The committee, in view of the fact that the current supplied to motors would be used mostly during the day, when very little lighting was required, agreed to recommend that the charge for the supply to motors should be 4d. per unit. It was resolved to recommend to the Gas and Electric Committee that a further lease should be taken of the shop in Union-buildings used as a gas-stove showroom, although there might be an increase of rent owing to improvements that are to be carried out.

Brechin.—The difficulty with the Scottish House-to-House Electric Lighting Company in regard to the agreement to supply electric light to the burgh has come up at a meeting of the Police Commission. A letter from the manager of the company was read with reference to the proposal that the Commission have the option to purchase the works at the end of 15 years, instead of at the end of 10 years, as first agreed upon. He said he had made enquiries as to the chances of the company obtaining financial support to carry out the undertaking, and found that such support would not be forthcoming unless the purchase could be made at the end of 15 years by arbitration, and not under the terms of the Electric Lighting Act. If this was agreed to, he thought the difficulties would be remedied. Bailie Ferguson thought that if they had the right to purchase at the end of 15 years it should be by Board of Trade terms, and moved accordingly. Mr. Jamieson seconded, and this was agreed to.

Dewsbury.—A report has been submitted to the Town Council by the Lighting and Water Committee containing the following, among other items: "March 18.—Fortnightly reports as to supply were read—viz., electrical energy 1,280 units. A payment of £908. 13s. 2d., being the final of 20 per cent. on their contract, retained for 12 months, was ordered to be made to Messrs. Siemens, electricians. April 1.—The electrical energy discharged was 1,265 units (in 10 days)." The Council agreed to allow discounts on electricity and gas accounts, and by special application two members of the electrical staff were retained without pay. Alderman Robinson, in moving their adoption, pointed out that the consumption of electric current had increased very much recently, notwithstanding that the days were getting longer. As to the minute in respect to the discounts to be allowed on gas and electric light accounts, it was passed, but not unanimously. Councillor Wilkinson seconded the motion, and the minutes were confirmed.

Cardiff.—A meeting of the Cardiff Lighting Committee was held on Tuesday, the mayor (Alderman P. W. Carey) presiding. Several applications for the electric lighting of private houses in Cathedral-road, Newport-road, Tredegarville, and Charles-street were received. The committee agreed to extend the mains up Newport-road as far as the corner of Castle-road, through Westgrove to Mr. Howell's new house at the lower end of Richmond-road, and through Charles-street to the baths in Guildford-crescent. The estimate for the Newport-road section was £1,500 and for the Charles-street section £360, and it was resolved that the Finance Committee be asked to arrange to borrow those amounts. Alderman Lewis remarked incidentally that the electric light in Cardiff was the weakest he had seen, and this he attributed to the opaque lamps. The Mayor stated that the opaque lamps were considered to be the best. Clear glass had been tried in the Hayes, and was a failure. Besides, Major Cardew, R.E., who came down from the Board in connection with the telephone wires, and was an expert on electricity, stated that the lamps and street-lighting at Cardiff were as good as any in the country.

Change of Address.—Messrs. Callender's Bitumen Telegraph and Waterproof Company, Limited, inform us that, owing to the great increase in the business of this company, it has been found necessary to remove the offices from their present address to larger premises which they have taken at 90, Cannon-street, E.C. In order to cope with their increasing business, the directors have appointed Mr. Theodor Petersen as assistant manager to Mr. T. O. Callender. Mr. W. Douglas Reid, who has been connected with the company for the past 10 years on outside works, has been appointed resident engineer to superintend the carrying out of all works in the home district, and will be found at 90, Cannon-street. The business in the Liverpool district will be in charge of Mr. F. A. Pocklington, whose office will be at Oldham-place, Renshaw-street, Liverpool. The work in the South Midlands and West of England will be in charge of Mr. George Barnard, whose office will be at 58, Water-street, Birmingham. Mr. Burton, whose offices are at Lichfield House, Wolverhampton, and Talbot-street, Nottingham, will be in charge of the North Midland district. Mr. W. Moir, whose address is 28, Charlotte-street, Ayr, N.B., will have charge of the firm's work in Scotland.

Appointments.—The St. Pancras Vestry require the services of a chief electrical engineer, competent to undertake the charge and management of the whole of the Vestry's generating and distributing stations and mains, and capable of designing and carrying out all extensions and new works in connection with the private and public lighting in St. Pancras Applicants are to state age and qualifications, and to forward copies of three testimonials (not originals). Salary £600 per annum. Applications to be sent to Mr. Pycraft, marked "Application for Chief Electrical Engineer," on or before May 2.—The Vestry of St. John, Hampstead, are prepared to appoint an electrical engineer to superintend the whole of their electric lighting undertaking in the above parish. His duties will be to take charge of the central electric light station, to prepare plans and estimates, and to superintend the carrying out of all future extensions of the undertaking in the parish. He must have actual practical experience of alternating-current central-station work. He must devote the whole of his time to the duties of the appointment, and will be required to reside in the parish. Salary to commence at £300 per annum. Applications, stating age and previous experience, together with copies of not more than three testimonials of recent date, to be addressed to the vestry clerk, and endorsed "Electrical Engineer," not later than May 2.

Southport.—A meeting of the Town Council has been held at which Councillor Hesford proposed the adoption of the minutes of the Electric Lighting Committee, who recommended the acceptance of tenders for engines, alternators, and cables. He had received a letter from Councillor Baxter asking questions as to the tenders which had been sent in, and in reply he had to state that as to the engines two tenders were invited, two sent in, and the lowest was accepted. As to the alternators, one tender was invited and it was accepted. It was not every machine which would work with those they had, and they were advised by experts that the machine recommended would tend to remedy the little difficulty they had experienced at the works. Councillor Todd seconded the motion. Councillor Baxter said he was surprised that an order amounting to £2,550 should have been given after inviting only two tenders. There were in Lancashire, not two, but about a dozen makers of the engines required, and from his knowledge of engines he knew that engines of equal power, if not a little more, could be obtained for £2,000. He was not prepared to vote for any such ridiculous sum, and he would propose that the minute be referred back to the committee. Councillor Holland seconded the amendment for the sake of discussion. Councillor Boocock supported the minutes. Councillor Hesford said it was an undoubted fact that they could buy engines of the same nominal power for less money, but who was to adjudicate. They were placing the order with a good firm upon whom they could rely, and the cost per horse-power would be somewhat less than the cost of their present engines. It was important that they should have one of their new engines running by September 15, and that would be secured by dealing with the present firm.

Middlesbrough.—The Electric Lighting Committee of the Town Council have recommended that the question of electric lighting should be deferred. Alderman Jones, in moving the adoption of the minutes, while agreeing with the recommendation, said that with the number of tradesmen who were prepared to adopt the electric light they could start with three times the number of customers originally obtained by the Corporations of Newcastle and Bradford. He would at the next meeting ask them to come to a definite decision, and either apply for a provisional order or cease to play the part of the dog in the manger. Councillor Baker seconded the motion. Alderman Hugh Bell thought they should start a relatively small station, which would cost between £10 000 and £20,000, and which would supply something like 3,000 lights. They could then feel their way in the direction of the demand which was likely to arise. They were nearly at the end of their tether with the gasworks, and the starting of such a station would relieve them from the important

Digitized by Google

question of providing another gasmaking establishment. He moved that the Electric Lighting Committee should supply an estimate of the cost of a installation as he had suggested. Councillor Theo Ward seconded. Alderman Bulmer opposed the amendment, and said the light had failed to pay in several towns. Councillor Brewster did not think the committee were proposing a course which the Corporation should take. Alderman Jones said Alderman Bulmer was absolutely wrong in saying that the electric light in 20 towns had not paid. He suggested that Alderman Bell should withdraw his amendment, and said the committee would have something positive to bring forward at the next meeting. Alderman Bell withdrew his amendment, and the minutes were adopted.

St. Pancras.—At the St. Pancras Vestry meeting held on Wednesday, Mr. Churchwarden J. Thornley, J.P., presiding, the Electricity and Public Lighting Committee presented a statement of accounts for the year ending December 31 last, and drew attention to the very satisfactory result of the past year's working. The generating expenses in 1893 amounted to £6,103. 4s. 1d., and in 1894 to only £73. 5s. 10d. in excess of this amount, while the increase in the current sold to private consumers reached £2,510. 12s. After paying all charges for repairs and maintenance, including rates and taxes, there was an available balance of £7,233. 1s. 4d. to meet the interest and payments of the instalments off loans—viz, £5,379. 19s. 2d., comprising interest on the bank overdraft. Hence, there was a net profit on the year's working, after providing for bad debts, etc., of £1,753. 18s. 2d. This sum, with the amounts paid for interest and repayment of loans, was equivalent to a dividend of over 6 per cent. on the capital expenditure, and would be available for distribution to the shareholders if the undertaking belonged to a company. The committee considered that the sums paid off loans by St. Pancras in 1894 was equal to nearly 2 per cent. on the capital expenditure, and was equal to the sum set aside for depreciation by three London companies who were working on similar systems to that in St. Pancras, while if comparison was made with the total capital expenditure of the whole of the London companies it would be found that the amount set aside by them for depreciation was under 1 per cent. The charge for public lighting during the year, although more lamps had been erected, was reduced by £515. 16s. 11d. in one quarter owing to the charge being reduced from 6d. to 5d. per unit. Current sold to private consumers at 3d. per unit realised £1,236. 13s. 9d., and at 6d. £10,819. 15s. 9d. At the instance of Mr. A. Sweet, chairman of the committee, the report was adopted, after an expression of satisfaction on the part of the Vestry that it possessed so prosperous a commercial undertaking, which it was estimated could now be sold at a profit of £30,000.

Edinburgh.—A special meeting of the Edinburgh and Leith Gas Commissioners was held on Tuesday, Lord Provost M'Donald in the chair. Councillor Mackenzie, who attended at the request of the Lord Provost, made a short statement to the Commission in his capacity as convener of the Edinburgh Corporation's Electric Light Committee. There was, he said, a slight explosion in Frederick-street, in reference to which a letter had been received saying that the gas leak was due to the operations of the electric light department. They did not deny that. They were quite willing to admit that such leaks had been caused. It could not have been otherwise with operations of such magnitude. But what he wanted to point out was this, that under the new condition of things the method that had hitherto been in use in looking for leakage with naked lights was very dangerous, not only to the public, but it might also cause great damage to the electric mains and interruption to the current. They, therefore, hoped that the Commissioners and their engineers would issue instructions that some other method should be adopted of looking for leaks. They were not dictating in any way; but they were most anxious that everything should be done to prevent the risk of explosions. Bailie Kinloch Anderson assured Mr. Mackenzie of the co-operation of the Gas Commissioners. As a matter of fact, the engineers had instructed the men not to use naked lights, but in the case referred to that had been disregarded. The engineers would issue fresh instructions, so that such a thing would not occur again But he would suggest to the Electric Light Committee that the culverts and manholes should be ventilated, and if that were done he thought it would obviate risk of explosion. In reply to a commissioner, Bailie Kinloch Anderson said the only other way of looking for a leak was by smell. Councillor Mackenzie said they were under obligation to the Board of Trade to ventilate the manholes, but it appeared that certain of the explosions which occurred in London were in comparatively open and ventilated places. In consequence, the opinion of the Board of Trade inspector, Major Cardew, had been entirely changed, and his view now was that immunity would be best secured by plugging up the ends of the culverts so as to prevent the gas from travelling, and by filling the box with some non-combustible material so as to prevent the gas from accumulating. That was now being done in Edinburgh.

Ealing.—The Electric Lighting Committee have reported that the surveyor had informed them that he had attended the electric light station, and formally, on behalf of the Council, taken over the working. Messrs. Bramwell and Harris had written that as the electric light works under the original contracts were virtually completed, their further association with the Council professionally in the matter would be as consulting engineers, and they suggested an appointment for five years at £105 per annum. The committee had come to the conclusion that for some time to come the services of an experienced consulting engineer would be necessary, and they recommended the appointment of Messrs. Bramwell and Harris for a term of three years at £105 per annum, this fee to include all travelling and incidental expenses A letter had been received from Messrs. Callender and Co. relative to damage done to the centre arc posts by carts coming along the road with the drivers fast asleep, and it had been decided that the matter should be brought to the notice of the police. The committee further reported the consideration of a letter from the Brush Company regarding the laying on of current to a house in North Common-road. The committee considered that a main should be laid on so as to serve this particular road; the line of main would be from the transformer on Ealing Green, along the Grange-road and the west side of the common to Uxbridge-road. This course would enable several houses to be taken on the route, would deal with the several road lamps, and provide for the lighting of the whole of the North Common-road. The supply would be for about 1,200 8-c p. lamps, and the cost about £650. The committee recommended that this work be proceeded with. A letter had also been received from Mr. Stuart asking that his house in Florence-road might be connected with the main. As the house was outside the specified distance, Mr. Stuart offered to pay the excess amount of £30, the money to be refunded to him in three annual payments. The committee recommended that this be done. Mr. Pritchard moved that the appointment of Messrs. Bramwell and Harris as consulting engineers be deferred until after the final settlement of the accounts in connection with the electric lighting works. The other members of the Council appeared to feel that nothing was to be gained by this proposal, and it was not seconded. The report of the committee was then adopted. A proposed improvement (suggested by Mr. Green) in the roadway on Ealing Common, to be carried out in connection with the contemplated laying of an electric light main, was referred to the Works Committee for consideration; and a plan suggested by Mr. Hedges for the better protection of the centre road electric lighting lamps was referred to the surveyor, who expressed his opinion that the plan proposed would be a very good one in more effectually protecting the standards and the erections on which they were placed. A communication from the parish of St. Mary, Islington, regarding explosions in electric lighting conduits through escapes of gas from gas-mains, was referred for consideration to the Electric Lighting Committee.

Croydon.—The General Purposes Committee of the Croydon County Council have presented the following report: '(*a*) That the Electric Lighting Sub-Committee be authorised to instruct the town clerk to make application to the Local Government Board for permission to borrow a sum not exceeding £27,500 for the purpose of electric lighting. (*b*) That the sub-committee be authorised to instruct Prof. Kennedy to arrange with the British Thomson-Houston Company a detailed specification of such works as in the judgment of Prof. Kennedy will satisfactorily supply electricity to the central area, together with all necessary accessories at such contract price as Prof. Kennedy may approve. Provision will be made, as far as buildings and laying pipes to carry extra mains are concerned, for a considerable future extension of the system. (*c*) That the sub-committee be authorised to order the corporate seal to be affixed to a contract with the British Thomson-Houston Company, Limited, subject to the sanction of the Local Government Board to a loan for the purpose of providing the necessary expenditure. (*d*) That in the event of the British Thomson-Houston Company, Limited, not being willing to enter into a contract for carrying out the revised specification at a price which is satisfactory to Prof. Kennedy, the sub-committee be authorised to abandon negotiations with that company and to enter into fresh negotiations with the firm whose tender is above referred to, reporting, however, to the Council before any contract with that firm becomes binding. (*e*) That the sub-committee be authorised to engage Prof Kennedy to watch the interests of the Corporation in the matter and to see that the contract is efficiently carried out. (*f*) That the sub-committee be generally authorised to make such arrangements for carrying out an installation for the central area as they may find necessary or expedient." The committee have added the Mayor and Alderman Thrift to the sub-committee. After a lengthy discussion the report was adopted. The usual monthly meeting of the council of the Croydon Chamber of Commerce has been held, at which the assistant secretary presented a report detailing the result of the canvass recently undertaken by the Chamber in reference to the electric lighting question, with a view to ascertaining the views of the residents in the compulsory area and in the locality immediately contiguous as to the amount of support the electric light would be likely to receive if introduced into the town, and as to whether the opinion of the traders of the town is in favour of the undertaking being worked by a private company or by the Corporation The replies received from the whole of the residents addressed both inside and outside the compulsory area may be totalled as follows as being the net result of the canvass: total number of circulars sent out, 804; total replies received, 369; number who replied yes to the question, "Would you be likely to use it?" 146; number who replied with a qualified "yes," such as "Depends on the price," 74; number who replied "no," to same question, 121; in favour of the Corporation carrying out the works, 244; in favour of a private company, 53. Replies in the affirmative in answer to the first question have been received from the representatives of the following: Public Hall, Croydon National Hall and Circus, Girls' High School, Croydon Theatre Royal, Croydon Conservatoire, and the churches of St. Matthew and St. Michael and all Angels, the Free Christian Church, and St. Mary's Catholic Church.

Weston-super-Mare.—A meeting of the Urban District Council has been held at which a report was presented showing that at a

Digitized by Google

committee meeting of the whole Council, held on 4th inst., a letter dated March 29 was received from Mr. F. H. Medhurst proposing that the electric lighting provisional order be transferred to a company, to be formed forthwith by himself, on the following conditions—viz.: (1) The company to pay the Council 400 guineas for the provisional order on the signing of the agreement between the Council and the proposed company. (2) The Council to have the option of purchasing the undertaking at the end of five years, and at the end of every subsequent period of two years. (3) In the event of the Council exercising the first option, the amount to be paid by the Council to the company to be equivalent to the amount expended by the company plus a bonus of 15 per cent.—in other words, the Council would, in the event of its exercising its option at the expiration of five years, pay the company £115 for every £100 of capital legitimately expended by the company on the undertaking. If the Council decide to purchase the undertaking at the end of seven years, or at the end of any subsequent period of two years, the amount to be paid to be equivalent to the capital expended by the company plus a bonus of 10 per cent. If the Council purchase the undertaking at the expiration of 42 years, then they would pay the then value of the undertaking without any allowance whatever for goodwill or compulsory purchase. (4) The company to undertake not to charge more than 6d. per unit for private lighting. (5) If the Council decide to entrust the company with public lighting the amount to be paid by the Council to the company per arc lamp of 2,000 c.p. per annum to be £20. But it shall not be compulsory for the Council to give the company any public lighting whatever. (6) The Council to undertake to supply the company free of charge with all the refuse of Weston-super-Mare, and to pay the company the sum of £60 per annum for thoroughly disposing of the same without creating a nuisance in a suitable refuse destructor. At present the cost to the Council is about £60 per annum for pumping, wages, etc., at the refuse pits. The above conditions apply to the electric lighting and refuse destructor schemes, but the company would be prepared, with the consent and approval of the Council, to apply for a tramway provisional order from the station to the pier, and to lay down immediately on receipt of the said provisional orders a suitable electric tramway for that distance. It is understood that in the event of the Council exercising the first or any of the options for pre-emption, the same conditions would apply to the tramway as to the electric lighting and refuse destructor schemes, and the Council would be bound to purchase the whole undertaking of the company in its entirety whenever they decide to exercise their option. Whilst the company would be willing and even anxious to carry out the electric tramway above mentioned, it would, nevertheless, not make this part of the scheme a *sine qua non*, and would be prepared, if the Council preferred, to carry out the electric lighting and refuse destructor scheme alone. Mr. Medhurst's letter concluded by stating, "I shall be pleased to have an early opportunity of discussing this question with your Council, and I wish especially to point out that my offer is not in any sense to be taken as an ultimatum, but that it is capable of modification if such modification is thought necessary by the Council and is considered possible by me." It was proposed by Councillor Gill and seconded by Councillor Dubin, "That in the opinion of this committee it is not desirable that the Council should transfer the powers, etc., conferred upon them by their electric lighting provisional order, but should retain same in their own possession in order to carry them out as soon as they consider themselves in a position to do so." It was proposed by Councillor Deverell, and seconded by Councillor Phillips, "That before we proceed to vote on this question, Mr. Medhurst be invited to come into the Council-room." This being lost by eight votes to six, the original motion was carried.

PROVISIONAL PATENTS, 1895.

April 8.

7142. **Improvements in regulating transformers for alternating currents.** Manchester Edison-Swan Company, Limited, Alfred Still and Edward Woodrowe Cowan, Temple-chambers, Brazennose-street, Manchester. (Complete specification.)

7147. **Improvements in telephone receivers.** John Graham, 46, Belmont-street, Haverstock Hill, London.

7152. **Improvements in the mode of and means for writing by telegraphy, which he terms the pantelegraph.** Julius Victor Faber, 77, Colmore-row, Birmingham. (Complete specification.)

7191. **Improvements in electric arc lamps.** Henry James Fisher, 70, Chancery-lane, London.

April 9.

7245. **Improvements in electric railways.** John Henry Guest, 52, Chancery-lane, London. (Complete specification.)

7278. **Improvements in or relating to electric conductors.** Christian Hamilton Gray, 323, High Holborn, London.

April 10.

7315. **Improvements in and connected with electrical storage batteries.** William Joseph Starkey Barber-Starkey, 70, Market-street, Manchester.

7364. **Improvements in the electrolytic manufacture of alkali-chlorates.** Jasper Wetter, 433, Strand, London. (The Elektrizitäts-Aktiengesellschaft vormals Schuckert and Co., Germany.)

7319. **Improvements in and relating to electrical hot-plates.** Thomas Fletcher, William Russell, and Fletcher Russell, and Co., Limited, 70, Market-street, Manchester.

April 11.

7445. **Improvements in accumulators.** Daniel Edward Hipwell, 8, Quality court, Chancery-lane, London.

7458. **Improvements in the electrolysis of metallic salts.** Carl Kellner, 46, Lincoln's-inn-fields, London.

April 13.

7504. **Improvements in and relating to the distribution of alternating currents.** Galileo Ferraris and Riccardo Arnó, 45, Southampton-buildings, Chancery-lane, London.

7525. **An electrical jacquard apparatus for use in curtain-lace machines and fancy looms.** William Sissling, 25, Prince-street, Long Heaton, Derbyshire, R.S.O.

7548. **An electric safety switch.** Siemens Brothers and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.) (Complete specification.)

SPECIFICATIONS PUBLISHED.

NOTES.

The Chitral Expedition.—The field telegraph has been in use in connection with these operations.

Personal.—Mr. E. O. Walker, C.I.E., has entered upon his duties as superintendent of telegraphs, Ceylon.

Tramways (Local Authorities) Bill.—This Bill has been read a second time in the House of Commons.

Municipal Electric Lighting.—Various London vestries are accused by *London* in its last issue of apathy in the matter of progress as regards electric lighting.

Exhibition at Paris.—It is intended this year to hold an International Sanitary Exhibition in Paris. The offices are at 103, Boulevard Haussmann, Paris. Class 2, dealing with municipal hygiene, includes an electricity section.

Electric Traction in France.—The first trials on the electric tramway line at Lille have taken place on the portion between the Laboureur Bridge and the Palace de Wattrelos. The whole system will be in operation shortly.

Electric Lighting in Switzerland. — The Uri authorities are considering an application of Mr. Usern to utilise the power of the Oberalpreuss for the electric lighting of Andermatt and Hospenthal, and for electric traction purposes.

Electric Traction in Germany.—Authority has been received by Messrs. Siemens and Halske for an electric tramway in Berlin from Warschauerstrasse to Nollendorfplatz and Potzdamerplatz. This is to be an overhead railway.

"What's in a Name?"—Mr. Nelson W. Perry, the well-known American electrical engineer, is designated in a gas contemporary as Melsoon W. Perry. But one does not expect accuracy from a gas paper when it touches upon anything of an electrical character.

Telegraphy in India.—India and China are now in direct telegraphic communication *viâ* Bhamo and Moulmein. The telegraph line between Kulu and Mundi has been thoroughly repaired and re-aligned. The new line being shorter, a saving in material has been effected.

Electro-Medical Instruments.—We have received from Messrs. A. Hurst and Co., 66, Fenchurch-chambers, E.C., a catalogue of their electro-medical instruments, including galvanic batteries, portable constant-current batteries, etc. There is nothing of the "Harnessing electricity" about these.

Students' Meeting.—A meeting of the students of the Institution of Electrical Engineers will be held in the library of the Institution, 28, Victoria-street, on Friday, May 3, 1895, at 8 p.m., when the following paper by Mr. A. C. Eborall will be read: "Single-Phase Alternate-Current Motors" (with illustrations, etc.).

Foremen Engineers.—The anniversary dinner of the London Association of Foremen Engineers and Draughtsmen will be held to-morrow (Saturday), in the Great Hall, Cannon-street Hotel, at 6 p.m. The chair will be taken by the Right Hon. H. Campbell-Bannerman, M.P., whilst Mr. Alexander Siemens, M.I.C.E., will occupy the vice-chair.

Institution of Electrical Engineers.—No. 116 of the *Journal* of the Institution has been issued. Among other matter, it contains the papers by Mr. W. B. Sayers on "Reversible Regenerative Armatures and Short-Air-Space Dynamos," and by Dr. John Hopkinson on "Propagation of Magnetisation in Iron," and the discussions thereon.

Holborn Restaurant.—A well got-up illustrated *brochure* has been issued by the proprietors of the Holborn Restaurant, the letterpress being by Mr. Frederick Leal and the illustrations by Mr. Horace Morehen. As our readers probably are aware, the establishment is lighted electrically throughout, and among the illustrations is one of the machinery-room.

School-Lighting.—At the Sanitary Conference which was opened at Manchester on Wednesday, Dr. Emrys Jones read a paper on "The Lighting of Schools," in which he urged the adoption of the electric light in schools. In the course of the discussion, the chairman, Dr. Maclure, expressed concurrence in the view that the electric light should be used in preference to gas.

Electric Lighting in Hungary.—Messrs. Egger and Co. are fitting up a private installation in the Königs Brewery in Budapest, which is one of the largest breweries in the country. The plant is at present to be for the supply of current for 1,200 incandescent lamps and for various electric motors.—A limited liability company has been formed for the erection of a central station at Ujhely.

Electric Transmission in Germany.—For a long time there has been a scheme spoken of for the establishment of a central station near Berlin for the service of the various villages of the Upper Spree. The consent of the local authorities has now been obtained, and the Allgemeine Elektricitäts Gesellschaft will proceed with the work. The main object of the installation is to supply power to manufacturers.

The "Desecration" of Nelson's Column.—The *Daily Chronicle* states that as the result of action taken by the local authorities, in conjunction with the Office of Works, the "desecration" of Nelson's Column and public buildings in Trafalgar-square by advertisers, by means of search-lights, has been stopped. If this statement be true, it shows somewhat absurd sentimentality on the part of the Office of Works.

Rating of Machinery Bill.—The fact that the Rating of Machinery Bill passed through Grand Committee at a single sitting without alteration has not modified the opposition with which it is regarded in some quarters. When it comes on for third reading Mr. James Lowther will move that it be recommitted to a committee of the whole House. Mr. Powell Williams, going a step further, will move its rejection.

Gray's Improved Telautograph. — We are informed by the General Electric Company, Limited, that a line for the transmission of handwriting by this machine, has now been erected between their warehouses, 69 and 71, Queen Victoria-street, E.C., and the offices of the Telautograph Company, 13, Victoria-street, S.W., (a distance of from two to three miles), at either end of which is a transmitting and receiving instrument.

A Marvellous Incident. — Several daily papers report a phenomenon as follows: "Electric Fuses Explode.—An alarming explosion occurred yesterday afternoon on the premises of Mr. A. W. Bennett, electrical engineer, East-parade, Leeds. It appears that a number of fuses which were being packed suddenly exploded, causing a report which was heard for a considerable distance, and seriously injuring a youth named Humphreys."

Electric Lighting in Bombay.—The *Times of India* says that proposals for lighting the residency, "Westward Ho," the Holy Trinity, St. Mark's, St. Andrew's, St. John's, the Wesleyan Churches, and several regimental messes with electric light are now under favourable consideration, and Mr. Simpson, superintending electrician of the Oriental

Digitized by Google

Electric Light Company, has been asked to survey the residency, churches, etc., and to submit estimates.

Books Received.—We have received from Messrs. Crosby Lockwood and Son, of Stationers' Hall-court, E.C., "Electric Light for Country Houses," by Mr. John Henry Knight. It is described as a practical handbook on the erection and running of small installations, with particulars of the necessary cost of plant and working. Messrs. Longmans, Green, and Co. have published "Motive Powers and their Practical Selection," by Mr. Reginald Bolton.

Light Railways.—According to recent returns, light railways are a decided success in Sweden. The quinquennial return just issued shows that the average earnings of the Swedish light or narrow-gauge railways is £140. 15s. 6d. per kilometre, and the traffic expenditure £82. 11s. 6d., leaving a net surplus of £58. 4s. The average cost of construction has been £1,681 per kilometre, so that the return on the capital expended should have averaged 3·46 per cent.

Society of Arts.—The arrangements for next week are as follow: on Monday, 29th inst., Cantor Lectures; "Recent American Methods and Appliances Employed in the Metallurgy of Copper, Lead, Gold, and Silver," by Mr. James Douglas—(Part II., "The Calcination of Ores and Chlorination of Gold and Silver); and on Wednesday, May 1, "Deviations of the Compass," by Prof. A. W. Reinold, when Dr. W. Anderson, F.R.S., vice-president of the society, will preside.

New Instrument Wanted. — Lieutenant-Colonel Yorke, who has issued his report to the Board of Trade on the Great Northern Railway accident at Wood Green, says: "What seems to be required is some test, possibly either by means of electricity or sound, which could be readily applied at suitable intervals to each individual axle, by which it can be ascertained whether the axle is structurally perfect throughout." It would be interesting to know what has become of the schiseophone.

Bordeaux Exhibition.—The London Chamber of Commerce are informed that it is officially announced in Bordeaux that the Bordeaux International Exhibition will be open to the public on and after Saturday, May 4, and intending exhibitors who have already had space allotted to them, but have not yet sent their goods to Bordeaux, are reminded that if exhibits are not received at Bordeaux in due time, the exhibition authorities will consider themselves at liberty to dispose of such space otherwise.

Imperial Institute.—Saturday, May 11, was fixed at the last meeting of the executive council for the opening of the summer season, and it was reported that the whole of the available space for the exhibition of railway appliances and inventions had been allotted, and that it had been impossible to meet several applications. It was announced that progress had been made with the arrangements for the exhibitions of photography in its relation to art, science, and industries, and the collection of the Duc d'Orleans.

Explosions.—An interviewer of the *City Press* has been discussing Major Cardew's Southwark Bridge report with a gentleman who is vaguely described as "the secretary of a well-known electric lighting company." Internal evidence shows that he is an official of the City of London Company. The anonymous gentlemen interviewed came to the conclusion that the gas companies ought to be under the supervision of the Board of Trade as well as electric lighting companies, and should be obliged to take measures to prevent the escape of gas.

Electrical Engineering in Persia.—With reference to the Persian concessions that have been made to Americans, the American Vice-Consul General at Teheran reports to the State Department that an American citizen holds concessions for drilling artesian wells for irrigation purposes throughout Persia, and for the introduction of electricity in its various forms outside of telegraphy, which already exists in that country. The concessionaire has not, however, been able to secure sufficient capital to push these enterprises to a successful issue.

Electric Cooking and Heating Apparatus.—The Electrical Company, Limited, 122 and 124, Charing Cross-road, send us an illustrated catalogue of their electric cooking and heating apparatus. It commences with general remarks on the subject for the benefit of the general public, together with instructions. The list includes electric hot-plates, plate-warmers, electric boilers (for being dipped into the liquid to be heated), pans, frying-pans and saucepans, coffee-cans and tea-kettles, grills, flatirons, cooking-stoves of various designs, cigar-lighters, etc.

South Africa.—A meeting of the Durban Town Council has been held at which the Finance Committee recommended that the necessary steps be taken for the issue of a loan of £100,000, at 4 per cent., to be placed in the London market for carrying out the electric lighting for the town, purchase from the War Department of lands for the construction of a bay esplanade, and the completion of the Umlaas Waterworks. After a long discussion, in which some members seemed disinclined to support all the projected improvements named, as representing too large a programme, the question was referred to a committee of the whole Council.

West of Scotland Iron and Steel Institute.—The annual general meeting of the West of Scotland Iron and Steel Institute was held last Friday evening in the Andersonian Buildings, Glasgow, Mr. James Riley, president, in the chair. The report by the council bore that 41 members had been admitted during the session, and after allowing for removals from various causes there was a net gain in membership of 31, the total on the roll being 187 members. In every way the session had been a gratifying success. Prof. A. Humboldt Sexton was elected president for the ensuing year. Mr. George Ritchie afterwards read a paper on water gas.

Electric Lighting at Rangoon.—A new Government house is being completed at Rangoon for the Chief Commissioner of Burma. The whole building is to be lighted by electricity. The entire plant has been ordered through the Secretary of State. The Irrawaddy Flotilla Company have the contract for fitting up the installation, and have laid all cables and wires throughout the house. With reference to the tenders which are being invited for the electric lighting of Rangoon, *Indian Engineering* states that it will have to be done by a concession to a reliable company, as the municipality cannot afford to meet its cost at present out of revenue derived from taxation.

Transmission of Power.—We understand that Mr. W. C. Johnson, of the firm of Johnson and Phillips, is about to lay down a transmission of power plant in Wales. Mr. Johnson has taken great interest in the gold-mining industry in Merionethshire, and has secured several claims. To develop these he proposes to utilise the water power of a small salmon stream, and to transmit some 200 h.p. to the mines of an electrical plant somewhat similar to that recently supplied by the firm to the Sheba Gold Mining Company. The distance of transmission will be about two miles. At present a five-stamp mill is being fixed, but this will be added to should sufficient payable ore be found.

Playing Tricks.—A Dover paper is responsible for the suggestion that the electric light manager there is a

Digitized by Google

practical joker. The other Sunday night, the story runs, about 9 o'clock, "the promenaders on the sea-front were somewhat startled at the sudden disappearance of the electric light, all the lamps almost instantaneously ceasing to cast their light upon the scene. The stoppage naturally caused much comment, but tongues were soon set at rest by the reappearance of light in a few minutes, as brilliant as before. The cessation was not due to any fault in the machinery, or any defect in the wires, but was simply the result of an experiment on the part of the manager of the company. He wished to show the public the difference between the new illuminant and gas, and took this method of demonstrating it. A similar experiment was made at the Town Hall during the Primrose League 'At Home.'"

Mitchell's Newspaper Press Directory.—We have received a legal notice from Messrs. McKenna and Co., on behalf of Messrs. Mitchell and Co., that our note on this directory in our issue of April 5 is incorrect. We sorrowfully acknowledge that we were incorrect so far as to the remarks concerning *Electricity* and *Lightning*. The titles of these publications really do appear, first in the list of contents, where *Electricity* is given as a monthly—which of course it is not—secondly, among "Class Papers and Periodicals," where, however, *Lightning* appears as *Lighting*. We fallible mortals thought to find the names under the head of London papers, p. 41—but we suppose the *Electrical Engineer*, *Electricity*, and *Lightning* are not London papers. The titles are not found among the list of weekly newspapers (p. 33) nor among the papers published in London (pp. 66 and 72). We regretfully acknowledge our error in not seeking the titles of what we deem weekly trade papers—among the list of "magazines, reviews, and periodicals."

A Discoverer.—Mr. C. A. Pearson, of *Pearson's Weekly*, is a great discoverer—by which, of course, we do not mean a great inventor. But from time to time he discovers and publishes accounts of most marvellous inventions. His latest "find" is an inexhaustible primary battery. He, or one of his subordinates, writes: "The invention of the portable incandescent lamp some years ago promised to be of the greatest service to men who habitually travel in the semi-darkness of our English railway carriages. In this, however, we were disappointed. The constant necessity of sending the accumulators to be recharged made what would have otherwise been a luxury into a nuisance. Mr. H. F. Phillip, of Guildford, has now patented a pocket primary battery, designed especially with the intention of overcoming this difficulty. His battery is precisely the same size as the ordinary accumulator, but requires absolutely no recharging, acids, or attention. It is equally useful, of course, for motors, bells, medical coils, telephones, and so on. The strangest part of this invention, to my mind, is the fact that it is new." But supposedly inexhaustible primary batteries are not new. Mr. Pearson for a time ran *Industries and Iron*, and should therefore really know better.

Wood a Double Refractor for Hertzian Waves. Herr K. Mack, working in the Hohenheim Physical Institute, has succeeded in demonstrating the occurrence of double refraction of electric waves in wood. That electric waves, unlike light waves, are capable of penetrating wood was already found by Hertz. "It is not without surprise," he says in his classical work on the "Propagation of Electric Force," "that one sees the sparks appear inside a closed room." But the fact that waves of electric force are transmitted in a different manner accordingly as they vibrate across or along the fibre of the wood has only just been proved by Herr Mack, who gives a full description of his method in a recent number of *Wiedemann's Annalen*. It is well known that two Nicoll prisms transmit no light when their principal plates are crossed, but that light may be made to appear by inserting a doubly-refracting substance between them. For the Nicoll prisms substitute Hertzian concave mirrors with their focal lines crossed, and, instead of the tourmaline or other doubly-refracting substance, insert a plate of wood 10in. thick, with its fibre at 45deg. to each of the focal lines, and you have Mack's apparatus. The sparks, which are extinguished on crossing the two focal lines, reappear on inserting the wood in the manner indicated. This striking experiment forms another important link in the chain connecting the domain of light with that of electricity.

Mining Institute of Scotland.—The eighteenth annual meeting of the institute has been held at Hamilton, Mr. George A. Mitchell, president, in the chair. The council's report for the past year showed substantial progress, the membership being 487, against 481 last year. The expenditure had exceeded the income chiefly owing to unexpected calls from the federation. The balance on hand was £127. 19s., as against £155 last year. The office-bearers, as nominated at last meeting, were elected, and the president returned thanks for his re-election, and delivered an address, in which he dwelt on the importance of the institute in the discussion of mining matters. He referred to the loss since last meeting of Mr. Archibald, Cambuslang, a member of council, and a memorial minute to be sent to deceased's widow was approved of. Mr. James Wallace, Wester Gartshore Colliery, Kirkintilloch, was nominated as his successor for election at next meeting. The president, instead of delivering a formal address, read a paper entitled "Electric Coal-Cutting at Glenclelland Colliery." The discussion of the paper was adjourned. Brief discussions took place on papers read at a former meeting by Mr. A. M. Grant on "Winding Engines," and Mr. J. G. Barclay on "The Barclay Crown Valve Exhaust Gear" and an "Overhanging Beam Pumping Engine," and were adjourned. The secretary, in the absence of the author, Mr. Dugal Baird, read a paper on "Pumping-Engine Velocity Diagrams." The discussion was adjourned.

A Large Electric Locomotive.—In the March number of the *Transactions* of the American Institute of Electrical Engineers is a description by Dr. Cary T. Hutchinson of a large electric locomotive which has just been finished by the Baldwin Locomotive Works. This locomotive has eight drivers connected rigidly by side bars, making a wheel base of 16ft., the length over all being about 30ft. The weight is 133,000lb., uniformly distributed on the eight drivers, giving 16,700lb. on each driver. There are four motors, one on each axle, the motors being built directly on the axle without springs of any kind between the armature and the axles. The machine has a capacity on a four-hour test of 1,000 h.p. at a speed of 35 miles per hour. The regulation is the series-parallel, the motor being (1) all in series, (2) two series by two in parallel, (3) all four in parallel. There is also a resistance intended for use on first position in starting. The lowest speed, without resistance, is about seven miles per hour. A test recently made at the Baldwin Locomotive Works showed an efficiency of more than 92 per cent. when operating 1,000 h.p. The motors are designed so that they will work without sparking with full current in the armature at one-half normal field strength. That is to say, they will operate at any speed from 35 miles per hour up to about 65 miles per hour at the same power, the drawbar pull varying inversely as the speed. At speeds below 35 miles per hour the drawbar pull is constant, the power, therefore,

Digitized by Google

being directly proportional to the speed. The smoothness and absence of vibration was very noticeable in the test referred to. The entire machine was supported on four jacks without bracings; when running with full torque there was scarcely any shaking.

New Arc Lamp.—Mr. Henry Chapman, 69, Victoria-street, S.W., is introducing into this country the Wilbrant arc lamp, made by a Brussels firm. The mechanism feeding and regulating the carbons is simple, there being no gearing, cords, or chains. The lamp consists of a frame of two stout brass rods, terminating in flat plates top and bottom. The lower plate supports a small electromagnet, through the core of which passes the shank of the lower carbon-holder. When no current is passing through the lamp this holder and its armature are forced away from the magnet by a spring, thus bringing the lower carbon into contact with the upper one. When a current passes through the lamp, the magnet pulls the holder down against the resistance of the spring, striking the arc. The feeding is regulated by a second electromagnet affixed to the upper cross-head. This magnet is also tubular, and the upper carbon-holder could pass freely through it were it not locked in position by the armature of the magnet. This armature is in the shape of a disc, with a hole through it for the carbon-holder to pass. It is kept away from its magnet by a spring, the strength of which can be adjusted to suit requirements, and is also forced against the carbon-holder by a second spring, which tilts it slightly, causing it to bind on the carbon-holder. The electromagnet is arranged as a shunt to the lamp circuit, and normally the current passing through it is not powerful enough to draw down the armature in opposition to the spring holding the latter up. If, however, the length of the arc becomes too long, thus increasing the resistance in the lamp circuit, more current passes through the electromagnet, the armature is then drawn down, carrying with it the carbon-holder, and re-establishing the arc at its proper length. The current through the magnet then falls again below the point at which it is able to attract the armature, and the latter flies back, but is unable to carry with it the carbon-holder, as the weight of the latter is opposed to the motion.

City and Guilds of London Institute. — The report of the council on the work of the institute for the past year has just been issued. At the Central Technical College the number of students has increased, but the present laboratory and workshop accommodation does not allow of any material increase in the number of students in the engineering and physical departments. The diploma of associate of the City and Guilds of London Institute was awarded to 14 students in physics and engineering, and to 13 in civil and mechanical engineering. The highest place in the class list was taken by F. Maeers in the engineering department, and the highest place in the physics department by H. C. Leake. Both of these students were awarded a Siemens Memorial Medal, Lady Siemens having kindly allowed the die of the medal originally presented to the first student in the physics department only to be used also for the first student in the engineering department. At the Technical College, Finsbury, the attendance has fallen off. The decrease was due to the smaller number of second-year students in the mechanical and electrical departments, a larger proportion than usual of first-year students of the previous session having failed to obtain promotion to the second-year course. At the close of the session certificates were awarded nine students in mechanical engineering and applied mathematics, and 23 in applied physics and electrical engineering. The Sir David Salomons scholarship, administered by the Institution of Electrical Engineers, was also won by a Finsbury student. During the year the equipment of the electrical laboratory has been increased by the purchase of the polyphase apparatus used for the transmission of power at the Frankfort Electrical Exhibition. The Mordey alternating dynamo in the electrical laboratory and the new testing machine in the mechanical laboratory, erected at the beginning of the year, and referred to in the Council's last annual report, have proved valuable additions. The total expenditure of the institute during the past year in all its departments has amounted to £30,429. 18s., not including the amount of £275 allocated to scholarships, leaving a balance for the year of £3,545. 16s. 7d., subject to allowance for depreciation on furniture, apparatus, books, etc.

Post Office Electrical Workers.—The *Morning Leader* is responsible for the following: "The workers in the electrical trades have a complaint against the Postal Department, and enter a protest against the methods of payment for their work and the system under which it is carried out. Strangely enough, one of their chief charges is that the method adopted leads to greatly increased cost—in some cases to as much as £3 per lamp compared with the average of £1. 10s. It was only recently that the workers and the taxpayers were congratulated on the fact that the installation at Mount Pleasant had been carried out directly by the Department instead of being given to a contractor; if the particulars given to our representative by the union officials are correct, there is not so much ground for congratulation as one might have hoped. In the first place, it is alleged that the Postal Department employ unskilled labour for a part of the work, and that this necessitates subdividing the work into three portions, a system which causes considerable loss of time. For the first portion of the work unskilled men are employed at what is called cutting the channels, while carpenters are employed at the casing; the unskilled men are then set to work to fit the wires in. In a private firm the whole of the work would be done by one set of men, all of whom would be skilled enough to undertake every part of the work, and to do it thoroughly. Then as to the wages, it is pointed out that the National Telephone Company pay their foremen 45s. and their leading hands 34s., the lowest rate paid being 24s. for the least skilled workmen. In the Postal Department the foreman is represented by the leading hand, who gets only 30s. for working under a Royal Engineer, who is in charge, and who receives 2½d. per hour for his service in keeping the civilian workman out of work. The lower grades of skill are paid for at 18s. to 22s. a week, while the rate at New Cross and other outlying parts are, it is alleged, even lower than that. Another complaint is that when men apply at St. Martin's-le-Grand for work they are asked, 'Do you belong to a trade union?' and if they answer 'Yes,' are not taken on unless urgently required, and are discharged at the earliest opportunity; the reason for this appears to be that the union rate for linemen is 9d. and for chargemen 10d. per hour, and the Department won't pay it, although they compel their contractors to do so."

The Telephone in Rural Districts.—Major-General C. E. Webber writes to the *Times* as follows: "May I occupy a few lines of your space in attempting to show that the telephone as well as the light railway may (in the words of the Queen's speech) be 'found beneficial to the rural districts'? In many countries the telegraph (including the telephone), which is the handmaid of railways, has been their pioneer, often because the capital outlay required for its establishment is comparatively small. As the future fate of the telephone service of this country is at the present hanging in the balance, it seems an opportune moment to

Digitized by Google

draw attention to the question from the point of view of the 'continued seriously depressed condition of agriculture.' The county is the unit of area with which I have studied the subject, and the district round each market town is the natural site of an exchange system, with intercommunication between market and county towns. Some of the advantages of a complete telephone service to the dwellers in the rural districts of a county, through the establishment of a call office in nearly every parish, can be easily realised. To the farmers—the being able to converse with salesmen and customers at the market towns, saving journeys and avoidable movement of stock and produce. To the village tradespeople — the facility of promptly replenishing small stocks. To the inhabitants—the power to converse with the shopkeepers in the market towns for their larger purchases, thus keeping trade within the locality. To the dealers in perishable articles, such as milk and fruit, the value of the advantage is not easy to compute. The distribution of labour and material to meet demand would be better guided and expedited than existing means of communication admit of. Fire-engines and ambulance aid could be promptly summoned to places however remote, and, lastly, the administration of the executive duties of the county council would be enormously helped. I have worked out a scheme for such a rural telephone service in one of the purely agricultural counties, which has nearly 400,000 inhabitants and a gross rental of nearly two millions, and the figures present a very hopeful result. The material used would be what military telegraphers would call 'light permanent line' and of the character largely used in Europe for the telephone. Such a county would require 29 exchanges and call stations at 415 villages and hamlets. The length of pole line required to be erected would be a little over 1,000 miles, and the length of wire to be run a little over 4,000 miles. These figures are exclusive of the lines from private premises to the exchanges, which might in time be reasonably expected to number 700 or 800. The capital outlay would be about £49,000, and the annual cost, including interest, sinking fund, maintenance, renewal, working, and management, would be about £12,200 per annum. These figures are based on cost price as if the work was undertaken by the county council. To cover this a charge of 2d. would be made for each conversation of five minutes within arranged areas, and this must amount to a daily average of takings at each call office of 1s. 11d. The value of the service to the county administration and the net result of the revenue from the private lines would be profit. How far such a scheme would fit into the existing postal telegraph system, or interfere with or help it, is more a question for the Parliamentary Committee now sitting on the subject than for your pages. Without any delegation from them, I venture to advocate the cause of the local authorities in the 120 counties of the United Kingdom."

Electrolytic Reduction of Paranitrobenzoic Acid in Sulphuric Acid Solution.—Dr. A. A. Noyes, Ph.D., and Mr. A. A. Clements deal with this subject in a paper in the *Technology Quarterly* as follows : "In an article published some time ago, we showed that, when nitrobenzene in sulphuric acid solution is submitted to the action of electrolytic hydrogen, the resulting product is not aniline but the sulphonic acid of paramidophenol. That this reaction is characteristic of nitro compounds in general has since been proved by Gattermann, who investigated a great variety of them—nitro-hydrocarbons, nitro-anilines, and nitro-acids—and found them all to undergo change in a similar way, the reduction of the nitro group being accompanied by a migration of one of its oxygen atoms to the para position. Only those compounds in which the para position is already occupied by another element or group than hydrogen form exceptions to this rule. Of such compounds only two were investigated—paranitroorthotoluidine and paranitrotolulene. The reduction product of the former consisted of diamidocresol—CH_3 (1), NH_2 (2), NH_2 (4) OH (5)—a migration of an oxygen atom to the *ortho* position having taken place. In the second case there was obtained a complex body which was shown to result from the condensation of the primary reduction product, amidobenzyl alcohol, with a second molecule of nitrotoluene; thus, in this case, substitution of hydroxyl in the (methyl) group occupying the para position occurs. What reaction takes place seems, therefore, to depend on the nature of the para group, and the investigation of other para compounds in this direction is of considerable interest. We wish to describe here the reduction product of one of these, the paranitrobenzoic acid. We expected to obtain from it amidooxybenzoic acid, or possibly amidobenzoic acid itself; but, remarkably enough, neither of these substances is formed. The paranitrobenzoic acid used was prepared by boiling for one hour with return cooler portions of 20 grammes of paranitrotoluene with 60 grammes of potassium permanganate dissolved in two litres of water, filtering out the precipitate, concentrating the filtrate, and acidifying it. In this way 18 grammes—73 per cent. of the theoretical yield—were obtained. The apparatus used for the electrolysis consisted of a small beaker, to the sides of which a large platinum electrode was closely fitted, and in which was placed a porous cup containing sulphuric acid and a small platinum electrode to serve as the positive pole. The solution, made by dissolving 12 grammes of the nitrobenzoic acid in 100 grammes of warm concentrated sulphuric acid, was poured into the beaker, which was surrounded with asbestos to prevent loss of heat, and a current of one ampere passed through for 24 hours. To isolate the product the solution was diluted with water, cooled, and filtered. The precipitate was found to be very little soluble even in boiling water, showing the absence of sulphates of bases. It was treated with sodium carbonate solution, the residue consisting of sulphur was filtered out, and the filtrate was acidified. A voluminous precipitate separated; it was collected on a filter, and washed first with water, then with alcohol and ether to remove any unchanged nitrobenzoic acid. Four grammes of product were thus obtained. Its properties and analysis showed it to be paramidophenolsulphonic acid. It was only very slightly soluble in boiling water and insoluble in alcohol and ether. It reduced silver nitrate solution in the cold, with production of a purple colour. The solution of its salts turned brown rapidly in the air. It gave the following results on analysis :

	Found.	Calculated for $C_6H_3NH_2OHSO_3H$.
C	37·70	38·09
H	3·75	3·70
SO_3	42·40	42·33

To give further proof of the identity of the acid, some of it was heated to 175deg. in a closed tube with concentrated hydrochloric acid. At this temperature the sulphonic group was split off, as is the case with the paramidophenolsulphonic acid. The hydrochlorate, which crystallised out on cooling, was filtered off, dried, and boiled with a large excess of acetic anhydride. The resulting product, after crystallisation from water, showed a melting point of 152deg., identical with that of diacetylparamidophenol. The electrolytic reduction product of paranitrobenzoic acid is, therefore, paramidophenolsulphonic acid, the tendency of the oxygen atoms to assume the para position being great enough to expel the carboxyl group originally occupying it.

LEICESTER ELECTRICITY WORKS.

This town is one of the most ancient in the annals of our history, and it is a happy augury to see an ancient historical town still striving to be amongst the very front rank of those whose municipal affairs are a pattern to their neighbours. Leicester was a prominent town before the Roman occupation; it became a Roman station of importance, nor did its influence lessen under the Saxons, whose name Legerecastre in a contracted form is the name of the town to-day. It is a busy hive of industry, with a world-wide reputation for its manufactures—principally hosiery, lace, and boots. It has enjoyed its municipal privileges since the time of King John, who gave its first charter, while succeeding sovereigns confirmed and extended the charter. During the recent revival of municipal activity Leicester has not remained idle, but has secured the control of the water and the gas supply, and, lastly, has entered into the great work of electric supply. We might also just mention that its sanitary work has been extensive, and carried out under engineers of the very first rank, such as the late Mr. Gordon and the present borough engineer, Mr. Mawbey. The development of the artificial lighting, as will be better understood later on, has been of recent years in the able hands of Mr. A. Colson, M.I.C.E., the borough gas engineer.

The engineer has had the full confidence of the Gas and Electric Lighting Committee, consisting of:

ALDERMAN LENNARD (CHAIRMAN).

MR. BILLINGS (VICE-CHAIRMAN).	MR. JENNINGS.
MR. BENNION.	MR. MAJOR.
MR. BOOTH.	MR. ORTON.
MR. BRUCE.	MR. PAYNE.
MR. J. T. CLARKE.	MR. POCHIN.
ALDERMAN COLEMAN.	MR. ROWLETT.
MR. COWLING.	MR. SMITH.
MR. EDWARDS.	MR. SPURWAY.
MR. FAIRE.	ALDERMAN WOOD.
MR. FLINT.	MR. H. H. WOOLLEY.

The Corporation of Leicester when they first contemplated supplying electric energy in their town determined that the whole of the work should be left in the hands of the borough engineer, Mr. Alfred Colson. His decision as to the system of supply and general type of plant was to be final, and it must be admitted from the following description that the confidence shown by the Corporation in their engineer was not misplaced. Mr. Colson was placed in charge of the gasworks at Leicester about 12 years ago, and has converted a marshy swamp often 3ft. under water into the site of one of the most complete gasworks in the kingdom.

The growth of the works under his care may be gathered from the money spent, which has in the time amounted to some £300,000, and better still from the plan, Fig. 1, which shows the extent of the works at the present time. As will be seen from it, the Corporation now possess the whole of the artificial lighting works necessary for satisfactorily and economically illuminating their town. At the gasworks there are most extensive coal stores, which should prevent the Corporation feeling any inconvenience in either the electric lighting or gas departments when unfortunate trade disputes arise in the coal industry. In the extensive chemical works the by-products of the gas production are carefully worked up into their most marketable state. The general appearance of the whole of the works is most pleasing to the engineering eye, and the library, in which the guests of the Corporation were entertained after the opening ceremony, shows the consideration shown to the employés. The library is well furnished with books and recreative games, and some 150 persons can be comfortably seated in the room.

Mr. Colson, having had a large general engineering experience, had the whole of the steam production and engineering details at his fingers' end, but he determined to make himself familiar with the electrical branches by undertaking the new work. So after seeing all the principal electric light stations in England, he travelled on the Continent with the same end in view. Mr. Colson's final decision was that in some points the foreign practice was likely to give less trouble in working, and also a longer-lived plant. The question of the speed and type of the engine was the special point in which he differed from most of the English contractors. They have been obliged by competition to cut down the first cost to its lowest limit, and, as also in many cases, the floor space as well. The result is that in the great majority of the electric light stations in England high-speed direct-coupled plants are used, and in others high-speed vertical engines with rope or belt gearing. With direct-coupled plants the cost of the electric generation also varies in the inverse proportion to the speed, and hence speeds below 200 revolutions are almost unknown except on shiplighting plants.

Taking the Cologne station as his general type, Mr. Colson determined to use the ordinary horizontal engine with Corliss valve gearing and to make the alternator take the place of the flywheel. Amongst the designs sent in to meet this requirement were some of the alternators since adopted and installed at Portsmouth, so that Mr. Colson may fairly be considered the moving spirit in the introduction of this class of machinery into English practice. So, as is often the case, we find again that the engineer to introduce a new type in an industry is one who approaches the requirements of that industry without prejudice and untrammelled by preconceived notions as to the way any operation must be done. The same individuality in design which we refer to above will be apparent to all our readers from the description and illustrations of the Leicester electric lighting station which follow. The whole of the design and outfit, even to the smallest detail, shows most careful personal attention on the part of Mr. Colson. The result is one of the best electric lighting plants in England, which from its position and outfit should enable the light to be supplied profitably at even less than 6d. per unit. The historical development of the work at Leicester is briefly as follows, and in it the engineer was very ably assisted by the members of his committee.

In August, 1889, the Town Council decided to apply for a provisional order for the supply of electricity, which was granted in the following year. In July, 1892, the Gas Committee, having also been appointed the Electric Lighting Committee, advertised for tenders, plans, and specifications for the supply of electricity. Although certain lines and conditions had necessarily to be laid down and conformed to, the contractors in the preparation of their schemes were allowed considerable latitude. Broadly, the invitation issued was for complete schemes and tenders, together with specifications and general drawings for the generation and distribution of current for a specified number of lamps assumed to be about evenly distributed throughout the "limited area"—that is, that portion of the borough bounded by Belvoir-street, Welford-place, Pocklington's-walk, Berridge-street, Grey Friars, Loseby-lane, Cart's-lane, High-street, Eastgates, Haymarket, Gallowtree-gate, and Granby-street—an area of 36,300 square yards, and comprising the centre and best business part of the town. The site for the generating station, the system of supply, the method of distribution, and kindred matters were left to the discretion of the competitors. They were to provide in their schemes and tenders for such reserve plant and apparatus as they deemed necessary. In preparing their plans and estimates the competitors were to bear in mind that, although the Corporation would go to no needless expense, on the other hand their object would not be to obtain the cheapest installation irrespective of its merits. The endeavour would be primarily to secure such an installation as would comply with the following conditions: (*a*) Perfect safety—*i.e.*, so far as science could render it, free from danger to life and property. (*b*) The generating station to be placed as to avoid every risk of nuisance or annoyance from vibration, etc. (*c*) The system to be thoroughly elastic—*i.e.*, capable of easy extension without extravagant outlay. (*d*) The method of distribution such as to necessitate as little interference as possible with the streets and roadways, not only when first laid down, but also in the case of renewals or deficient supply of current. (*e*) Every portion of the scheme and apparatus in connection therewith to be well beyond the experimental stage, of thoroughly approved efficiency, and to be of the very best description both as regards material and workmanship; the machinery to be

of such design as to reduce the wear and tear and risk of breakdown to a minimum.

In reply to the advertisement, 17 competitors submitted 25 schemes and tenders, several offering alternative plans. In all there were six systems recommended as follows: direct high-tension alternating-current, with house transformers, 4; direct high-tension alternating-current, with outside house transformers, 1; high-tension alternating-current, with street transformers and low-tension distribution, 15; high-tension continuous-current, with street transformers and low-tension distribution, assisted by accumulators, 2; low-tension, with accumulators, 2; low-tension three-wire system, with accumulators, 1. As to site, 14 competitors recommended the Aylestone-road Gasworks, and three were in favour of the works being placed in the town within the limited area.

In January, 1893, the engineer submitted his report upon the schemes and tenders, and in the following month that of the Brush Electrical Engineering Company, with certain modifications suggested by the engineer, was, upon the recommendation of the Gas Committee, accepted by the Town Council. The contract entered into was for the supply of the whole of the electrical plant and boilers. The order for the engines was ultimately placed with Messrs. Hicks, Hargreaves, and Co., of Bolton. In August of the same year the usual Government enquiry was held, and in the following month sanction was obtained for the expenditure of £42,574 in connection with the work. This amount is estimated to cover, not only the cost of the present installation, but also a further extension of cables. The system adopted was the high-tension alternating-current, with street transformers and low-tension distribution.

The Central Station.

The central station is situated about 1½ miles from the centre of the town, at the gasworks on the Aylestone-road. It stands on the left-hand side of the main avenue running through the works. The whole of the foundations and buildings have been carried out from designs by the engineer, and with his own men, no contractor having been employed. It is a red-brick structure, corresponding in its general features with the buildings of the gasworks, and comprises vestibule, engine and dynamo room, boiler-house, office, and testing-room, Fig. 2. The vestibule is 18ft. by 13ft., with a mosaic floor and tiled dado. It is entered by half-glass folding doors, with a similar pair leading therefrom into the engine and dynamo room.

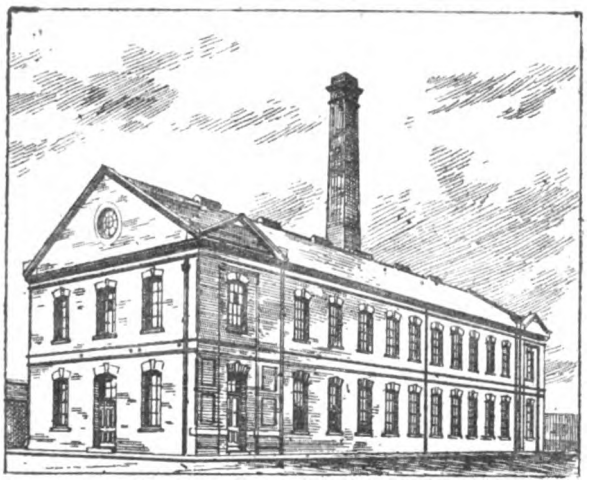

FIG. 2.—View of the Electric Light Works at Leicester.

This, the main feature of the building, is 114ft. long, 40ft. wide, and 31ft. 6in. high, lighted with a double tier of windows on both sides, except where the boiler-house abuts, and one end. The roof is supported by wrought-iron principals and formed of pitch-pine rafters and purlins filled in with diagonal matchboard panels, as will be seen from our illustrations. The floor is formed of rolled-steel joists filled in with cement concrete, and paved with tessellated tiles. A dado encircles the room formed of matchboarding, with moulded cap and skirting, the whole being stained and varnished to correspond with the roof. The generating plant consists of three Mordey-Victoria alternators, each of 200 kilowatts capacity, coupled direct to three horizontal compound condensing engines, each of 350 i.h.p. Both cylinders are steam jacketed and fitted with Corliss valve gear. The governors are unusually large and powerful, and control the gear on both cylinders. The engines run at 96 revolutions per minute. Each engine is provided with a jet condenser and an air-pump worked by a rocking beam attached to the low-pressure piston rod. In addition to the large alternators, there is also a small machine intended for the light or day load. This has a capacity of 75 kilowatts, and is driven by a 135 i.h.p. engine of similar construction to the larger engines, except that Corliss valve gear is not provided for the high-pressure cylinder and the high-pressure cylinder only is governed. This engine runs at 120 revolutions per minute. The exciters consist of two Victoria continuous-current dynamos, each of 13 kilowatts capacity. Adjoining the engine-room is a workshop measuring 26ft. by 18ft. When finished it will be fitted with a complete set of machine and other tools. Over the vestibule and shop is an office and testing-room, reached by a spiral staircase, and measuring 41ft. by 18ft., with a roof corresponding to that of the engine and dynamo room. Here will be fixed all the testing instruments and apparatus required in connection with the station. From this office access is gained to a balcony overlooking the whole of the machinery.

The general arrangement of plant is shown in Fig. 3.

The boiler-house stands at the rear of the main building, the back wall of which is common to the two. It measures 55ft. by 42ft., and contains four Babcock and Wilcox tubular boilers, each of 250 nominal horse-power. These work at 120lb. pressure. Foundations are already in for two more boilers of like size. The feed water is supplied by two three-throw pumps, each with engine attached, through a Babcock and Wilcox economiser, placed in the main flue leading to the chimney. The fuel at present employed is coke from the gasworks. In one corner of the boiler-house is fixed an Evans duplex pump for pumping water, for feed and other purposes, from the river into an overhead tank placed in the adjoining chemical works. The water for condensing is taken direct from the river, the difference in levels fortunately allowing this to be done. The three openings into the boiler-house are protected by revolving shutters. The draught is obtained from a stack 125ft. high.

On either side of the station are railway lines in direct communication with the sidings at the gasworks. These afford great facilities for the delivery of plant and apparatus, as well as fuel for the boilers.

No little difficulty was experienced in connection with the foundations for this work. This arose from the close proximity of the site to the River Soar and to the subsoil consisting of peat, running sand, or silt. To avoid the slightest risk of settlement in any part of the work, the whole of the foundations were carried down to a depth of 22ft.—viz., to the Keuper bed, which consists of good hard red marl. The foundations of the walls of the building are of blue lias lime concrete, while those for the engines and alternators are composed of Portland cement concrete and brickwork in cement. The beds for the whole of the machinery are formed of best Derbyshire stone.

The whole of the distribution systems, both high and low tension, consists of Fowler-Waring concentric cables. From the central station, Fig. 4, two high-tension cables, iron armoured and lead covered, are laid naked in the ground at a depth of 2ft., and run direct to No. 1 transformer-chamber situated in Market-street. From this chamber the high-tension mains are drawn in 3in. cast-iron pipes, and form a ring encircling the limited area. By means of switches placed at two points in this ring, the circuit can be divided into two sections for the convenience of testing and making alterations and connections.

The low-tension mains are of one section throughout—viz., ·146 square inch—lead covered and armoured, and laid naked in the ground at a depth of 2ft. The house service connections, also concentric, are teed direct to these, a lead joint being wiped on to ensure the lead covering remaining intact, the whole being armoured by a cast-iron tee clamp.

Digitized by Google

The transformer chambers are eight in number, their internal measurement being 7ft. 6in. long, 5ft. 6in. wide, and 7ft. high. The sides and ends are cambered, having a rise of 6in. The walls of the chambers are formed of good hard bricks in cement in two thicknesses, with an inch space between. This space is filled in with specially prepared asphalte, which is also continued under the paving of the floor as well as over the roof, thus making the chamber perfectly water and gas tight. The roof is formed of rolled-steel joists filled in between with cement concrete. A suitable manhole with double cover is provided for access to the chambers, which are descended by means of step-irons built into the inner thickness of wall. All the chambers have an air inlet and outlet for securing proper ventilation. The bellmouths of the pipes carrying the high-tension mains are caulked with Vulcan cement, with the object of preventing any gas finding its way into the chambers. As an additional precaution against this occurring, the pipes are provided with a ½in. hole about 1ft. from the back of the wall of the chamber, which communicates with a ventilating flue. This arrangement allows any gas which finds its way into the pipes escaping before reaching the chamber. A similar arrangement with the same object is provided in connection with the low-tension cables.

Although the official inauguration of the works is only taking place this week, the light was first supplied to the town on December 19 last. At present no cables are laid beyond the limited area, but recently the Gas Committee decided to carry these through Stoneygate—the residential quarter—for a distance of something like two miles. The total number of meters fixed is 91, and lamps wired equal to 6,000 8-c.p. The price at present charged is 6d. per unit. In connection with this work has been organised an electric light fitting department, which has carried out about four-fifths of the total installation work in Leicester. The profit from this goes towards reducing the loss at present incurred in supplying the light. A suitable showroom at the gas offices is well stocked with the best of everything obtainable in the way of fittings.

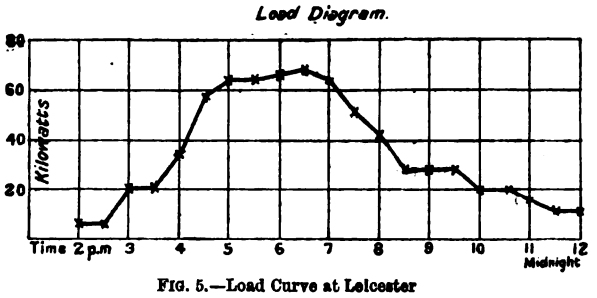

FIG. 5.—Load Curve at Leicester

The present demand for lighting is satisfactory when it is considered that the supply was only commenced at the end of December. The curve which we give, Fig. 5, was taken on January 8, 1895, and shows a maximum load of 78 kilowatts and a total output of 360 Board of Trade units for the day. Judging from the population and the number of high-class streets in Leicester, we believe that this load will rapidly increase till the full capacity of the station is exceeded.

Owing to the large number of special features needing description in the machinery of the station, we are compelled to hold the detailed descriptions over till our next issue.

The formal ceremony of opening this installation took place yesterday, when Councillor BILLINGS, on behalf of the Corporation, congratulated the committee upon the success of its efforts during the last six years. He especially congratulated both the chairman and the engineer upon the successful completion of their arduous labours. He pointed out that Alderman Lennard had during the six years directed the deliberations of the committee, and that they had spared no pains in collecting all the information they could upon the subject; while their engineer, Mr. A. Colson, had visited almost all the English and continental stations, and after carefully examining them, selected what he thought to be the best system. Now they had the electric light at work in such a manner that the safety of life was assured so far as humanity could practically assure it, while thorough efficiency and durability had been aimed at throughout the design.

Alderman LENNARD then gave the company a hearty welcome, and entered into an explanation of the works at which they were assembled. He alluded in the first place to Faraday's experiments, and pointed out that these formed the germs of the present magnificent apparatus which were there installed. They had before them engine room to the extent of something like 1,185 i.h.p., capable of supplying over 11,000 16-c.p. lamps; allowing one machine to be kept in reserve, they could supply 8,000 such lamps. The position of the station was very suitable, for they had an ample supply of water and ample room for coal storage. The foundations of the building presented some difficulties, seeing they were about 22ft. below the floor level, but their engineer had made them perfectly satisfactory. It was Mr. Colson who had designed the first direct-coupled flywheel alternator, which was shown in the gas office some three years ago. Although another corporation had started similar plans previously, he (their engineer) certainly originated the type in England. He then asked the visitors to walk round the station, and called upon Mrs. Lennard to start the engines.

Mrs. LENNARD, who formed the centre of a picturesque group, then successfully started the engines amidst much applause, after which the company adjourned to luncheon.

The luncheon was served in the library at the works, at which Mr. Lennard presided, there being about 130 guests present.
